In speaking of the London porter, one of the most popular lecturers on food says that that beverage (of which there are prodigious quantities consumed) is miserably drugged in the public-houses. Its strength is reduced by water, and its qualities are brought up again by treacle, liquorice, and salt, and various narcotic agents which are added to make up for the loss of alcohol. To such a condition has the porter-drinking population been brought, that they do not know genuine porter when they drink it, and having acquired a taste for its wretched substitute, they reject the unadulterated article.

The specimen examined may be viewed as the type of a pure beverage, and where the desire for fermented malt liquors is indicated by natural taste, few beverages would combine such nutritious value with mild stimulating properties.

In drinking a glass of porter (½ pint) similar to that analysed, the consumer takes in about 1½ ounce of pabulum (including the alcohol) of easy digestibility. In stimulating property, a glass of Guinness's porter of the above quality is equivalent to one-half of its bulk of moselle or good claret, a wine-glass of sherry, or an ounce of brandy.—MEDICAL PRESS, Dec. 15.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

PROTOPLASM AND THE GERM THEORIES.

DR. CHILD, remarked upon this subject that protoplasm was as a rule a more or less viscous fluid, consisting mainly of the four elements—oxygen, hydrogen, carbon, and nitrogen—such as constitute the living portion of every organism, animal or vegetable. Some portion of these substances is decomposed by every action of life in the organism in which it exists. It is capable of repairing the loss thus occasioned by assimilation to itself with new matter derived directly or indirectly from the inorganic world. We are unable by any process to discriminate between the protoplasm of the lowest plant and that of the highest animal; but, as a matter of fact, the protoplasm of one kind of organism so far differs from another as to conform to peculiarities of type. The protoplasm of a fungus in its early state, for instance, developed into an adult fungus, and never took another form. The earliest discoverable state of every organism is that of a simple minute mass of protoplasm, and beyond this stage many organisms never progress. Organisms are capable of reproduction and multiplication by means of detached portions of their protoplasm. Those eight propositions would be sufficient, with the help of one other which is very generally admitted—that while vegetable organisms are capable of assimilating to their protoplasm certain inorganic compounds, the animal world has to find its nutriment ready made from the vegetable kingdom. What he had to call attention to was the various germ theories which had been put forward. After an examination of the experimental evidence put forward, Dr. Child said that the conclusions which he had arrived at on the theoretical relation of the question of abiogenesis, were that it appeared to him that abiogenesis in some form or other was a necessary consequence of certain other theories which were gaining ground at the present moment, such as the origin of species and the theory of evolution. It was hardly conceivable that we could theoretically hold that the original simple forms from which the whole animal and vegetable world had been developed, had sprung into existence out of the regular order of the evolution of the universe. What was called the germ theory of disease threw an interesting light on the question. Zymotic diseases were now generally believed to result from the multiplication or reproduction of germs in the blood of the man or animal affected. The matter to be accounted for was how the germ diseases appeared, disappeared, and afterwards again cropped up in the same district and at great intervals of time. If the old theories were to be maintained in their entirety as to the fixity of species, every one of these diseases must have existed somewhere from the beginning. That was a view which was hardly credible, but that it was held he proved by a quotation from a work by Dr. Budd, of Bristol. On the other hand the view derivable from the process of evolution would be simply that wherever certain different degrees of complication in the structure of the earth's crust arise, we should find the same reproduction of minute organic beings, and probably this process was taking place at different times in different parts of the world exactly as favouring circumstances occurred.

Mr. Samuelson read a paper "On the Controversy on Spontaneous Generation."

Mr. Samuelson's paper comprised a comprehensive view of the present position of the controversy on heterogenesis, or the supposed creation of the lowest forms of plants and animals *de novo*. He thought the importance of the theological bearing of the subject had been overrated, and expressed his belief that those who adopted the theory of the creation of living forms only from germs already in existence would eventually find their view to be correct. Proceeding to criticise the labours of Dr. Bastian, Mr. Samuelson characterised as vague the terms in which that gentleman had described the results of his experiments. He also showed that some of them were opposed to the results he (Mr. Samuelson) had obtained. From a series of experiments extending over many years, he had little doubt that the plant types really spring from atmospheric germs. In 1863 Mr. Samuelson found the same plant types—various stages of mildew—in infusions of orange juice, cabbage juice, and pure distilled water exposed to the air; and during the past summer he again found the identical types in infusion of orange juice, and in water caught in a shower of rain. At both periods he found lowly animal types in the atmosphere. Leaving the results of his experiments to the judgment of men of science, Mr. Samuelson said that if the believers in spontaneous generation still insisted that their hypothesis had not been refuted, he would retort that their experiments had only proved so far their inability to exclude invisible germs from their infusions.

The Chairman intimated that if it was the wish of the audience, Dr. Crace Calvert's paper relating to fermentation, which had been entered in another department, might be read with advantage in this. (Applause.)

Dr. Crace Calvert referred to some experiments which he had completed, and to another series on which he had been engaged for the last twelve months, and which were likely to take him another twelve months to perfect. His endeavour was to take air from the breath of patients suffering from typhoid and scarlet fever and small-pox, to examine that air, and see what kind of microscopic life such breath conveyed. The first part of his experiments had led already to some interesting results, and they entirely proved the truth of Dr. Tyndall's and Mr. Samuelson's statements. He had already established the possibility of preserving air from microscopic life for seventeen days, and by the new plan he was pursuing he would be able to show that germs might be excluded for twelve months. He stated the facts demonstrating that the atmosphere contained germs of putrefaction, and that the rapidity of the development of the germs depended on the nature of the pabulum with which they came in contact. So that these phenomena, though appearing at first sight to have a similarity, differed greatly in their mode of reproduction. Dr. Calvert hoped to be able to lay the result of his experiments before the meeting next year, and observed that if he should be so successful as to announce the fact that there was a distinction between the vital life from the breath of fever patients or those suffering from small-pox, he was conscious that he would have conferred on society a great boon. (Hear.) Speaking of the difficulties attending the investigation, he said the microscope which he used magnified 1,600 times, and it required the highest power to be able to follow the microscopic life. There were little cells which could not be seen at all except by the most careful attention and by practice, and they moved about with such rapidity that he could barely follow them. He had never seen this class of cells except in connection with putrefaction.

Mr. Bentham, President of the Linnæan Society, in opening the discussion, remarked that there were two essential conditions to be observed by experimenters—accurate experiments, and sound reasoning upon them. His opinion was that the experiments as to the existence or non-existence of germs could not be taken as conclusive; they must depend altogether upon circumstantial evidence. The germs which floated in the air could not be seen by any microscope, and their presence or absence must be deduced from other circumstances. He expressed his confidence in the experiments made by Mr. Samuelson. At one time abiogenesis was supposed to exist wherever there was corruption. That theory was not now believed in. There was no case in which animals in their early state were visible to the microscope where it had not been proved that they had been derived from living animals. And what they had all just heard went to prove that, reasoning by analogy, there was no ground at present for supposing that abiogenesis exists.

CURIOUS EXPERIMENT IN MAGNETIC INDUCTION.

Mr. S. A. Varley exhibited a very curious experiment, in which a bar of soft iron which normally possessed no magnetism lifted pieces of soft iron off the poles of a strong permanent magnet, yet it was clear that all the magnetism in the soft iron bar must have been derived from the permanent magnet below. He then explained that according to the laws of magnetic induction, this must necessarily be the result of such an experiment.

In the Section Anatomy and Physiology, the following papers were read :—

The report of Dr. Arthur Gamgee on the heat generated in the blood in the process of arterialisation, which was of a purely scientific character, having been taken as read, Professor Traquair contributed a paper on "The cranial osteology of *polypterus bichir.*" Professor Macalister exhibited a sketch of some varieties of the *pronator quadratus*, and at great length explained their peculiar characteristics. Professor Cleland followed with a communication on "The physical relations of consciousness and the seat of sensation—a theory proposed," and the business of the day concluded with a paper by Dr. B. W. Richardson on "New physiological researches on the effects of carbonic acid." He explained that the observations he had made were new in that they related to the direct action of carbonic acid on animal and vegetable fluids, and they were interesting equally to the zoologist and botanist as to the anatomist. But the greatest interest concentrated on the relation of the research to some of the diseases of the animal body. Thus, in instances where the temperature of the body is raised and the production of carbonic acid is excessive, the blood on the right side of the heart has its fibrine often precipitated, and in many other cases fibrinous or albuminous exuded fluids are solidified, as is the case in croup. The author, in the course of his paper, explained how rapidly blood charged with carbonic acid absorbed oxygen when exposed to that gas, and he held that carbonic acid in the venous blood was as essential to the process of respiration as was the oxygen in the pulmonary organs.

SPONTANEOUS GENERATION.

At a meeting which was held in the reading room at the Free Library, Professor Rolleston presided, and the attendance was unusually large, the great attraction being Dr. Bastian's reply to the two objections of Professor Huxley relative to certain experiments made in the investigation of the theory of spontaneous generation. Professor Huxley, in his inaugural address, referring to these experiments, said the first reply which suggested itself was the probability that there must be some error about them, because they were performed every day on an enormous scale with quite contrary results—meat, fruits, and vegetables, the very materials of the most fermentable and putrescible infusions being preserved to the extent of thousands of tons every year by a method which was a mere application of Spallanzani's experiment. Did the professor, Dr. Bastian asked, presume that these preserved meats were free from living organisms? The ordinary method of preserving meat in cans, as practised at Mr. M'Call's establishment in London, was this—Large numbers of the cans containing meat, and having only a small aperture in the top, were placed in a bath containing a solution of chloride of calcium capable of being heated to 263 or 264 degrees Fahrenheit before it boiled, and they were submitted for more than an hour and a-half to a heat of 230 degrees Fahrenheit, corresponding with 110 degrees Centigrade, a temperature which Pasteur considered sufficient to destroy any pre-existing life which might be in solution. Afterwards, the tins having been hermetically sealed, the temperature was rapidly raised to 260 degrees Fahrenheit, equivalent to 126 degrees Centigrade, and this temperature was maintained for half-an-hour. Mr. M'Call assured him that there was a certain definite percentage of failures in meat so preserved. Some of these were undoubtedly to be explained by defective closure of the cases, but on the other hand, there were a certain number of failures where it was possible to find no flaw or defect whatever in the tin. They might remain good for two or three years, and then from some unknown cause they were found to become putrid, which was always known by a bulging out of the ends of the tin, caused by the generation of gas inside. Wishing to ascertain the microscopic condition of meats sold as perfectly good, he procured three tins, one of salmon, one of lobster, and one of Jullien's soup. He opened them, and submitted their contents to microscopic examination, and found in each of the tins a very great number of the minute living things which were met with in solutions, and which he supposed to be capable of coming into existence *de novo*. These living things consisted of minute figure-of-eight particles, *bacteria* like bodies, and filaments. As far as the filaments were concerned, they made no movement, but there was no reason to suppose they were dead. With regard to the movements exhibited by the figure-of-eight particles, there were certain Brownian movements supposed to be due to certain physical conditions of the fluid itself, and there were other movements which were unmistakably vital, and between these two extremes there were any number of conditions. It was quite possible to meet with *Bacteria* which were really living, but which, nevertheless, showed only languid movements. It was impossible to draw any sharp line of demarcation. They could not say positively when these slow movements existed that the thing was living, but on the other hand, they had no positive right to infer that they were not living. Then Professor Huxley said—"If, in the present state of science, the alternative is offered to us, either germs can stand a greater heat than has been supposed, or the molecules of dead matter, for no valid or intelligible reason that is assigned, are able to rearrange themselves into living bodies, exactly such as can be demonstrated to be frequently produced in another way, I cannot understand how choice can be, even for a moment, doubtful."

By this, he presumed, Professor Huxley meant that if these alternatives were put, he would decidedly elect to believe that the germs could stand the heat to which they had been subjected rather than that it was possible for the living things to have been originated *de novo*. Now, his own experiments, at all events, were so simple in their nature, that it did not seem to him that there was very much room for the possibilities of error suggested by the professor. Certain flasks containing solutions were taken—in some cases of organic and in others of inorganic matter; they were hermetically sealed by Professor Frankland; and then they were exposed to a temperature of from 146 to 153 degrees centigrade. He supposed that this amount of heat would destroy the germs if they were in the flasks, and that the finding of living things in the solutions afterwards would be evidence that they were produced *de novo*. He examined the flasks day after day with the greatest care, and saw nothing until the expiration of about three weeks, when certain cloud-like flocculi appeared in the solution, and after about three weeks more there appeared on one of the flocculi a minute white speck, which, though small, increased in size day by day; and when the flask was opened at the expiration of sixty-five days, the whole white mass was found to consist of fungus spores and filaments. In order to ascertain the possible effect of such a heat as the solution had been submitted to on fungus filaments, he took certain fungus filaments and spores from an organic infusion and submitted them to the same test, under precisely the same conditions; and when he examined that fungus mass afterwards he found that it was completely dissolved. There was scarcely a perfect and entire fungus filament to be seen; there was not an entire spore. In the face of that evidence he did not think it was very hard that it should be maintained that the fungus he found in the first instance was a fungus which had existed in the solution before. It had never yet been shown that any living thing could continue to live after it had been exposed to a temperature of eleven degrees centigrade; and it was because he had found living things in infusions which had been submitted to a greater heat that the evidence seemed to him at present—and that was all he said—to be decidedly in favour of the view that the living things he found in those solutions had been evolved *de novo*.

Dr. CHILD said Professor Huxley, and those who thought with him, took their stand on M. Pasteur's experiments, and if those did not hold good the whole of their evidence was swept away. They were on the horns of a dilemma. Either these living things were spontaneously produced, or they could withstand the boiling temperature. If they could withstand the boiling temperature, M. Pasteur's experiments were swept away; and if they could not withstand it, then they must be spontaneously produced.

Mr. EDDOWES remarked that the contents of the cases of preserved salmon and lobster had never reached the boiling point. They were not prepared by Mr. M'Call, or by the process which had been described, but were prepared on the Canadian coasts in a very rough way, and never kept for any length of time. He suggested that Dr. Bastian should analyse the contents of a case prepared by Mr. M'Call, and he could let him have one which he had had in his possession for fourteen years, and off the contents of which he was prepared to lunch that morning.

Professor TYNDALL said Dr. Bastian's experiments—conscientiously, earnestly, and laboriously conducted as they had been—had not produced the slightest effect on his views. Dr. Bastian had raised further barriers, obstacles, and objections which could not be met by any argument that could be brought before that meeting. They must be met by a strict scrutiny of his experiments—by going over the same ground; and he would invoke Dr. Bastian himself, in the interest of the subject, to repeat his experiments, multiply them, and seek for negative causes. If he understood aright, Dr. Bastian prepared his flasks by partly filling them with solutions or infusions. They were, he believed, about half filled. (Dr. Bastian: About that.) Then above the solution there would be air, and this, he understood, was removed by means of an air-pump; but he assured Dr. Bastian that it was perfectly impossible for the air-pump to remove the germs or dust particles, or whatever they might be, with which the air was charged, and he should like to know whether the precaution was taken to turn the flasks upside down whilst they were exposed to the heat, so as to submerge these particles in the heated liquid, because the germs might be able to sustain a much greater amount of heat in a gaseous form than in a liquid form.

Dr. BASTIAN said the flasks were frequently shaken.

Professor TYNDALL thought that was not enough. Dr. Bastian would have to repeat his experiments before they would be of any value to anybody who required strict proof.

Dr. BASTIAN.—What I maintain is that, so far as our present state of knowledge goes, the evidence is in favour of spontaneous generation.

The CHAIRMAN said, with reference to all these experiments with heat, it seemed to him that the analogy of albumen, which, after it had been exposed to the action of the digestive juice, was no longer amenable to the action of boiling water, was a great light. It was possible that the limit of endurance of heat by vitalised albumen had not been gained. Peptone was a highly complex organised albumen, and, nevertheless, it was not acted upon by heat at all. Taking a large view of the whole question, he was rather prejudiced against the theory of spontaneous generation.

THE PREVENTION OF LEAD-POISONING IN WATER.

Mr. ALEXANDER GORDON read a paper entitled "How to Prevent Lead-poisoning in Water." He first pointed out that though medical and scientific men had long been unanimous as to the desirability of abolishing lead as a means for the storage or distribution of water used for dietetic purposes, the conviction as to its danger had not yet fully forced itself upon the public mind. The result was that though hundreds and thousands of pounds were spent in obtaining pure water, in a great many cases the water no sooner crossed the threshold of our houses than it became poisoned by means of leaden pipes and cisterns. Various substitutes for lead piping had been tried, but all were more or less open to objection either from the danger of rust, the want of ductility, liability to galvanic action, or other causes. The only substitute yet manufactured which, while it conserved the purity of the water, was both ductile and cheap, was that invented by Mr. Haines, C.E., and specimens of which Mr. Gordon displayed. It consists of a leaden pipe with an internal pipe of block tin, both having been previously pressed together so as to form a homogeneous whole. By this process the piping retained all the flexibility of lead, while the inner tube of tin was strong and thick enough to prevent any access of water to the exterior leaden pipe. Mr. Gordon stated that wherever the invention had been applied its sanitary value had been found perfect. The manufacture was daily increasing, and its merits were being recognised not only in this country but in foreign countries.

The PRESIDENT said that a number of experiments were made a few years since by the Sanitary Association of Manchester, the result of which, he believed, was that no coating of tin applied in an ordinary way was sufficient to prevent the action of the water on the lead: but, according to the plan explained by Mr. Gordon, a thicker coating of tin appeared to be applied, and that seemed to be a solution of the difficulty.

ON THE USE OF DELIQUESCENT SALTS FOR LAYING DUST.

Mr. W. J. COOPER read a paper on "The Use of Solutions of Soluble Chlorides for Laying Dust in Thoroughfares," observing that at the meeting of the British Association at Norwich in 1868, he introduced the subject of the application of deliquescent chlorides for that purpose. At that time an experiment had been tried in Baker street, Portman square, throughout an exceptionally hot season, with most successful results, the surface of the macadam road being purified, hardened, and concreted, and the obnoxious dust prevented from rising. In Liverpool, in the year 1869, Bold street, Church street, and Lord street were watered with salts during the month of July; the report of the results was very favourable, and the experiments had been continued this year. It was difficult to prove the economy resulting from the use of the chlorides over a limited area, and the Westminster Board of Works, after observing the effect, resolved to extend the experiment throughout their entire district, comprising an area of 250,000 square yards, and no sooner was that course adopted than the economy in labour and water was evident. Mr. Cooper also remarked that the importance in a sanitary point of view of the use of the chlorides had been clearly established, and he argued that an effective method of remedying the evils arising from organic matter deposited on public thoroughfares was daily becoming a matter of serious consideration with sanitary authorities.

Abstracts of Lectures

DELIVERED AT THE

LONDON MEDICAL SCHOOLS

AT THE

OPENING OF THE WINTER SESSION, 1870-71.

ST. THOMAS'S HOSPITAL SCHOOL OF MEDICINE.

Abstract of address delivered on Saturday, October 1st, by HENRY GERVIS, M.D., Lecturer on Forensic Medicine to the Hospital.

After some introductory remarks and words of welcome to the entering students, Dr. Gervis proceeded to say:—It has been somewhat the fashion of late to depreciate the importance of attendance upon lectures. From this my own recollections of student life lead me to disagree. I still remember the very forms of expression which characterised the lectures of our various teachers—nay, the very sound of their voices still lingers in my ear. The power of the lecturer is akin to that of the speaker and preacher; and as to listen to a Disraeli or a Bright in the House of Commons, or to a Liddon or a Guthrie in the pulpit, is a much higher treat, and far more impressive than to read their speeches or sermons in print, so do I think a lecture listened to is far more impressive than a lecture read. In conjunction with note-taking, of whose utility Dr. Gervis spoke highly, he alluded to the medical parliamentary measure which, had it been enacted, would have made the year so eventful a one to the profession. With respect to it, Dr. Gervis expressed an opinion adverse to the three board system, but yet thought that after the plan of the London Matriculation Local Examinations could be held simultaneously in the three divisions of the Kingdom, and in this way the same level of examination be everywhere maintained, and no invidious distinction drawn between the value of the three diplomas. Some questions connected with the out-patient departments of the metropolitan hospitals and the mutual relationship of school and hospital were then alluded to; on the latter point Dr. Gervis said:—By the union of a school with the hospital we believe the benefits of the hospital are largely extended and multiplied; not only does the hospital get for its in-patients an amount of medical and surgical aid from educated and zealous attendants, such as but rarely, at all events, could ordinary paid nursing replace, but without their help its out-patient surgical and maternity departments could scarcely exist. And still further, and without any doubt, through the medium of the school, the hospital diffuses its benefits far beyond the range of its in-patient and out-patient departments. Wherever a St. Thomas's man is to be found, whether amid Canadian snows, or Indian jungle, or Australian bush, voyaging on the sea, or practising in some secluded English village, there does the munificence of the founders and governors of St. Thomas's reap fresh and precious fruits. Remarking of the present being the last introductory lecture to be given at the temporary hospital, Dr. Gervis took a retrospect of the changes that had occurred in the school during the seven years they had spent at the Surrey Gardens, and concluded as follows:—We trust that long before the dawn of another October we shall have left these temporary buildings, and entered upon occupation of others whose erection will rank among the most remarkable events of the present reign. Transferred from the south side of London Bridge to the south side of Westminster, rivalling in beauty the opposite Palace of the legislature, and in interest its nearer neighbour of Lambeth, long may St. Thomas's flourish, the pride of its governors, and staff, and school, and a perennial fountain of beneficence for the suffering poor of this realm! May it be the anxious endeavour of her present sons that the prosperity of their commonwealth suffer no less in their hands; but that, as the building of the new St. Thomas's far eclipses in splendour the building of the old, so shall its present school perpetuate and outshine the bright glories of former days.

GUY'S HOSPITAL SCHOOL OF MEDICINE.

Abstract of address delivered on Saturday, October 1st, by CHARLES BADER, M.R.C.S., Lecturer on Diseases of the Eye to the Hospital.

In prefacing his remarks, the lecturer said:—Before offering suggestions as to the mode of passing through your medical career, allow me to say a few words about Guy's Hospital itself. The hospital in a few months will have the largest number of beds among London hospitals. Though too much material may become a disadvantage to the student, and one case well observed be of more use than any number of the same kind of cases carelessly looked into, yet numerous cases simultaneously present in a hospital offer great advantages. The teacher has a choice, he can select the case which presents most of the characteristics of a disease. The student, in a short time, not only sees the chief features of a particular disease, but, like the botanist, among a large number of plants of the same species and in different stages of development, he acquires a rapid and thorough knowledge of the life and history of a disease; the patients, as I have often seen in the large Vienna hospital, find it a great relief to have fellow-sufferers who ward off the inconvenience caused by eager students; we sometimes had to forsake the pleasure of examining a case of aneurism of the aorta, merely because the patient had already been percussed, turned about, &c., by numerous fellow students. Guy's Hospital is not situated in a fashionable part of London; fever and accidents are its usual neighbours. It is surrounded by a numerous hard-working population. The medical student at once and on a large scale meets the harshest features of his work. Years before I had the good fortune of being appointed to the hospital I made it my daily pleasure to visit its pathological museum. I have seen many museums in this and other countries, but have found none superior to Guy's, and, as regards diseases of the arteries, none is equal. Those who enter the medical profession are, I hope, aware that no other profession requires a larger number of general accomplishments. To be thoroughly familiar with the subjects of surgery, midwifery, and medicine before entering private practice, is a self understood thing; but to enter the medical profession with the principles and manners of a gentleman, to have received an excellent general education, to be a good linguist, draughtsman, &c., to be in excellent health, able to share in and fond of athletic sports, are details, all of which are almost as important to success in the medical career as the professional knowledge. Instances of excellence as a linguist, as a Greek scholar, as a draughtsman having secured a medical man's success in life are of frequent occurrence. The amount of knowledge required of the student by our examining bodies as test of his proficiency in medical science is a very moderate one, and should in the fullest sense be complied with. The new Guy's man should study the geography of his hospital. He should visit the wards, the laboratories, the museum, the bath-rooms, kitchen, ventilating apparatus, &c.; the sight of the resources, size, and scientific treasures of his future *Alma Mater* will thus become a source of encouragement. The pupil should carefully impress upon his mind—first, that within a few months he will have forgotten a large portion of the book reading, chemical formulæ, &., required for the examination. To provide for this he should possess the very best books with which to make up this loss, if necessary, and should also connect himself with some one at the hospital who may keep him informed of any important work; secondly, he should not fail to visit Guy's whenever occasion presents itself, and go round the wards and continually keep up an intercourse with some of the medical

men of his school, so that if any good theory or new treatment of importance should present itself he may have the advantage of early information. No one whose means at all permit it should leave Guy's without having frequented other hospitals; for this purpose three or six months should be set apart. Hospitals for diseases of the chest, eye, ear, skin, teeth, throat, urinary organs, fistula, and especially for children, are the places to visit. The liberal character of the medical staff of those special hospitals has, in London, at least, always shown itself by the readiness with which permission to be present and to learn was granted. It would be an excellent thing, he said, if a fund existed, out of which those with insufficient means might be assisted towards the tour of several months in other countries. The contact with more accomplished fellow students necessarily raises the desire of improving one's own faculties.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.

Introductory Address, delivered on Monday, October 3rd, by John Wood, F.R.C.S, Professor of Surgery, Surgeon to King's College Hospital, Examiner in Anatomy at the University of London.

After making the melancholy announcement of the recent death of Dr. W. Allen Miller, and paying a brief tribute to his memory, Professor Wood alluded to the objects of an introductory address, and to the changes in the Staff of the College, which resulted in his occupying his present position, then proceeded to reflect upon the alterations which each year brought about in the principles and practice of the medical art, notifying the direction in which these modifications are now chiefly progressing, and vindicating the Profession from the imputation of differences of opinion among its members, which it only shared in common with most others, dealing more with probabilities than certainties. He advocated a patient accumulation of scientific and medical facts, arranged upon the basis of the hypothesis most in accordance with the present state of knowledge, and acted upon with a provisional and qualified assent, not pushed to extremes, and waiting for that more perfect light which is sure to arise from a just comparison of the differences which the progress of knowledge in every branch will diminish, and finally cause to disappear. He then proceeded to welcome the new comers to the study of medicine, and said—

"Amid the melancholy impressions made by the hideous spectacle now presented by the chief nations of Continental Europe, ravaged and made desolate by the most frightful war that has ever raged in modern times, applying the improvements of our boasted civilization, not in the practice of the humane maxims of the Saviour, by whose name it is called, but in the enormous range, deadly precision, and scientific butchery of its engines of destruction. It cannot but be a satisfaction to you that you are this day enlisting into a corps which is not armed with the murderous 'chassepot' or the death-dealing 'mitrailleuse,' but with the pain-assuaging chloroform and the comforting bandage, with the gentle hand and the sympathising heart, helpful alike to both friend and foe, and tending those whom the fiendish passion for military glory has laid prostrate in the ruins of a late smiling land. You are as it were, binding on your arms, and I hope, imprinting upon your hearts that glorious emblem of triumph even in death, of comfort even in despair, of the most touching compassion in pain and distress, of Almighty help in time of trouble—the red cross, more ennobled now in its saving work in the rear of armies, than when raised on high in the van of battle against the infidel."

The lecturer then sketched briefly the facilities afforded by the Institution and its staff for the prosecution of scientific and medical studies, the arrangements for study and practical work required by the examining bodies, and mentioned that in accordance with the feeling prevalent among the members of the Medical Teachers' Association, a system of marking attendance in the wards of the hospital had been carried out with success during last summer. He did not agree with those who considered that it would be advisable to abolish all schedules and certificates of attendance, and to trust entirely to yearly recurring pass examinations, which could only imperfectly test practical acquirements in large numbers of candidates. Such a course would inevitably lead in the majority of cases to the postponement of serious work to within a few months of the examination, and a more common resort to the practice of grinding. He then described what he considered to be the chief use of lectures—viz., to guide the student through the difficulties of his subject, the multitude of its details, and of the books written about them, and to strike and keep up the key note of the application of true scientific principles to all the variations which claimed their attention. In a practical art, like surgery for example, the firm implantation of simple principles were of great importance to enable the surgeon under the most adverse circumstances, such as a railway catastrophe or a battle, to benefit his patients by the scientific application of makeshifts, where the ordinary apparatus is not at hand.

He condemned the manner in which charpie was used as stuffing for wounds in Continental surgery, maintaining that thus employed it became a means of contagion, and that the simpler, less painful, and more cleanly ways of dressing in vogue in our own hospitals were preferable. He thought that the best use that charpie could be applied to was a material for pads in simple fractures, and as sponges first dipped into a disinfecting fluid, and burnt after being once used, and that, even for these purposes, tow was preferable. He compared the requirements of a good surgeon with those of a good general, especially in respect to foresight and provision for eventualities, the qualities of watchfulness, coolness, courage, and rapidity of conception and execution being valuable in both, with the addition in the surgeon of skill in manipulation with his own hands in carrying out his own conceptions, while the objects of each were very different—one being to destroy life and the other to save it. The lecturer then alluded to the various tendencies to error which he had observed in the course of his career as a teacher among medical students, congratulating his audience upon the immense improvement in the standard of preliminary education which had been effected, and the better prepared and more prolific nature of the soil for the cultivation of scientific and medical subjects which had thence resulted. He urged that the practice of the Art of Diagnostic and Operative Surgery, could only be rightly founded upon a familiar acquaintance with the structures of the human body, and that to work perseveringly at the dead subject, to observe attentively is the only way to remember distinctively and usefully in Anatomy.

In the scarcity of subjects for dissection, which unhappily prevails, it was important to make the utmost possible use of them, in cultivating the art of detecting minute differences.

The lecturer advocated the earnest study of science as a valuable preparation, and training for medical pursuits, and illustrated its direct practical bearings by allusion to the discoveries of the minute living beings which were proved to be the cause of infectious diseases among the silkworms and other lower animals. He then alluded to the opportunities afforded by the hospital, to all the students, to study disease by actual experience of its effects and treatment, and said that, now-a-days, it is not sufficient to *walk* the hospital, but that the student must *work* the hospital with zeal, industry, and perseverance, in order to pass the portals of the examining bodies, who were becoming under the pressure of public opinion more and more practical in their examinations. To aid him to this end, numerous and regular examinations of a practical character, will be carried out in the various classes. These enable a man to compare his progress with that of others undergoing the same training, and were a guard against the imperfection of half-knowledge. And he concluded by warning his younger hearers against the temtations, which beset in London life the path of the young man void of understanding.

FOREIGN MEDICAL LITERATURE.

ALTERATION IN THE URINE FROM THE USE OF CARBOLIC ACID.*

By J. A. Waldenstrom.

Although this remedy has for a long time been used at the Academical Hospital in all forms of suppuration, with a view to checking decomposition of the pus, in three cases only did the urine exhibit any change which could be ascribed to the action of the carbolic acid. The first patient came in with a gangrenous phlegmon in the entire of the right leg. The largest portion of the skin and subcutaneous areolar tissue had sloughed away, so that it was possible to see the soleus muscle almost from its origin to its insertion. To arrest decomposition of the pus, the diseased bone inside the moist warm dressing was enveloped with a piece of lint dipped in the ordinary carbolic acid oil. In consequence of the nature of the affection, and of the patient's advanced age, the prognosis was very bad, and when, after the lapse of eight days, simultaneously with the complete separation of the dead areolar tissue, the urine assumed a dark-red colour, the case was regarded as hopeless. It was reasonable to suppose that the change in colour had its origin in a resolution of the blood, but, notwithstanding the employment of all the chemical reagents, its presence could not be detected in the urine, which was clear and of a strongly acid reaction. On Professor Almén, who kept the urine for closer examination, informing me that it contained carbolic acid in large quantity, I intermitted the use of the solution of the acid in question for a day, when the urine resumed its normal appearance, but as soon as the carbolic acid was again employed, the dark red colour returned. The advantage of employing carbolic acid (for preventing decomposition of the pus, and so the occurrence of septicæmia), and the possible injury from it (in producing a nephritis) made me doubtful whether I should desist from the use of it, or not. However, it was tried for some days longer, but the pieces of lint were first wrung out in a dry towel before they were laid upon the sore, and as soon as this precautionary measure was adopted, the urine preserved its normal colour.

The second patient resembled the one just spoken of in every particular, not only as regarded the seat of the complaint and its extent, but also in respect to the behaviour of the urine in relation to the greater or less quantity of carbolic acid which was used in the dressing. The third case was a middle-aged woman with a very extensive periostitis in the right thigh. The pus that escaped on incision was thin, blood-coloured, and easily underwent decomposition. The suppuration in the large cavity was profuse and of a fœtid character. With a view to check decomposition of the pus, as much as two tea-spoonfuls of a solution in oil of the acid was one day injected into the cavity, the latter having been previously rinsed out with water containing carbolic acid. The consequence was, that next day the urine possessed a tarry colour. Some days later, when the urine had regained its usual appearance, the same injection was repeated with a precisely similar result. The urine was then more closely examined and was found to contain both albumen and the colouring matter of the blood. The latter had already disappeared next day, but the albumen continued, although in small quantity, for a few days. Death occurred as a consequence of septicæmia. A similar transitory presence of albumen in the urine was also observed in a patient who used carbolic acid internally for a syphilitic cutaneous eruption.

From what has been stated we see then that carbolic acid is not as harmless as it is often represented to be. Separated by the kidneys, it acts as an irritant on these organs and may give occasion either to an hyperæmia alone, or to a parenchymatous inflammation, which is not an unimportant complication of the other affections, even if they are not so serious. Neumann's investigations on the action of carbolic acid on dogs poisoned therewith, also show that a considerable fatty degeneration in combination with a molecular breaking-up of the cells of the liver, hyperæmia of the kidneys with a turbidity and separation of the epithelium in the urinary passages are the changes constantly met with on *post-mortem* examination.*

This obliges us to take the greatest precautions in the use, whether internal or external, of carbolic acid, and frequently to examine the urine in order to be able instantly to withhold it on the occurrence of a state of renal irritation. In solution in oil, too, carbolic acid appears to be more readily absorbed than in an aqueous solution, so that we should, in affections such as the two first brought forward, where the acid comes into direct contact with a large granulating surface, prefer the latter form to the former in using it; unless it be made weaker than usually employed (one part in six to eight.)

The cause of this altered colour of the urine, which is met with only in the external use of the remedy, we do not know with certainty, but it probably depends on the presence of some unknown oxidised products of carbolic acid. It may be assumed that this oxidation takes place prior to the absorption of the acid, because, otherwise, we should find the alteration in colour of the urine in cases of its internal use also.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the Medical Press.)

No. VII.

CROYDON SEWAGE FARM.

The population of Croydon is about 50,000, and the water supply, which is constant, amounts to about forty-nine gallons a head. The sewage varies in quantity, according to the state of the weather, from 3,000,000 to 5,000,000 gallons a day, and it flows in two directions—namely, to the Beddington farm, which receives the largest proportion of it, and to the Norwood farm.

The *Beddington Farm* is a little to the west of the town, and about a mile from the Town Hall. It consists of 382 acres of very porous soil upon a deep bed of gravel, and of these about 270 acres are under irrigation by means of open carriers. The sewage, which amounts to about 2,000,000 gallons a day in dry weather, and to more than double that quantity in wet weather, flows by gravitation to the straining tanks, where a portion of the solid matters are detained and removed from it. It then runs through open irrigation channels upon the land, about thirty or forty acres being used at a time for three days, and the crop is chiefly Rye grass, with a little permanent grass, and water cresses are cultivated in the effluent streams. Mangold wurzel and other crops have been tried, but without sufficient success to encourage a repetition of them, except for purely experimental purposes.

The land is at all times in a sodden and offensive condition, and according to the evidence of Mr. Creasy, the surgeon of the neighbouring orphan asylum, who practises largely in the district, and of Mr. Smee, the eminent surgeon and fellow of the Royal Society, who has a garden

in the locality, the smell is sometimes quite sickening. Mr. Creasy, indeed, states that typhoid fever is nearly always present in the houses about the farm, and that all diseases assume a typhoid character, so that Medical men speak of the patient as having a sewage tongue.

Samples of sewage were taken from the farm, as well as samples of outfall water, and the following are the results of the analysis of them :—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	27·67	27·17
Chloride of sodium . .	—	—
Organic matter . . .	2·20	0·75
Ammonia	2·000	0·120
Do. organic . .	0·240	0·015
Nitrogen as nitrates, &c. .	0·000	0·349
Oxygen required to oxydise	0.432	0·242
Matters in suspension . .	10·16	0·00
Organic matter . . .	4·12	0·00
Mineral ditto . . .	6·04	0·00

From which it is evident that the sewage is very weak from dilution with subsoil water, and that it is sufficiently purified by the soil to be admissible into a running stream. It would seem, however, from the Report of the Rivers' Pollution Commission (p. 88), that during frost the purification of the sewage is much impaired, especially when the sewage is strong. It must also be stated that the whole of the subsoil water of the locality is so tainted as to be unfit for drinking purposes, and that every well is polluted ; in fact, according to the analytical inquiries of Dr. Frankland, as stated by Dr. Carpenter, the chalk well in Croydon, from which the water supply for the town is obtained, is charged to a large extent with nitrates, and the other oxydised products of sewage.

The *Norwood Sewage Farm*, which receives the other outfall sewage, is situated at South Norwood, a little beyond the parish boundary of Croydon. It consists of thirty-seven acres of stiff clay land, to which about twenty-four acres of additional land of the same character are about to be added. The sewage amounts to about 300,000 gallons a day, and it is furnished by about 5,000 persons. As in the last case, the sewage flows to the farm by gravitation, and after being strained, to separate the coarser solid matters, it is run upon the ground by open carriers, and where it is likely to be very offensive, by partly covered drain-pipes. The ground is chiefly laid out with Italian rye grass, although a few mangolds and potatoes have been grown by way of experiment, but the success of the experiment does not appear to be encouraging.

As might be expected, the ground, which is an impervious clay, is always in a very noisome condition, and the sewage is not sufficiently well purified, except during the time of active vegetation, to be admissible into a running stream ; in fact, there are great complaints of the stench of the sewage, and of the effluvium from the irrigated ground, by those who reside in the neighbourhood ; and the Rivers' Pollution Commissioners say in their report (p. 86), that during frost the purification of the sewage is not at all satisfactory, for they remark that, on two occasions, when "the frost was by no means severe, yet the organic nitrogen rose from 0·098 to 0·419 per 100,000 parts of effluent water, showing that the removal of offensive nitrogenous organic matter was partially arrested, and indicating that during a severe winter the purification of sewage upon a non-absorptive clay soil may be seriously interfered with," and on some other occasions, when the effluent water was "exceptionally impure," they think it arose from unpurified sewage gaining access to the outfall drains through cracks in the soil. These, in fact, are just the difficulties which stand in the way of the purification of sewage, whenever it is distributed upon impervious clay soils, and soils that are liable to crack in dry weather.

The samples of raw sewage and of effluent water which were taken and analysed had the following composition :—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	41·00	58·19
Chloride of sodium . .	—	—
Organic matter . . .	3·49	4·00
Ammonia	2·000	0·320
Do. organic . .	0·320	0·040
Nitrogen as nitrates, &c. .	0·556	0·601
Oxygen required to oxydise.	0·916	0 824
Matters in suspension . .	11·01	1·98
Organic matter . . .	6·03	0·18
Mineral ditto . . .	4·98	0 80

In this case, as in the faulty cases referred to by the Rivers' Pollution Commissioners, the effluent water was in a very unsatisfactory condition, and so it has been on other occasions when we have examined it.

As regards the commercial success of these farms, it would seem that until recently the farm at Beddington has been let to Mr. Marriage for £5 an acre, the local Board paying a rent of £4 an acre, so that the return to the Board has been £1 an acre for the sewage, and for the cost of supplying it, and for the outlay which they have encountered in preparing the ground—the profit, therefore, considering all things, cannot be much, if there be any ; and on attempting to raise the rent of the farm, the tenant has declined to continue in it, and attempts are now being made to form a joint-stock company to work it. It is, however, remarkable, that those who have been most prominent in expressing their opinions of the value of the undertaking, are evidently very disinclined to enter upon it commercially, and how it will end we are unable to say.

At Norwood the rent paid by the local Board is £10 per acre for the new land which they have taken, and £400 per annum for the thirty-seven acres already under irrigation, and the wages and general expenses, exclusive of the interest of money for laying out the land, and for wages of the surveyor, are about £300 a year, and the returns for the crops sold are about £750 a year ; but the profits depend, as elsewhere, upon the very precarious demand for rye grass, which must be sold when it is ready to cut, let the price be what it may, or it will rot upon the ground ; and hence the price of it ranges from a shilling to threepence a rod of six square feet. Anything which disturbs the demand, as the cattle plague, for instance, or a plentiful crop of hay, reduces the value of the grass to a nominal sum ; but of this we shall have more to say in our concluding remarks, when we review the whole of the facts of the subject and generalize upon them.

Registered for Transmission Abroad.

THE

MEDICAL PRESS AND CIRCULAR

Is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Stamped, 6d.

Post Free to Annual Subscribers £1 2 6
,, If Paid in Advance 1 1 8

*** Post-office Orders and Cheques to be drawn in favour of
A. A. Tindall, 20, King William-street, Strand, London.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 5, 1870.

REDUCTION IN THE SUBSCRIPTION OF OUR JOURNAL.

THE NEW POSTAL REGULATIONS.

The course which the Medical Press and Circular shall pursue in reference to the new postal arrangements has been a subject of anxious consideration with us. On the one hand we have felt bound to give our subscribers the entire benefit of the reduction in our expenditure, and the question has been only in what way that could best be done. On the other hand, the postal authorities interposed so many disabilities and obstructions to the carrying out of our intention that we have found it difficult to do so. In fact, the Postal Act appears to have been carefully framed to prevent the introduction of improvements in such periodicals as the Medical Press and Circular, and to confine the benefits of the halfpenny postage to ordinary newspapers, and we have been obliged, therefore, to submit to the penalty imposed by the Post Office.

It is right that our subscribers should be aware of the exact circumstances. Our expenditure is reduced by one farthing per copy, or 1s. 1d. for each annual subscriber. We have felt that the remission of the sum would be insignificant, and would make our subscription accounts complicated in the working, and we have resolved, therefore, to reduce the rate for advanced payment with the new year to £1, and thus add one-half more to the *bonus* which the postal authorities offer our readers.

We have said that the postal authorities have desired to prevent journals like ours from availing themselves of the new arrangements, and they have attempted to do so by enacting that no periodical shall pass for the halfpenny which is stitched. While we feel that it is a narrow-minded and illiberal policy in a professedly Liberal Government to throw difficulties in the way of publishers making their periodicals as perfect as possible, we are compelled to obey, and in future our journal will be delivered carefully cut, but not stitched. It likewise deprives us of the privilege of re-transmission.

The Medical Press and Circular will in future be the cheapest medical journal in the United Kingdom, and we pledge ourselves, that if our efforts can avail, its value as a professional and scientific recorder shall increase as its price decreases. As the success of any publication depends primarily upon the efforts of its subscribers to obtain additional supporters amongst friends at home or at a distance, we appeal to those who know the independence and impartiality of the conductors of this Journal to further extend its influence and promote the best interests of our common profession.

SANITARY PROGRESS.

The Health Department of the Social Science Association is that in which medical men naturally take the most interest; and the address of Mr. Rawlinson, as President of the Department, went over some of the chief points in the progress made of late years. The President of the Royal Sanitary Commission, Sir C. Adderley, was present on the occasion, and announced that the report would soon appear, so that legislation might be effected next year. Since 1848 plenty of legislation has taken place, and it would almost appear that the great want is rather consolidation and explanation than further laws. A paper was read by Mr. Michael advocating a codification of the existing sanitary laws as a basis for further legislation, and this proposal will commend itself to many minds. At the same time we require an authority in which the country would have confidence, to direct and control, and to which all would look for guidance. In fact, we need a Ministry of Health which should deliver us from the several conflicting and incompetent powers that at present exist. As to the many local Boards of Health that exist, it is to be lamented that they do not comprise, as a rule, the local intelligence on sanitary matters, nor do they even represent it. It was clearly shown at the Congress that we have neither simplicity in the law nor efficiency in its action, and any scheme that would give us these would prove of great value. Commissions we have had over and over again, and desultory legislation has landed us in a quagmire. How are we to get out of it? The discussion that has taken place will be useful in educating the country as to the necessity of studying these questions. We commend to all the concluding paragraph of Mr. Rawlinson's address:—

"Sanitary Science, before it can be of practical use, must be learned by statesmen. The strength of a nation is in its health; and where there is the healthiest community, there bodily purity and morals will have the greatest development. Empires, monarchies, and republics have this lesson to learn. In the cities of the republican States of North America, the worst sanitary defects of the worst cities of Europe are being repeated. The sanitary engineer of the future will know nothing of 'refuse matter' other than as an useful product, which, properly applied to the soil, will add to the wealth of the community. The aim and end of statesmanship ought to be to ensure to every individual born in the State means of health and of morality. Each Englishman's home should not only be his castle, but his hospital. Charity will not then degrade, but will elevate; and that alone will be true charity which assists the poor to assist themselves, and so live independent of almsbegging and almsgiving. We are now proud of our charities—of our public hospitals, which cost £1,000 per bed, *plus* the additional expenses of administration, in which hospital-beds sick men are treated at a money rate three times greater than the wages they could ever earn when in health. 'Our charitable institutions are the glory of our land; but happy will that State be which neither possesses nor needs such form of glory."

EDUCATION IN MENTAL DISEASES.

THE *Pall Mall Gazette* has devoted well-merited attention to existing faults and the English Lunacy system, and in a recent issue it proceeds to argue that those faults are in a great degree the result of deficiencies of medical education in mental disease. It sets forth certain suggestions, the gist of which is that education in lunacy should be enforced in future by the introduction of the subject into licensing examinations, and by the devotion of certain portions of hospitals to mental diseases.

This line of argument opens up an important question of medical education—whether there be any subject in medicine which should be regarded as a speciality to be learned only by persons devoting themselves to its practice, or whether, on the other hand, a duly qualified surgeon should be assumed to be capable of practising every department of medicine and surgery without distinction. Now, it seems to us that, however undesirable it may be to establish partition walls between different branches of medicine, nevertheless, there are certain collateral branches of medicine which ought to be looked upon (as indeed they are practically) as specialities—not necessarily part of a practitioner's education. Lunacy appears to be a case strictly in point, and we therefore hold that medical students should not be compelled to acquaint themselves with any of its details which lie outside a medical circle. Firstly, it is a subject for the study of which a lifetime is too little, and of which no general practitioner could be expected to have any real remedy. Secondly, cases of lunacy requiring medical treatment are such an unusual event in the life of a medical practitioner that labour spent in acquiring a knowledge of the subject would be a very bad investment. Thirdly, the methods of obtaining experience in disease in hospitals are inapplicable to the study of lunacy, and if a student were thoroughly versed in every form of lunacy which could be kept or treated in hospital, he could still know nothing of the subject as a whole.

It is a very mistaken policy, we think, to attempt to take such subjects out of the hands of specialists. It is impossible to do so, because the money value of occasional cases will not repay the labour. A little knowledge of specialities is a very dangerous thing, and a practitioner who repudiates responsibility the moment he finds himself out of his depth is a much more reliable doctor than the versatile genius who is encouraged to believe that he has been taught, and is capable of treating all diseases.

Working practitioners should, in our opinion, be thorough masters of everyday surgery, and the less they think about lunacy, ophthalmic surgery, and other specialities, the better for themselves, their patients, and their profession.

IRISH MEDICAL CHARITIES.

THE scandalous abuse of the Medical Charities of Ireland by or on behalf of persons who are in no way entitled to the benefits of their operation, is a matter concerning which every Poor-law Medical Officer in Ireland is able personally to testify. It is, however, seldom that a guardian thinks it worth while to enter any protest against the perpetration of repeated instances of injustice both to the ratepayers and the doctor, and we are gratified to see that Mr. Shee, of Clonmel, has not hesitated to expose the abuse of the Medical Charities of his Union in this way.

At the last meeting of the Board he called the attention of the Board to the indiscriminate manner in which visiting tickets were granted by members of dispensary committees within the union, and the hardship which such a mode of proceeding entailed on the doctors. He alluded to instances which came under his notice where parties well able to walk about and to travel to the dispensary obtained tickets from members of the dispensary committees to have doctors to visit them. On one occasion a doctor was brought a distance of nine miles to see a woman whom he had attended six weeks previously at her confinement: on arriving at the place he found his patient digging potatoes, and on questioning her concerning the necessity she had for having him visit her, she told him she wanted him to come out to get her child registered. He did not want to have the doctors too carefully shielded from performing their duties, but he thought that members of dispensary committees ought to exercise discrimination in granting visiting tickets, as there were very many instances occurring where doctors were sent a journey of perhaps eighteen miles on errands just as frivolous as the one to which he alluded.

The members present all concurred with Mr. Shee in the justness of his remarks, and it was decided upon to have the opinion of the board on the subject in question represented to the different dispensary committees.

Few medical officers, we regret to say, can calculate on protection from their guardians, and any system which gives scope for such abuses, and makes it necessary for guardians to interfere, obviously requires reform. Under existing arrangements the medical man is practically defenceless. He may have certain reasons to know that the patient is well able to pay, or well enough to be brought to the dispensary, and yet he must obey the red ticket, and continue to attend until the termination of the case. The regulations confer upon him the valuable privilege of applying to have the ticket cancelled by his committee at its next meeting. Probably no meeting takes place for a couple of months, before the lapse of which the patient is either cured or dead. Probably the committee may be inclined to stand by their co-committee man who gave the ticket, and may refuse to cancel it. If they are so complaisant as to do so, the contumacious member may issue another ticket before the meeting has broken up, and the doctor *must* attend on it as if nothing had been done. One of hundreds of instances of this abuse has come to our knowledge within a few days. The clergyman of a suburban village issues a red ticket to which the medical officer immediately attends. On reaching the house he discovers his patient is the child of a well-to-do beerhouse keeper, whose wife informs him that she never had a dispensary doctor inside her door before—that she had not asked for medical charity at all, but merely accepted it at the solicitation of the clergyman. The medical officer hints to his clerical friend that a beerhouse proprietor who had always paid for medical advice was hardly a pauper within the meaning of the law, and suggests courteously a little discrimination as to the recipients of relief. The attendance on the child has hardly expired when another red ticket comes from the same clergyman for the wife of the same person. The medical officer attends and prescribes, but the same night, the patient being in pain, thinks it too far to send a messenger about one mile for the doctor, but calls in a nearer practitioner, whom she properly pays. The conclusion is obvious. The woman felt her unfitness for charitable relief—was ready to pay until Lord Bountiful interferes to make her his *protegé* at the expense of the doctor—and thinks so little of the expense, that she actually does pay another practitioner sooner than send a mile for gratis help.

MEDICINE AND PHILOSOPHY.

THE addition of a new section of Psychology to the annual gathering of the British Medical Association, has been adverted to by one of our contemporaries, as a sign that the study of mental science is about to be recognised as of importance in the medical art. It is, truly, high time that this idea were carried out, since in the very country where the illustrious physician Locke did so much to rescue the study of metaphysics from the dreams of dogmatists of all kinds, there has of late years, been quite a deplorable ignorance of ought connected with theories of the mind, among the rank and file, and even the captains of our medical faculty. It has been, indeed,

the fashion of late years all through England, especially, to decry the study of what is called philosophy, as leading to no useful result. The consequence of which has, of course, been, that for more than a century, perhaps, England has produced no philosopher worthy of the name ; and that his genius has entirely lain in the practical departments of life. Great engineers, and great surgeons, great practical men of all kinds she has produced in scores ; but to Scotland, perhaps, alone of the departments of the British Islands has been until quite recently, left the study of those parts of human knowledge which were disdained by Oxford, Cambridge, Dublin, or Durham.

Mr. Lowe, indeed, has made a very true observation only a few days ago at Elgin, that the Scotch people know the value of education, which he truly adds is more than the English people do. He merely, we opine, pointed to the fact that philosophy has been so neglected in the latter country, that there is at present no clear idea before the mind of the majority of its inhabitants, as to what the aim of human existence ought to be ; and this is true also for France. In that country, the dreams of Cousin and his predecessors, have left the majority of Frenchmen without any idea of what constitutes truth : or, for instance, what ought to be the morality of a state or an individual. It is such want of philosophy, that has, in all probability, sent the French rudderless into the midst of this terrible war. Signs of better times are indeed traceable in the recent works on philosophy in France and Germany, by Taine and Büchner : but these works are too recent to have been able to produce any sufficient effect on great nations still embued with the mere sceptical ideas of Kant or Cousin. Fortunately for this country and for its medical art, as well, our illustrious writers of recent days, have almost begun to reign triumphantly over the best intellects among the younger men of the professions of law, medicine, and even, we suspect, of divinity. No medical man, who desires to understand the physicians' art thoroughly, can now afford to be ignorant of the writings of Locke, Hartley, James Mill, John Mill, and Alexander Bain. And many medical men seem to prefer to any of these names that of Herbert Spencer, whose works, indeed, are especially interesting to the naturalist, on account of the painstaking way in which that author has traced the rudiments of mind through the whole scale of animated beings, beginning from the lowliest. Nor must we forget, in our enumerations or workers in this department of thought, Mr. Lewes, who has shown what an amount of goood work can be done by a student, who had, we believe, no professional training in physiology, when he sets himself seriously to the study of that science. We regretted to notice in a respected contemporary, a tendency (we imagine) to disparage the methods followed by the Mills, Grote and Bain in accounting for the way in which ideas arise in the mind. We admit that such observers as Dr. Maudsley and Dr. Laycock have many specific experiences of mental pathology which may sometimes give men valuable insight into the theory of mental states, but, on the whole, we have failed to derive from the perusal of the works of either of these authors anything like the clear ideas which are to be found in the writings of others.

A very able essay on physical ethics has recently been published by a fellow of Brasenose College, Oxford, of the name of Mr. Alfred Barratt, which bids fair to redeem Oxford from the stigma of having become merely an upper school for the teaching of classics and a little mathematics. Here, again, Mr. Barratt has taken the ideas of Locke, Hartley, and the Mills, as his guide, and has produced a most readable work showing, we think, conclusively that physiology must eventually be acknowledged to be the supreme arbiter in all questions of morals. How often must not all instructed persons have felt keenly that at present in medicine as in other arts, there is no common standard of appeal by which the disputes of Moralists may be decided ; no orderly arranged building where each particular induction of experience may be stored in its proper department, but that Morality is little more than a confused agglommeration of facts and maxims from which each may choose according to his whim, and find authority for the gratification of every passing impulse ?

Moral empirics have hitherto proceeded on the same method as some of ourselves in medicine, by arrogating to themselves cures which nature works, and by pronouncing incurable those diseases which they have failed to alleviate, and so both have deceived many. But, as we soon come to doubt the statements of the one class, why should we longer place implicit trust in those of the other ? Why do we refuse to admit a mathematical formula, unless we can see the reason for it, or, in other words, connect it with the fundamental axioms of the science—yet accept a moral maxim, simply because we have been taught it in our youth or seen it asserted in some dogmatic or fashionable treatise ?

" Physics beware of metaphysics," said Newton, and we in like manner might say " Physiology beware of dogmatic Morality." To the medical men of the future we feel convinced, it belongs to lay down the foundation of a system of utilitarian morality. They alone of all mankind are sufficiently acquainted with the details of the human organism to be able to understand all its wants and unexpressed longings ; but we must in the future determine no longer to consider all study of psychology as out of the domain of the physician. Never was there a greater blunder than this. In former days the clergy united the offices of moral teachers and that of physicians. It was an evil hour when these two departments were supposed to be able to be separated. True morality must be based on physiology, and hence we rejoice to think that medical men are beginning again to read the writings of Locke, Hartley, Hume, and Bain. Without doing so we predict that the science of hygiene for instance, will remain a most imperfect one, and that therapeutics and social science must be content to dwell in a period of perpetual infancy. There is no need that it should be so any longer.

Notes on Current Topics.

About the War and Wounded.

The *Times* has published interesting letters from E. Garrett, M.D., and Elizabeth Blackwell, M.D., respecting the sick and wounded. Miss Garrett who, as our readers will remember, took her M.D. at the University of Paris, urges the need of lady nurses and shows how much they can do. She has just returned from the Seat of War and speaks with authority. The American lady M.D., sets forth the great benefits conferred by women on the sick and wounded in her country's civil war, and urges that similar measures should be adopted on the Continent.

*
* *

A Special Correspondent of the *Pall Mall Gazette* related some cruelties of which the Germans were guilty. Four persons took upon themselves to contradict this statement in a letter garbling the correspondent's assertions and thereby drawing upon themselves a severe, but well deserved rebuke from the *Pall Mall*. The individuals were, however, scarcely of sufficient importance for the *Pall Mall* to take notice of them, but it is well that when one person contradicts another it should be understood that between gentlemen such conduct would be looked upon as unpardonable. What a ridiculous thing it is, after all, for any one to be such a partizan, as to be ready to deny what some one asserts he has himself wit-

nessed. Why should our countrymen thus commit themselves as though they were Germans?

***

A very important letter from Sir J. G. T. Sinclair, has been published, describing what he saw at Sedan and other places he has just visited. He is not at all satisfied with the management of the National Society, and we hope his strictures will be taken in good part, for he further offers some very useful suggestions. He speaks well of the Johanniter who have been severely criticised in other quarters. From all we gather it seems clear that there are many persons about who are really little, if any use, to the sick and wounded, but who succeed in travelling and other matters, at a cheaper rate than those who make no pretence. Sir J. G. T. Sinclair also found accumulations of stores and drugs where they were not needed, and dearth in other places. He does not approve of the ambulance being sent out as proposed under Prof. Longmore, for he thinks that there are plenty there which ought to be utilised, and he found that many of the English surgeons had had little or nothing to do since they had been there, as our foreign brethren kept all the best operations in their own hands.

***

The International Field Hospital we lately announced as about to be established under Dr. Thudichum and Mr. Simon, is now in working order, and we have no doubt that it will be a really model institution.

***

An ambulance is going out for 200 on full service scale, fitted up by the Medical Department of the Army, and it will be under the direction of Prof. Longmore than whom none is more fitted for such a duty. There will be 12 surgeons under him, and we hope they will make some valuable contributions to military surgery.

***

Pirigoff, the great Russian Surgeon, has gone to Basle to the International Society there. Virchow, Langenbeck, and others, too, are at work among the wounded, as are many other illustrious foreign surgeons.

***

An Italian ambulance is, we believe, in Paris, but at present, of course, we are not likely to hear much from the beleagured city, Only one or two of our usual French papers have lately come to hand.

***

The regions devastated by the war present the aspect of plague-stricken countries. Everywhere the sick and wounded abound. Sickness is on the increase, and will no doubt, soon exhibit its ascendancy ever the sword. Winter, too, is approaching, and there seems a probability of a winter campaign, which will greatly aggravate this sad state of affairs.

Pork-pies and Sausages.

The season has again returned for a revival in the trade and general consumption of pork-pies and sausages. We should be sorry to injure an important trade carried on in the preparation and sale of these commodities; but as we find our annotations so extensively quoted, we would fain offer a word of warning to the public, because of the unfair and disreputable advantages taken by a certain class of manufacturer. The pork-pies of Melton Mowbray have long enjoyed a well-deserved notoriety, and we believe all coming from that town may be safely consumed without any deleterious consequence resulting; but we have good grounds for stating that, as a rule, the most inferior descriptions of pork are used in making pies and sausages—pork, in truth, that could not be exposed for sale in shops without incurring the risk of seizure and fine. We understand the pig-killers of the north of Ireland are even on the *qui vive* for the entrails of animals wherewith to manufacture sausages, and that these are exported from Belfast to London in large quantities. In some of the provincial districts of England the pork butcher enjoys a similar means of increasing his trade, and they are not over-particular in purchasing a diseased animal to make sausages. It is a rather difficult subject to identify affected meat once minced in the sausage machine and flavoured with sage, but the after consequences not unfrequently reveal, by a train of disagreeable symptoms, with which we are only too familiar, the nature of the pork employed by the manufacturer. We advise our friends to exercise discrimination in the purchase of these luxuries if they wish to guard against parasitic diseases, or save themselves the suffering attendant upon diseased and unwholesome articles of food. Whilst there is one pork butcher to be depended upon, there are ninety-nine who cannot. We recommend, then, the pork to be purchased and the pies to be baked, and the sausages prepared in the house of the consumer, or under the superintendence of some reliable person.

Pseudo-Membranous or Fibrinous Bronchitis.

Under the above titles, Professor Lebert, of Breslau, has published, in the *Deutsches Archiv. für Klinische Medicin*, a very instructive monograph in relation to a form of disease of the bronchi and air-cells of the lung, which has as yet been but imperfectly recognized and studied.

Professor Lebert describes this disease as an acute fibrinous bronchitis, common in childhood and youth, but rare among the aged, and far more common among males than females.

The disease is characterized by severe paroxysmal cough, extreme dyspnœa, and about the fourth or sixth day there is abundant expectoration of fibrinous matter, mixed often with blood. The fibrinous casts and cylinders are best recognised on examination of the sputa under water.

The auscultatory sounds do not present anything specially distinct from those met with in ordinary chronic bronchitis, and the disease runs a course varying from one to three weeks or more.

In three out of twenty-seven cases death occurred from strangulation, but, as a general rule, the prognosis of the disease in its chronic form is favourable.

It should be kept in mind that the chronic form of fibrinous bronchitis may occur as a symptomatic affection during the course of some other complaint, as for instance, syphilis, tuberculosis, emphysema, and fatty disease of the heart.

When closely examined by themselves the true fibrinous casts are found not to contain any of the red blood corpuscles, but to be composed of white blood cells, pus corpuscles, with epithelium coagulated together in a fibrinous exudation.

Sometimes, after a patient has suffered long with this fibrinous bronchitis and great dyspnœa, there comes on an intense paroxysm of cough and copious expectoration, after which the fibrogenetic action ceases and general convalescence sets in.

A real Boulevard.

Cheapside is now luxuriating in a little quiet. A new asphalte paving is being laid down, and even if it is not so durable as blocks of granite, we hope to see the system extend and so to secure some comfort in being relieved from the effects of the jolting when we venture to drive, and the noise when we walk, in our metropolitan thoroughfares. What a treat it is to stroll along the Thames Embankment out of the range of the everlasting dirt that renders London streets the nuisance of even strong nerved people. What must be the sufferings of those who have irritable nerves and are compelled to live in modern Babylon none can tell. How many diseases may be traced to this as one of the evils of town life few can guess. Our brethren should investigate this point lately brought vividly before the present writer.

A Nest for the Thrush.

We believe there are certain localities in London where thrush is always epidemic, and that it is the rule, instead of the exception, for all children at one time or another to be affected by it in some form. In provincial districts the same rule holds good, for it has been observed in those streets wherein sanitary arrangements are defective and cleanliness not attended to, that the children invariably suffer, in most instances, to an aggravated extent, and in no few cases die from thrush. It is greatly to be deplored the apathy of most Boards of Health, for, if sewage and sanitary arrangements were rendered effective, where they are defective, the common occurrence of thrush might be then more directly brought home to the parent. A correspondent writing to us on the "Nest for Thrush" speaks of a street in a provincial town wherein every young child contracts, and is expected to get, thrush. Surely, this is a terrible state of things, for we hold a child should no more have thrush than variola.

Water-tanks and Cisterns.

After the summer drought when the tanks and cisterns become low in their water-mark, we recommend them to be examined, and if need be repaired, but in every instance well and carefully cleansed before being allowed to fill up again with water. This is just the season that mischief is done, and disease induced and propagated by the use of bad water, because the sediment, if not washed out, becomes mingled with every fresh influx of water. A few years ago we knew a very general and most virulent and fatal epidemic of diphtheria, produced at a Coastguard station by the neglect of this essential duty. It was only when the water-tank was drained, thoroughly cleansed, and its interior whitewashed, that the disease began to abate, and that its virulence was checked. This month we had practical experience of a sharp attack of typhoid fever invading several members of a family who used the water from a cistern which was *dry* in the summer, and into which the recently fallen rain was allowed to accumulate for use without its being previously examined, but when this was done, the amount of filth and mud was truly alarming, for no water coming in contact with it could possibly be pure or free from those gases which are the original causes of blood diseases. We read of leaden cisterns which the dry weather of last summer robbed of their water for some weeks, and that after they received a supply and it was used for domestic purposes that most disagreeable symptoms evinced themselves, in fact, that all who consumed water from the cistern suffered from the incipient train of phenomena which usher in lead poisoning. It behoves us, since we presume to cater for the public health, to advise that all tanks and cisterns should be most carefully examined and thoroughly cleansed before the approach of winter. The chief cost will be the deprivation of water for a few days, a trivial circumstance compared to the deleterious consequences that may ensue from filthy and neglected receptacles for the water we drink.

Glitter.

We notice with a sense of the ridiculous the movements of those of our brethren who have taken advantage of the war on the Continent and the present holiday season of making themselves conspicuous by showing themselves at the Seat of War, and writing home communications to the papers with name and qualifications attached in full thereto, with a most microscopic eye for detail, and not alone satisfied with this, they must needs take every opportunity, when safe again on English soil, of questioning the authority and criticising the communications of those engaged doing *real* work who may write home. We don't wish to be unnecessarily severe, but we cannot refrain telling some of our brethren that the most brilliant anemone possesses no perfume, and that the wandering bee who flits about in the moonlight, intoxicates itself on the blossom of the trebizond. A word to the wise is sufficient we hope in abolishing this vulgar glitter.

Cyder Poisoning.

It will be in the recollection of our readers that several well marked cases of lead poisoning traceable to the drinking of cyder occurred last year. It may not prove *mal apropos* if, at the present season, we remind those who manufacture their own cyder of the great care and absolute necessity of guarding against putting the cyder in leaden receptacles, for a most common sense reason. The acid character of the cyder is sure to act upon the lead, and produce accordingly its deleterious influence upon the system of those who may consume it, in proportion to the length of time in which the cyder was in contact with the lead.

One remarkable case occurred last year when a man, who made a large quantity of cyder more than he had vessels to receive it, placed it in a leaden cistern for a time, but all who partook of that from the cistern were seized with unequivocal symptoms of lead poisoning, so that it was condemned for the use of pigs, and even these too, became affected in a marked degree.

Several persons were convicted and fined in London on Saturday last, for refusing to comply with the provisions of the Vaccination Act—the magistrate intimating that in all cases brought before him he will inflict such penalties as the negligence of so useful a provision warrants.

The Late Dr. Augustus Waller.

We regret to announce the death at Geneva, on the 18th September, of Dr. Augustus Waller, F.R.S. Dr. Waller held a high place among those physiologists who have enriched their science by original research. He made many contributions to the physiology of the nervous system, and introduced a new method of investigation applicable to various objects of inquiry, which has tended to advance our knowledge. He twice received the Monthyon Prize of the French Academy of Sciences—first in 1852 for a research, in which he was assisted by Prof. Badge, of Bonn, and again in 1856 for his experiments, showing an important relation between the nutrition of nerve fibres and their connection with nervous centres. He died quite suddenly in a fit of angina pectoris, to which complaint he had been for some time subject. He had recently resided at Geneva. We believe he was one who, in spite of their boast of fairness in elections, the authorities of University College unaccountably passed over.

The Accomplices of Baby-Murder.

One of the baby-torturers is to be hanged, and the other sent to prison for eighteen months. Well and good! but what about the persons who by nod and wink incited them to the murder of the poor babes? When the daily papers have exhausted their virtuous horror against these murderesses, perhaps they will bring forth from beneath the cloak, which has been thrown over them, the infamous women and their paramours, who have consigned, we fear knowingly, their babes to such a fate. Let us be spared the mock indignation which assails the condemned and defenceless agent, while it keeps snugly concealed from observation the fashionable inciter, to the crime for which their servant is about to suffer.

The police must know in many instances who and what are these persons. Let them, at least, have the condemnation of publicity.

Daniel Come to Judgment.

The inevitable working man has effected a lodgment in a body in which our profession is more especially concerned, and in the person of a Mr. Applegarth is selected to deliver judgment on syphilis prevention.

The principle that a "working man" is to be entrusted with medico-scientific investigations because he is a working man, and not a lord or a gentleman, or a professional man, is rather peculiar in its logical bearings.

As the English nation, in the person of Mr. George Odger, has gone to make peace, we are bound to presume that diplomacy is intuitive, and is as much part of a "working man's" economy, as large feet or prominent ears, but we object to science being constituted one of the innate qualifications of the "working man."

We have experience that a lord or an M.P. may, as a committeeman, be a blockhead, but until he shows himself to be so, the *primâ facie* evidence is all on the side of his educational competency. In estimating the committee value of the "working man," the evidence is all the other way, and it appears to be a peculiar policy to ask a man to give an opinion on science, because we know that his pursuits have made it impossible for him to know anything about the subject.

If the Government really meant to find out the truth about syphilis prevention, they would put men of education and observant habits to search for it, and not spouting blacksmiths or political mosquitos.

It has been pointed out to us that in our number for September 7th, we compared the cost of the Dublin and Queen's University qualifications, giving the cost of the former as £99 4s., of the latter as £5.

Our correspondent says :—

"This is a mistake, the cost of the Dublin degree is £5 for the liceat ad exam, and £11 for the degree itself. The £99 4s. is probably the aggregate of fees during the curriculum, and in the Queen's University these would amount to a sum not much short of that mentioned for Dublin."

We quoted the figures from the Parliamentary return.

Pharmaceutical Frauds.

A striking display of the audacity which impunity engenders was made last week by a Mr. Rimmington in the presence of the Pharmaceutical Conference. We have more than once pointed out that the product sold in commerce as citrate of magnesia is an impudent fraud on the consumer—contains universally no citric acid or magnesia whatever, and is not in the slightest degree aperient in its action. Mr. Rimmington not only openly admits the regular practice of this piece of roguery, but lectures the Conference on the proper admixture of tartaric acid, lead, soda, and sugar to make citrate of magnesia. If his remarks had been allowed to pass without repudiation he would have indirectly pledged the Conference to countenance the fraud; but we are pleased to observe he miscalculated the effect of usage on his audience, for many persons very properly protested against the use of what they euphuistically called a "misnomer," and Mr. Summer stated unequivocally that this was not the only misnomer which the Conference ought to denounce.

A resolution expressive of this opinion was proposed, but was received with disfavour by Mr. Greenish, Professor Attfield, and others high in pharmacy, on the ground that "there was no necessity for alteration of name so long as the preparation was only commercial, and never prescribed—if difficulties were thrown in the way of its sale by chemists, grocers would take it off their hands." Should we not have seidlitz powders and soda water brought under similar condemnation? At last the resolution was emasculated and passed.

We are surprised and ashamed at the adoption of such special pleading in defence of an obvious swindle by officials of the Pharmaceutical Society. Without doubt, the consumer, who is not behind the scenes of pharmaceutical "misnomers," is given a cheaper and worse article than that which he buys, and such a practice is a fraud, and all the worse because its perpetration is very frequent. As the lax morality of a money-making Government countenances such white lying, the responsibility of repudiating it is thrown on the Pharmaceutical Society, and we hope it will honestly fulfil the duty.

A Globule-Medical Coalition.

The daily papers inform us that a Congress of Homœopathic Practitioners met last week at Birmingham, in flattering imitation of the British Medical Association. There was, of course, an Address in Medicine, and we

learn that a considerable portion of that effusion was devoted to an endeavour to level the boundary between homœopathy and legitimate medicine. It was elaborately explained, we are told, that the homœopathic law of treatment was only followed where it was applicable, and that other remedies were prescribed when homœopathic remedies were not ascertained to be best. Such an admission issuing from the mouth of the President of the Congress is very significant, for it amounts to nothing less than an abandonment of the principle in which homœopathy has been, hitherto, supposed to consist.

But, on the part of the Profession, we must respectfully decline the fraternisation of homœopathy. If Hannemahn be god let him be god. If billionethy of a grain of medicine be sufficient for the treatment of disease, drachms and ounces must be poisonous, and their administrators criminals. The theories of homœopathy and scientific medicine are wholly inconsistent and incompatible, and he who believes in one cannot have confidence in the other, so we object, *a haute voix*, against a system of practice which provides sips of water and snuffs of flour for hippish old ladies and raking purges and mercurials for people who are really sick.

Is Pharmacy a Science or a Handicraft?

The *Lancet* has published in a recent issue a remarkable editorial essay in condemnation of the "monstrously excessive" charges made for the dispensing of medicines by pharmacists. Without staying to inquire into the reasons which may have led our contemporary to the adoption of this startling line of policy we feel it necessary to combat very strongly the cheapening policy which it advocates. We are not going to maintain high fees, on the ground of the advantage which should accrue to the Profession by "keeping up the price." That principle has suffered enough by the patronage extended by the present Government to trades unions, and it is unnecessary for us to discredit it further by attempting to control in favour of the Profession the simple principle of "buying in the cheapest market and selling in the dearest." The question cannot and ought not to be dealt with by trades-union compulsion, nevertheless it is not, in our opinion, the place of the *Lancet* to inaugurate a cheapening movement, which cannot fail, sooner or later, to reflect from chemists to doctors and surgeons.

The question is *not* what the just cost of the medicines may be as compared to their selling price, for they are only the objects on which the pharmacist exercises the skill for which he is paid, and, therefore, the cost has not very much more to say to the dispenser's fee than the wear and tear of instruments has to the remuneration of the surgeon who uses them, We altogether repudiate the idea that the duties of a pharmacist are, as the *Lancet* says,—"A mechanical thing to be done by a pupil in his second year." If such a statement be correct, what is the meaning of the Pharmacy Act, and the legal requirements for education and examination of pharmaceutical students? It is unfortunately true that the supplying of medicines by medical men has made pharmacy in some respect "a mechanical thing," not, if the system were what it should be, if the selection, analysis, preservation, and composition of medicines were confided solely to pharmacists, there would be an important position for them to occupy as guarantors to the public.

As it is, the general practitioner does not know what the medicine he compounds may be, and the patient has no safety of the purity or efficiency of the physic he takes, simply because the dispensing is done by a person who has neither the time, inclination, or special knowledge to trouble himself with pharmacy.

Believing as we do that there is no natural identity between medicine and pharmacy, and that either science is enough for the study of any one man, we object to the policy of the *Lancet* (of which its last dictum is an expansion) of making medical men into pharmacists, and pharmacists into mere vendors of perfumery and tooth brushes.

The Late Professor Miller, F.R.S.

Our readers will observe that the Introductory Lecture at King's College, delivered on Monday afternoon, and of which we furnish an abstract in another column, opened with the melancholy announcement of the death of this most distinguished professor.

Plague of Flies.

Last week we published an annotation on a swarm of Aphides. This week we find by the following, clipped from a local paper, that the evil still exists :—

"The neighbourhood of Newark was visited on Sunday last with one of the ten plagues of Egypt on a small scale. Throughout the whole of the day the atmosphere was densely crowded with millions of small flies, which almost negatived the idea of taking a stroll out. The town and neighbourhood of Nottingham have suffered from a similar visitation for more than a week."

We believe these insects have had their origin in the turnip fields and cabbage gardens. We learn that the air was literally black with them, and that it was an utter impossibility to walk abroad without swallowing a quantity, producing considerable irritation in the fauces.

Foot and mouth diseases appear to be on the increase still.

The epidemic of fever at Liverpool seems still to increase.

We understand that Mr. Henry Lee, of St. George's Hospital, has resigned the consulting surgeoncy to the Lock Hospital.

Reports from Zanzibar state that cholera had entirely disappeared from that place, but was very prevalent at Mozambique.

Nature states that the *Quarterly Journal of Science* has passed into the hands of Mr. W. Crookes, F.R.S., who will from the present time be sole proprietor and editor.

As a result of the recent grand festival at Birmingham, the funds of the General Hospital are expecting an augmentation of nearly £6,000. This is as it should be.

The next examination for the Society of Apothecaries' Annual Distribution of Prizes in Materia Medica and Pharmaceutical Chemistry will be held on the 19th and 20th of October.

By advices from India, we learn that the new barracks on the double storied system have been productive of great sickness amongst the regiment quartered in them. The buildings are damp and leaky in the extreme.

At the weekly meeting of the West Derby Guardians held on Wednesday, Mr. Bird called attention to an entry in the governor's journal, which stated that he (the governor) hearing a noise in the surgery on Friday night last went there, and found the porter struggling with the dispenser, who was very violent. The matter was brought under the notice of Dr. Reed, the surgeon, who subsequently reported that the dispenser had been partaking freely of the spirits of wine, and was consequently in a "complete state of madness."

SCOTLAND.

Glasgow.—At a meeting of the Faculty of Physicians and Surgeons, held on Monday the 27th, a portrait of Dr. A. Dunlop Anderson, a late much respected President, was presented, and is to be placed in the Hall of the Faculty.

St. Andrews.—At a recent meeting of the town council of this city there was inserted in the minutes the expression of regret for the great loss which the council and city had sustained by the death of Dr. Adamson.

Aberdeen.—Dr. Dyce Davidson has been elected Ophthalmic Surgeon to the Royal Infirmary in room of Dr. Ogston.

Literature.

TREATMENT OF HEPATITIS AND ABSCESS OF THE LIVER WITH CHLORIDE OF AMMONIA.*

This paper of Dr. Stewart is an enlargement of a contribution to the *Lancet* published some months since. He recommends in hepatic attacks "when the acute symptoms have been allayed and suppuration is either threatened or already established, or in the event of the patient having come under observation in the primary acute stage as soon as the symptoms local and general, shall have been abated and diaphoresis fully established that chloride of ammonia should be administered in doses of gr. xx morning and evening." Dr. Stewart ascribes to this remedy powerful diaphoretic and diuretic effects which he considers are seldom noticed, unless when it is administered for hepatic disease. He details several cases where success has followed its exhibition, first an example of well marked acute hepatitis, then three cases of hepatic abscess, and finally, a case observed by Staff Assistant-Surgeon Alexander, of its beneficial use in chronic hepatitis.

Chloride of ammonia is a substance that appears to have gradually fallen out of use in therapeutics, it still bears some reputation on the Continent, and is prescribed occasionally by a few practitioners in our own countries, in cases where others employ iodide of potassium as an alterative, and in chronic diseases, bronchitis, &c., and for dispersing tumours. The present day demands exact observation and rather strict scrutiny before admitting the claims of some old fashioned remedies to be received in the list of active therapeutic agents, but it appears worth while to examine somewhat the grounds on which so many practitioners have, from time to time, considered chloride of ammonia deserving the rank of an energetic and valuable remedy. Should experience sustain Dr. Stewart's expectations of its usefulness in the treatment of hepatic diseases, its restoration to the list of our reliable remedies will be an advantage of considerable importance.

* Treatment of Hepatitis and Abscess of the Liver with Chloride of Ammonia. By Wm. Stewart, M.D., Surgeon 2nd. Bat. 21st Royal N.B. Fusiliers. Rangoon, 1870.

UPON THE THERAPEUTICAL VALUE OF THE SULPHITES IN PHLEGMONOUS ANGINA.*

Dr. Tyrrell, a former pupil and graduate in our Dublin School of Medicine, contributes to the *Pacific Medical and Surgical Journal* for August 1870, an interesting paper on the above practical subject. He states "on reading Dr. Pollis's discovery of the use of the sulphites, published by Dr. de Ricci in the *Dublin Quarterly Journal*, November 1863, I determined to test the matter for myself. Unfortunately at that time no bisulphites were to be had upon the Pacific coast, and it was not until the Spring of 1866 that I was able to procure a pound of the bisulphite of soda. My notebook then informs me that I tried this salt in several cases of scarlet-fever, giving ten to fifteen grains every three or four hours without any well marked advantage over my former treatment by quinine and iron. Again, I find a case of pyæmia in which I gave my patient twenty grains every four hours without mitigating the disease in any respect, this result I rather anticipated as the case was not seen until several of the joints contained pus. I find myself next employing the sulphites in the treatment of some cases of typhoid fever. Still, I was not aware of any striking result that followed, except that they had the power of diminishing the extreme fœtor of the alvine evacuations."

In 1868 an epidemic of a species of influenza prevailed, accompanied by a remarkable frequency of anginose affections, especially acute tonsillitis, terminating in abscess; this induced Dr. Tyrrell to resume the use of the sulphites, pushing them to saturation as we do other alkalies in the treatment of rheumatic fever. It happened that the doctor became his own first patient for this experiment; he took thirty grains of bisulphite of soda in solution every hour, commencing at noon, and by eight next morning almost all trace of the disease had vanished. Some additional cases illustrating the rapid improvement induced by this line of practice are detailed, and in all Dr. Tyrrell mentions about twenty-two cases, of which only a single attack terminated in abscess, and in this the remedy certainly did not receive a fair trial; of the others "not one exceeded forty-eight hours in duration after the commencement of the treatment by the sulphites."

The experimental trials of the same remedy in diphtheria are less satisfactory, two children recovered and one died, and Dr. Tyrrell who is a good practical physician and reliable observer, admits himself that this is too small a number to base any opinion upon as to the value of the sulphites in this disease, though it appeared to possess a power of speedily removing false membrane in the particular attacks recorded.

The results which Dr. Tyrrell has obtained by his method of giving bisulphite of soda in free repeated doses will, we hope, lead to further research on its alleged properties. Unlike some sensational articles of medical intelligence occasionally met with, the paper now noticed is the work of a practical physician, well known to his former teachers in this city as a most industrious and intelligent pupil.

The late Mr. John Abbott, of Halifax, has, by his will, bequeathed the large sum of £60,000 for various public or charitable objects, including the following sums to medical charities:—£2,000 to the Halifax Infirmary; £1,000 to the Bradford Eye Institution; £1,000 to the Bradford Infirmary; £2,000 to the Leeds Infirmary; £1,000 to the Cancer Hospital, Leeds; and £2,000 to the Manchester Infirmary. Mr. Peter Tharel has bequeathed £500 to St. Vincent's Hospital, Dublin.

* Upon the Therapeutical Value of the Sulphites in Phlegmonous Angina. A Paper read before the Sacramento Society for Medical Improvement. By Gerard Geo. Tyrrell, L.R.C.S.I. and K. and Q.C.P.I.

Correspondence.

A HOLIDAY VISIT TO THE NORTH OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Making my annual holiday this autumn I took occasion to visit some of the northern county infirmaries, institutions for which I entertain a high respect, and in which much good surgery has been practised, although not as well known as is desirable. The first I visited was that of co. Down. Placed on an elevated position outside the town of Downpatrick, within a handsomely planted enclosure, the approach excited my expectations to a high pitch, but I was sadly disappointed. The ill-ventilated wards were made more offensive by the close proximity of ill kept bad water-closets, while the bedding and furniture was mean in the extreme. It is astonishing to me that, at a period like the present, when the attention of the ladies of the country is so much drawn to the care of the sick and afflicted, that the ladies of the co. Down do not unite to make the co. Infirmary what it should be, a credit to the county, and to see that the injured tradesman, the reduced farmer or shopkeeper, and the respectable, but afflicted domestic servant, should have a refuge where they might expect the greatest amount of comfort and cleanliness with the highest class of professional attendance. I have not the pleasure of the acquaintance of the surgeon of the co. Down Infirmary, but I saw in the hospital one case which alone stamps him as a surgeon of the highest professional capacity, who would not be out of place in a metropolitan institution. What an advantage to have such a man resident in the locality, and what a pity that he should not have under his care an hospital of the most perfect construction and kept in the most approved style.

I then visited the Londonderry Infirmary, and was most courteously received by the house-surgeon. This is a fairly kept hospital, and though old-fashioned in construction, is capable of being brought to much greater perfection than exists at present. It struck me, however, that the presence of the ladies would add greatly to the comfort of the patients, for, to my eye, the nursing is not of the quality I would desire. Here, too, the medical attendance seems to be of a high standard. Passing on I reached Strabane, and thence walked over to see the Lifford or co. Donegal Infirmary. Not meeting any of the medical men I refrained from examining any of the cases, but the nurse pointed out to me nine which had been operated on with great success, but the hospital is a disgrace to the great county. It is the most ramshackle institution I ever put my foot in, and ought to be replaced by a modern structure. Efforts are being made to have the institution of the county removed from Lifford, which would, in my mind, be a great mistake. There is no other town better placed, for, though not central, the position is such that equal radii drawn from it would spread fan-like to all parts of the county bounds, and it is more easy of access from all parts than any other town within this. Here, again, I appeal to the ladies of the county, and will it be in vain? Large fortunes are drawn from the county, and surely, a little attention to the wants of the distressed would be a gracious return. I next visited the Omagh Infirmary, co. Tyrone. The hospital is not well constructed, and is in the centre of the town, forming part of the street. It is kept in a state of admirable cleanliness, and the furniture is neat and respectable. Few hospitals have turned out more creditable cases of surgery than this, particularly under the present able surgeon, and I take it that it is to his energy that the very admirable state in which I found it is due; yet a new hospital is wanted on a better site, and I would have much preferred seeing a larger assemblage in the town, for the purpose of opening such an institution than assembled the day previous to my visit for opening a Protestant Hall. I am not one to deny the value of the latter institution at a proper time and place, but I much prefer those institutions where suffering is relieved, and the bonds of kindliness formed between men of all creeds and parties. Having to hasten home I visited but one more hospital, *my Alma Mater*, where I passed so many happy days of my youth, the Queen's Co. Infirmary, and proud I felt to stand within its walls again, and to find it kept in the same prominent position, which it has maintained for the last half century, a model of comfort and cleanliness, a source of pride to the county, and I blessed the memory of the worthy man* who gave his time, his care, and his money to its erection, to the worthy men and women who, as governors, governesses, have looked after its state, and to the surgeons past and present who have so well maintained its reputation. *Semper Floreats.*

Your obedient servant,

Portlaw. JAMES MARTIN.

ACUTE RHEUMATISM AND GOUT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In treating acute rheumatism, Dr. Sibson, like Lord John Russell, says "Rest and be thankful" to every joint of the patient.

I don't believe it, and would say in reply, as I have said five thousand times before, that in rheumatism, acute, subacute, or chronic, that rest begets rust, and the joints become stiffened, ankylosed, and probably crippled for life, leaving, perhaps, in after years, merely a bag of bones in deformity, not bare, only shining through a very thin skin, which, if entombed, would relieve the sufferer, but hardly bring the science of medicine up to what I regard to be the proper standard. In treating acute rheumatic fever, in which a single joint, perhaps, at first only aches and is slightly swollen, and is attributed to an ankle sprain,—as in such a case that presented itself to me to-day when I was first called in,—do just as I do. Feel the skin and smell the sweat. Use the litmus to the secretion, and ascertain the preponderance of either lactic or lithic acid, or it may be sebasic acid, by testing skin and kidney. Sp. g. may be left alone, *pro. tem.*, strip the patient from head to foot, place him in bed, and administer a warm water emetic, glass after glass, pint after pint, till the stomach, which will hold at least two quarts, is "quite tight full," as a learned professor of my acquaintance terms it. When a boy, I was told, "what goes up must come down;" when a man, I learnt that, what went down must come up, if given as an emetic, and this I generally see done before my eyes by means of plenty of warm water with a grain or two or more of *very common salt.*

Fill the stomach with simple warm water, tickle the throat, and emesis is almost sure to ensue. If not, add a few grains of *common salt* again, and oh! oh! soon fills the basin with a flood of fluid of various sorts. This simple operation clears and cleanses the stomach, whilst at the same moment it opens the ductus communis choledicus, which lets out the bile, unloads the liver, stimulates the duodenum, and gets the bowels to act of their own accord through their natural purgative, the bile.

This emetic failing, a few grains of ipecac. or zinc will assist.

A brisk purgative follows in the shape of compound jalap and calomel, which soon does its work at the lower part, and the ejecta tells you the course is clear. On receipt of this information from various quarters, the patient is stripped, put into a hot wet blanket or Brady's vapour bath, kept in bed, subjected to the following medication:—

℞. Potassæ bicarb., ℈ij.;
Pot. nit., ʒij.;
Vini. colchici, ʒiij.;
Aq. fout., ʒviij.;
M. fr. mist. cujus capiat, ʒj.;
4tis. horis ex. decoct.

Mordei cyatho.

This goes on till he finishes the bottle, and repeats the blanket sweating every four or six hours during the allotted time. The nitrate is diminished, the bicarbonate is increased, and the colchicum is gradually withdrawn as the motions approach in colour real good pea-soup.

The soup tells me the liver is acting, and that I have the whip and upper hand of my enemy, articular rheumatic fever, and that I need not fear either endocardial or pericardial murmur or whistle; but that on the tenth day, my patient, young or old, provided he is free from serious organic disease, will sit up in his clothes, and enjoy his mutton chop and his bottle of Dublin stout.

Rest and thankfulness means from twenty-three to thirty-three days of bed-riding in acute rheumatism. When I was

* The late Thomas Parnell.

in the Newcastle Infirmary twenty years ago, the average duration was twenty-three days. In the Newcastle Dispensary, when lemon-juice was in vogue, Dr. Humble and the late Dr. Pearce could prove that twenty-one days saw the man, woman, or child about, not on crutches or sticks, but practically and peripatetically cured.

These are naked facts which speak for themselves.

Professor Bennett properly insists on having one hundred and one facts to establish the existence of a single fact in any science ; and with his view I am sure our entire profession accord as regards medicine and surgery.

In times of war we cannot lag,
Yet this, our calling, must not fag.
I am, Sir, yours truly,
JOHN A. BOLTON, M.D.

Leicester, Sept. 6, 1870.

MR. MORGAN ON THE UNITY OF THE SYPHILITIC VIRUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been intensely interested in Mr. Morgan's experiments, which, indeed, only confirm what our friend, Dr. Bœck, showed us in London when he was here, in his inoculations at the Lock Hospital from matter from hard sores, from Christiania "On Syphilitic Women." I trust Mr. Morgan will pursue these most valuable researches. It is, however, remarkable that it is by no means difficult, in the immense majority of cases of syphilitic ulcers in males, to say when they are infecting and when not. I am quite ready to suppose that the vaginal secretion which produced a soft sore on the syphilitic women would have produced a hard sore on most healthy persons.

CHARLES R. DRYSDALE, M.D.

99 Southampton row, W.C., London.

THE FORBIDDEN TOPIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst I agree with you in suppressing a religious controversy in your Journal, which, albeit the only thoroughly independent one I know, is nevertheless a medical publication, will you permit me for the satisfaction of all concerned in the late correspondence, and for Dr. Drysdale's instruction, to send you the following extract from a communication published in separate form by one of your gifted correspondents, "Prudentia." The quotation has no direct reference to religion, or the ministers of religion, but it indisputably proves the accuracy of the statements made by Dr. Waring-Curran in the last impression of your valuable periodical.

"An interesting and important, though difficult and rarely discussed point in physiology, is the relation of the generative apparatus to the moral character, and the degree in which the former is subservient to and regulated by the latter. I think it would be found that it is so to a very great extent—greater perhaps than is usually recognised ; and it is desirable that practical men should pause a while upon a question of this sort, and not hastily commit themselves to opinions which may have much influence upon the well-being and happiness of society. There are no organs so much under the control as those of generation. Their functions are neither directly nor indirectly in the least essential to life, scarcely even to the well-being of the body. Indeed, which is more remarkable and unusual, they are scarcely essential to the maintenance of the structure of the organs themselves in perfect integrity. The functions of the testicle, like those of the mammary gland and the uterus in the female, may be suspended for a long period, possibly for life, and yet its structure may be sound and capable of being roused into activity. In this respect its qualities peculiarly adapt it for subserviency to man's moral nature. Not that it always yields a tame and willing submission : by no means. That stern struggle between the moral and the physical is one of man's greatest trials, and it is some satisfaction to know that if the victory be with the moral, it is not necessarily at the expense of the physical, but a positive good to both is achieved !"

Did the above bear upon religion more than science I should not trouble you or ask to break your rule. Let me express a hope that Drs. Drysdale and Curran may be induced to shake hands over this misunderstanding, and that both may agree to attack and exhaust the subject of *New Questions* opened unto them in your excellent journal, for the object is one and the same—advancement.

Your humble servant,
"CANTHARIDES."

P.S.—Being a French fly, with orange, purple, and green blended together in my wings, and loving priest and parson alike—because I hold it a great cruelty that men should suffer insult or wrong, because by a freak of nature, or through the accident of circumstances, they should happen to be born within the pale of a certain church, or that their infant lips should be tutored to lisp a certain form of prayer in preference to another form—I have a right to address you, lest the Anglo-Saxon should repudiate the friendship of his brother, the Irish, or *vice versâ*, neither of which may ever be.

September 22nd, 1870.

NEW QUESTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I heartily concur in the remarks in your issue for September 21st, in the conclusion of the paragraph (New Questions)—That the fearful condition to which the youth of both sexes reduce themselves, by the schoolboys and girls' filthy habit of masturbation. The disgust which is naturally felt by all considerate persons should certainly not prevent medical men from treating a disordered functional condition so entirely destructive of a "sound mind in a sound healthy body." From some cases which have lately come under my observation, but neglected or overlooked by the doctor treating the patient as consumptive, while the seminal effusion continued, though the actual bad habit may have been discontinued. This should have called for more decided efforts to check the flux. In the case I particularly refer to at present, the medical attendant who had cruized with him the previous year, was again called in during the close of his life at an early age. A few years after his majority he confessed at last, that he was aware of the sexual state of matters, but did not think it of sufficient importance to require treatment, and thus a fine youth of twenty-four was allowed to die from inattention. I do not mean that this was the sole cause of death, but it was so destructive to the healthy condition of the system as to hasten the rapidity of the decline.

I fully concur in your hope, "That a day is coming when nothing in medical art shall be considered *common or unclean*."—Yours, &c.,

F.R.C.P.E.

INTRODUCTORY LECTURES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Most of the introductory lectures will be delivered in the London Schools before the following remarks reach your readers. As I write they, too, are being prepared, not in many instances with the direct object of teaching the future student of medicine more than which hospital and school will produce —the most *récherché* and the greatest lion of an address. But, as upon the commencement of every other session, we shall have the modern Platonist, who quotes Galen, Æsculapius, and Celsus, morals over the theories of Galileo, and is astonished why the discoveries of Harvey and Jenner were not made years before, because of their simplicity. I expect to see a report of the religiously-perfect lecture, with quotations from St. Luke ; extracts from Priestly and Cordorét, with kindly advice to the "Ambitious student in ill-health." Then there will be Dr. Morphia Velvet's observations about the rights of women, and the impracticability and absurdity of admitting Dr. Elizabeth Garratt and Mary Walker into the arena of medicine. He will philosophise over his own successes and ingenious undertakings, while he forgets to inform his audience about the silver spoon, which was born with him, and the *Marinade à la St. Florentin*, upon which his professional distinctions were sustained. Then we get the learned effusion respecting aëriforms, solidiforms, and fluidiforms, and hæmatite and manganese, antimony and gypsum, which, to the verdant pupil, is as valuable and as instructive information as the tragedies of Æschylus, the orations of Isceus, and the speeches of Syrias, delivered in the mother tongue would prove. I had

the satisfaction a few sessions ago of reading—I had not the misfortune of being compelled to listen to—the recital of a very learned introductory discourse, which bore entirely upon botanical subjects, and all pertaining thereto. But "the cypresses of Itchiatuckanee" must have been poor "value" for him who came for the first time into a lecture-theatre, expecting to be instructed in the course he should pursue as a student in learning the details of his Profession with the greatest facility and expedition. I object to those lecturers who assume the authority, and imitate the tone of the parson respecting sage advice. I do not advocate young men being tutored either in religious subjects, on the one hand, by the lecturer, nor, on the other, by the porter where the best beer and tobacco may be procured, as inclination prompts the student to bring to bear his earlier training whether to practise levity or go in for sound sense. He is influenced neither by porter nor lecturer. In the pew of his father's church, words more emphatic and *àpropos* have wafted themselves down to his ears from the pulpit of the preacher. He takes his seat among the throng of youthful, earnest faces for the first time, and expects to be told in simple language what he shall actually do; what subjects he may safely take up and work at; and what he may postpone until further advanced. He wants the mirror to be held up before him, and in clear and distinct language to have reflected and mapped out upon it the path to be followed, and with precision the flowers to be culled; instead of the elevated, sensational, diffusive, and interjectional profundity of aspirants, who aim more at unintelligible flummery, with a spicing of delightful philosophy and metaphysical erudition, than the real lesson which should be simply and emphatically taught—not preached. I am only timid of those long written manuscripts, which hint at everything but assert nothing. I desire to see some representative of one of the schools fearlessly coming forward, who has investigated the subject thoroughly, and who will, *extempore*, teach first principles and rules for early guidance to the men. No reading, no profundity, no metaphysics, say I, at introductory lectures. I stigmatise as vulgar cant ready-made discourses, copies of which are in the printer's hands, or, perhaps, set not only in type, but printed on paper, and circulated, as on a certain occasion last session, before they were read or delivered, for the instruction of those students. Grand excuse to some for fine writing, for "thipped syllabub" and buffoonery, for half a column in the *Times*, and a leading corner in one of the journals.—I am, &c.,

"A Listener."

Gleanings.

The Abuse of the Speculum in America.

The following article from the current number of the *Boston Medical and Surgical Journal*, one of the best conducted organs of the Profession is worthy of attention on this side of the Atlantic:—Our attention has been called by a correspondent to the great frequency with which this instrument is used, often needlessly, and, in far too many cases, in young impressionable females, where only absolute necessity should call for such an investigation. It is especially the young members of our profession against whom our correspondent directs his remarks, for he says, "There are rumours and statements going abroad, which deserves attention, that young unmarried girls, not of doubtful character, but strictly virtuous, are often tampered with, so as to allow the introduction of the vaginal speculum. . . . I am told that visitors in the families of these victims of quackery (?) are often invited and urged to see the evidences of disease, real or imaginary. I do not know how a remedy for these evils can best be applied, but there should be no delay in doing anything possible for this object; and for those guilty of such degradation, language is hardly capable of too severe denunciation."

In these days of poly-speculation, when we seem jumping out of the swaddling clothes which our forefathers left about us, are disposed to submit each organ of the body to every species of investigation which the fertile brain of man can devise, it would be strange indeed if we did not assume too frequently to throw light on regions where light need not go. Grant that we need more knowledge of the diseases of women, as we do of every other branch of disease, and that so many of her ailings are due to pathological conditions of the organs of generation; grant the assertions of those who have come from the schools of Europe in reference to the facilities for observation enjoyed there, and their complaints that the hospitals and dispensaries here do not offer them similar advantages; grant this, and, notwithstanding, we do not hesitate freely to say that vaginal examinations *are* too frequently and unnecessarily made. The glory of a true woman is that shrinking delicacy which dreads exposure, in whatever way it may come; her only shame, its loss. She comes to her physician as a confidant to a friend, and every needless exposure serves only to blunt the sensitive nature which is her sex's heritage, an exposure we have no *right* to ask her to submit to.

Of those who would compare Europe with America in its clinical advantages in this respect, the question might well be asked if, on comparing the mental, moral, and social condition of the peasant class, of Austria, for instance, with that of even the lowest class among our own native population, any friend of humanity would, for the sake of instruction, place our own women on the plane of the European.

This is no new subject; it has been thoroughly discussed at various times; but we cannot refrain from expressing the views which we entertain, and which are suggested by our correspondent. So far as may be *necessary* to ascertain the cause of disease in our patient, so far as may be advisable for the absolute *needs* of clinical instruction, is it our privilege to use the speculum, and even then only in such a manner as may preserve those feelings which are the *right* of woman.

"True clinical teaching like this would meet with full approval from all who wish well to medical education; but to uncover an unfortunate woman in a college amphitheatre in presence of a hundred or more students, is a proceeding the agony of which is not compensated by any adequate advantage to the class."

We find this ulceration on our professional os so well touched up by our contemporary, the senior editor of the *Pacific Medical and Surgical Journal*, that we cannot help giving a quotation from his remarks to close the subject.

"Now let us come home and bring to judgment a sin in the family. Within the profession there is a species of quackery which is advertised, not by the printing press, but by the uterine speculum. There prevails very extensively among our women a singular disorder, of which the most prominent symptom is a passion for uterine explorations. To some extent medical practitioners are responsible for the general prevalence of this malady. It is easy for sensitive females to persuade themselves that their afflictions, from the toothache downwards, are due to falling of the womb, or ulcerations or tumours; and he is the sharpest doctor who first detects the difficulty. Here comes in the charlatan, to exaggerate the disease, if there be any, and to beguile the patient with promises of cure. Henceforth the speculum becomes to the poor woman an essential part of the daily routine of life. Caustic, the knife, and various manipulations, look like work; and she is charmed with the industrious and energetic attentions of the professional mechanic. By and by the bubble bursts; and for all the good that has been done by subjecting the uterus to a course of torture, its proprietor might as well have adopted the treatment accredited to that miracle of scientific skill, Li-potai, namely, the application of a blister to the crown of the head to raise the fallen womb to its place.

"It is to be hoped that the fashion of women to mistrust and slander their wombs and rejoice in having them explored and tinkered, has passed its culmination; and with it the professional mania for persecuting that organ. The highest authorities have taken the back course and condemned their own uterine surgery in some respects. We may, therefore indulge reasonable expectation that the uterus will shortly withdraw from public exposure, and regard the decencies of private life."

Influence of Mercury in Preventing the Death of the Fœtus in Constitutional Syphilis.

In the *Weiner Med. Wochenschrift*, Dr. Julius Löwy reports the results of his observations. Of 99 pregnant females, who were syphilitic, 37 were subjected to inunction with mercurial ointment, and in 33 the child lived. Löwy tabulates his results thus:—"Abortion: In those subjected to treatment, 13·5 per cent.; in those not treated, 29·5 per cent. Living children in those treated, 75·6 per cent.; fœtus macerated in those not treated, 76·4 per cent." He infers that mercury has no injurious influence on mother or child, and that it does not tend to induce premature labour.

Experiments on the Effects of Alcohol (Ethyl Alcohol) on the Human Body. By E. A. Parkes, M.D., F.R.S., Professor of Hygiene in the Army Medical School, and Count Cyprian Wollowicz, M.D., Assistant Surgeon, Army Medical Staff.

(From the *Proceedings of the Royal Society*.)

As a knowledge of the physiological effects of alcohol on the human body is a matter of great importance, and as previous observations leave some points in doubt, we took the opportunity which the willingness and zeal of a very intelligent healthy soldier afforded us of investigating this subject. In order not to lengthen the paper, we have given only our own observations, without referring to those of others.

The plan of observation was as follows:—For twenty-six days the man remained on a diet precisely similar as to food and times of meals in every respect, except that for the first eight days he took only (in the shape of coffee, tea, and simple water); for the next six days he added to this diet rectified spirit, in such proportion that he took, in divided quantities, on the first day one fluid ounce (= 28·4 cub. centims.) of absolute alcohol; on the second day two fluid ounces; on the third day four ounces, and on the fifth and sixth days eight ounces on each day. He then returned to water for six days, and then for three days took on each day half a bottle (= 12 ounces, or 341 c. c.) of fine brandy, containing 48 per cent. of alcohol. Then for three days more he returned to water.

There were thus five periods, viz., of water-drinking, alcohol, water, brandy, water.

Before commencing the experiments, the man, who had been accustomed to take one or two pints of beer daily, abstained altogether from any alcoholic liquid for ten days.

This man, F. B., is twenty-eight years of age, 5 feet 6 inches in height, and his usual weight is 134 or 136 lbs. He is finely formed, with little fat, and with largely developed powerful muscles; he has a clean smooth skin, a clear bright eye, good teeth, and is in all respects in perfect health. He is very intelligent, and assisted us so much that we are quite certain that there has not been a mistake even for a minute in the time of taking the temperatures and passing the urine. As he had always been accustomed to smoke, we thought it proper to allow him half an ounce of tobacco daily, for fear the deprivation of it might disturb his health.

In addition to the experiments recorded in this paper, we tested the accuracy of his vision, and the muscular power before and during the use of alcohol; but as we could not detect any difference, we do not give the experiments.

Our object being to test the dietetic effects of alcohol, we gave it in small and large quantities, but avoided producing any extreme symptoms of narcotism.

General Conclusions.—1. One and two fluid ounces (28·4 c. c. and 56·8 c. c.) of absolute alcohol given in divided quantities in 24 hours to a perfectly healthy man seemed to increase the appetite. Four fluid ounces lessened it considerably, and larger quantities almost entirely destroyed it. On the last day of alcohol the man was three-quarters of an hour eating 8 ounces of bread, and could hardly do so. Had he been left to his own wishes, the amount of food taken would have been much diminished.

It appears, therefore, that in this individual some point near 2 fluid ounces of absolute alcohol is the limit of the useful action on appetite; but it is possible that if the alcohol had been continued, a smaller quantity would have lessened appetite.

In other healthy persons it may be different from the above; in most cases of disease, when digestion is weakened, it seems probable that a much smaller amount of alcohol would destroy appetite.

2. The average number of beats of the heart in 24 hours (as calculated from 8 observations made in 14 hours), during the first or water period, was 106,000; in the alcoholic period it was 127,000, or about 21,000 more; and in the brandy period it was 131,000, or 25 000 more.

The highest of the daily means of the pulse observed during the first or water period was 77·5; but on this day two observations are deficient. The next highest daily mean was 77 beats.

If, instead of the mean of the 8 days or 73·57, we compare the mean of this one day, viz., 77 beats per minute, with the alcoholic days, so as to be sure not to over-estimate the action of the alcohol, we find:—

On the 9th day, with one fluid ounce of alcohol, the heart beat 4,300 times more.
On the 10th day, with 2 fluid ounces, 1,872 times more.
On the 11th day, with 4 fluid ounces, 12,960 times more.
On the 12th day, with 6 fluid ounces, 30,672 times more.
On the 13th day, with 8 fluid ounces, 23,904 times more.
On the 14th day, with 8 fluid ounces, 25,488 times more.

But as there was ephemeral fever on the 12th day, it is right to make a deduction, and to estimate the number of beats in that day as midway between the 11th and 13th days, or 18,432. Adopting this, the mean daily excess of beats during the alcoholic days was 14,492, or an increase of rather more than 13 per cent.

The first day of alcohol gave an excess of 4 per cent., and the last of 23 per cent.; and the mean of these two gives almost the same percentage of excess as the mean of the 6 days.

Admitting that each beat of the heart was as strong during the alcoholic period as in the water period (and it was really more powerful), the heart on the last two days of alcohol was doing one-fifth more work.

Adopting the lowest estimate which has been given of the daily work done by the heart, viz., as equal to 122 tons lifted one foot, the heart during the alcoholic period did daily work in excess equal to lifting 15·8 tons one foot, and in the last two days did extra work to the amount of 24 tons lifted as far.

The period of rest for the heart was shortened, though perhaps not to such an extent as would be inferred from the number of beats, for each contraction was sooner over.

The heart on the fifth and sixth days after alcohol was left off, and apparently at the time when the last traces of alcohol were eliminated, showed in the sphygmographic tracings signs of unusual feebleness; and perhaps in consequence of this, when the brandy quickened the heart again, the tracings show a more rapid contraction of the ventricles, but less power than in the alcoholic period. The brandy acted, in fact, on a heart whose nutrition had not been perfectly restored.

The peripheral circulation was accelerated and the vessels were enlarged; and the effect was so marked as to show that this is an important influence for good or for evil when alcohol is used.

Referring only to this healthy man, it is clear that the amount of alcohol the heart will bear without losing its healthy sphygmographic tracing is small, and it must be supposed that some disease of heart or vessels would eventually follow the overaction produced by large doses of alcohol.

3. Although large doses of alcohol lessened appetite, they did not appear to impede primary digestion, as far as this could be judged of by the sensations of the man; nor did they seem to check the normal chemical changes in the body which end in the elimination of nitrogenous excreta, of phosphoric acid, and of free acidity. In other words, we were unable to trace either the good or the evil ascribed to alcohol in this direction: it neither depressed these chemical changes nor obviously increased them; it neither saved the tissues nor exhausted them; and even in the period of ephemeral fever its effects were negative.

But, of course, in these experiments we were not dealing with diseased tissues, nor with structures altered in composition by long-continued excess of alcohol. The results in such cases might be different; and it may be desirable to repeat that though appetite was lessened, the amount of food taken was the same each day.

4. Neither pure alcohol nor brandy, in the quantities given, lessened the temperature; in other words, they did not arrest the chemical changes which produce animal heat, or lessen the processes which regulate its amount, any more than they influenced nitrogenous tissue-change. Alcohol in no way influenced the rise of temperature during the attack of ephemeral fever; it neither lowered nor increased it. This appears to us conclusive against the proposal to use alcohol as a reducer of febrile heat.

On the other hand, it is not clear that alcohol increased the temperature: it produced subjective feelings of warmth in the stomach, in the face, round the loins, and over the shoulders; but at the same time when these were felt (for about one hour after tolerably large doses) the thermometer in the axilla and rectum showed no rise. This is best seen by comparing the two o'clock observations, which were taken about half an hour after dinner. The feelings result from the enlargement of the vessels and the greater flow of blood through them; so also, the ephemeral fever was decidedly not made worse by it.

5. An effect on the nervous system was not proved by any evidence of increase or decline in the amount of phosphoric acid; but there were marked subjective feelings; and possibly, also, the increased action of the heart was a nervous condition, as the short contractions of the ventricle were like those ascribed to alterations in the nervous currents. The feelings which were produced by four fluid ounces daily, and in a still higher degree by the larger quantities of alcohol, proved that narcotism was produced. There was no exhilaration, but a degree of heaviness, indisposition to exertion, and loss of cheerfulness and alacrity; there was slight headache, and even some torpor and sleepiness. All these effects were more marked with brandy. The commencement of narcotism was therefore produced in this man by some quantity much less than 4 fluid ounces, and probably nearer 2. It was nearly this amount which also commenced to destroy the appetite; and it may also be observed that a considerable rise in the frequency of the pulse occurred on the third day of alcohol, when 4 ounces were taken, whereas on the days with one or two ounces the pulse, though quickened, was so in a much less degree.

Putting, therefore, these points together, viz., that the obvious effect on the nervous system (*i. e.*, narcotism), the loss of appetite and a great rise in the quickness and frequency of the heart's beats occurred at the same time, it seems fair to conclude that there must be a relation between the phenomena, or, in other words, that all were owing to nervous implication.

It appears, then, clear, that any quantity over two ounces of absolute alcohol daily would certainly do harm to this man; but whether this, or even a smaller quantity, might not be hurtful if it were continued day after day, the experiments do not show. It is quite obvious that alcohol is not necessary for him; that is, that every function was perfectly performed without alcohol, and that even one ounce in twenty-four hours produced a decided effect on his heart, which was not necessary for his health, and perhaps, if the effect continued, would eventually lead to alterations in circulation, and to degeneration of tissues. It is not difficult to say what would be excess for him; but it is not easy to decide what would be moderation; it is only certain that it would be something under two fluid ounces of absolute alcohol in twenty-four hours.

It will be seen that the general result of our experiments is to confirm the opinions held by physicians as to what must be the indications of alcohol both in health and disease. The effects on appetite and on circulation are the practical points to seize; and if we are correct in our inferences, the commencement of narcotism marks the point when both appetite and circulation will begin to be damaged. As to the metamorphosis of nitrogenous tissues or to animal heat, it seems improbable that alcohol in quantities that can be properly used in diet has any effect; it appears to us unlikely (in the face of the chemical results) that it can enable the body to perform more work on less food, though by quickening a failing heart it may enable work to be done which otherwise could not be so. It may then act like the spur in the side of a horse, eliciting force, though not supplying it.

The employment of alcohol in health and disease is so great a subject that we should have felt tempted to extend these remarks to some points of medical practice, had it been desirable to do so in this place. We will only say that while we recognise in these experiments the great practical use of alcohol in rousing a failing appetite, exciting a feeble heart, and accelerating a languid capillary circulation, we have been strongly impressed with the necessity for great moderation and caution. In spite of our previous experience in the use of alcohol and brandy, we were hardly prepared for the ease with which appetite may be destroyed, the heart unduly excited, and the capillary circulation improperly increased. Considering its daily and almost universal use, there is no agent which seems to us to require more caution and more skill to obtain the good and to avoid the evil which its use entails.

We wish to guard ourselves against the supposition that in speaking of alcohol and brandy we refer at all to wine and beer, which contain substances, in addition to alcohol, which may make their action in nutrition somewhat different.

Mortality of Lying-in Women in Norway.

According to the *Gazette Hebdomadaire*, the deaths in Norway in 270,000 accouchements were as one to 138. The proportion of twins was not less than one in 83.

Citric Acid in After-Pains.

Dr. J. B. Chagnon, in the *Canada Medical Journal* for May, recommends citric acid for the pains following labour, and declares that it has never failed in his hands. He gives five grains in two or three ounces of water every five hours. It acts as a nervine, and as a preventive of inflammation.

Moulds for Suppositories.

A writer in the *Amer. Jour. of Pharmacy* proposes an extemporized mould for suppositories, made by folding white paper in the form of a cone. He supports the moulds in holes made in the lid of a cigar-box. Such moulds can be used only once.

Chloroform Prepared from Chloral.

A German chemist (*Amer. Jour. of Pharmacy*) says that the best and only rational mode of preparing chloroform for internal use is from chloral hydrate. Thus prepared it has a specific gravity of 1·5, and is not altered by sunlight.

Chloride of Zinc Paste.

Dr. Mayet (*Bull. de Therap.*), states that, he has found a great advantage from adding oxide of zinc to the ordinary mixture of chloride and flour. By using eight parts of chloride, two of oxide, and six of flour, a paste is got which does not deliquesce after it is dried, and yet acts as a caustic with undiminished efficacy.

Action of Roasted Opium.

Dr. Fronmuller (*Deutsche Klinik*), has tried this substance (known under the name of Chandu) in fifty cases. He found that as a hypnotic it is very much the same as ordinary opium; but that it causes less stupor, and less frequently produces giddiness, itching, and other disagreeable sequelæ.

Medical News.

St. Thomas's Hospital.—The following distribution of prizes took place on Saturday last:—*Third Year's Students.*—A. J. Drake, Kingsclere, college prize, 30*l.* and hon certificate; J. S. Slater, Bath, college prize, 20*l.* and hon. certificate; E. Sergeant, Preston, college prize, 10*l.* and hon. certificate; *Second Year's Students.*—B. Addy, West Deeping, college prize, 30*l.* and hon. certificate; W. Garton. St. Helier's, college prize, 20*l.* and hon. certificate; *First Year's Students.*—J. Boulger, Gravesend, Sir Wm. Tite's Scholarship and hon. certificate; A. V. Maybury, Frimley, college prize, 20*l.* and hon. certificate; A. H. Lavers Rayleigh, college prize, 10*l.* and hon. certificate; "*Physical Society's*" *Prizes.*—R. Cory, Carlisle, society's third year's prize, and hon. certificate; S. Osborn, Brixton, society's third year's prize; B. Addy, West Deeping, society's second year's prize, and hon. certificate; W. Garton, St. Helier's, society's second year's prize, and hon. certificate; *Surgery and Surgical Anatomy.*—E. Sergeant, Preston, Cheselden Medal, founded by George Vaughan, Esq.; *For General Proficiency and Good Conduct.*—J. S. Slater, Bath, Treasurer's gold medal.

Death while under the Influence of Chloroform.—On Wednesday evening Dr. Lankester investigated a case at the Royal Free Hospital in which a patient there died whilst under the influence of chloroform. The deceased, who was a stableman, aged thirty-four years, a short time since met with an injury to one of his fingers. He went to University College Hospital, where the limb was dressed, but on Wednesday last complained of his jaw, and went to the Royal Free Hospital in consequence. The surgeons there, perceiving that the man was suffering from tetanus, deemed it advisable to amputate the finger, and upon being taken to the operating theatre he was placed under the influence of chloroform by Mr. Thomas, one of the House-surgeons. After inhaling the drug for three or four minutes he expired. Mr. Thomas stated the duty of chloroformist was undertaken in turns, and that on previous occasions he had administered chloroform to patients. Dr. Lankester observed that a young medical man must have a beginning, and that in the present case everything had been done that was consistent in medical practice. Mr. Dickson, one of the house-surgeons said, that every precaution was taken, and the coroner having re-stated the case to the jury, a verdict of "Death from tetanus, accelerated by chloroform," was recorded.

A Scheme for Purifying a River.—The question of preventing the pollution of rivers by sewage acquires constantly increased importance. We some time ago alluded to the state of the Trent as it flows through the grounds and past the beautiful mansion of the Duke of Sutherland at Trentham, in Staffordshire. It has been changed, within a few years, from a clear to a filthy and offensive stream, by the influx of the sewage of the Pottery towns. Mr. Loch, Q.C., agent of the Duke of Sutherland, has drawn up a bill for the abatement of the nuisance. It proposes to create two distinct bodies, the one active and the other preventive. First a Joint Committee of the several Local Boards in the valleys of the streams forming or flowing into the Upper Trent is to be formed, with power to provide the necessary means of so dealing with the sewage of the towns as that it shall no longer flow into the Trent, or its tributaries, until the water shall have been rendered pure. The cost is to be met by the various Local Boards in proportions to be fixed by the Joint Committee, or failing their agreement, by a paid standing Arbitrator, to be appointed by them. The other body to be appointed is an Upper Trent Conservancy Board, to consist of persons chosen by the landowners in the valley, and their duties will be of a repressive character. First, they are to be empowered, after the 1st of March, 1872, to prevent, by serious penalties, any person making any new drain, or other outlet, to discharge sewage into any sewer, ditch, or stream, &c., which flows into the river. After that date they may give notice for the discontinuance of the flow of sewage by any previously existing channel, and not less than a year, or more than three years, are to elapse before such notice shall expire, and such previously existing sewer be absolutely prevented from being discharged into the river. The result would be that by the date named the flow of any additional sewage into the Trent would not be allowed, and at the most, within three years afterwards, all existing drainage must be dealt with so as to be divested of its noxious matter before reaching the river. The local authorities of the district have not yet considered this bold proposal. Should it be carried out it may become a model for general legislation with a like object. We observe that a meeting of the representatives of the principal Corporations and Local Boards in the valleys of the Aire and Calder was held at Leeds on Monday, to consider this important question, and it was determined that it is desirable to introduce a bill into Parliament next Session, dealing with the whole question of the purification of streams.—*Derby and Chesterfield Reporter.*

NOTICES TO CORRESPONDENTS.

An Ancient Physician's Prophecies realised in the present War.—The author of "The Rosicrucians," in a letter to the editor of the *Standard*, gives, amongst other remarkable predictions said to have been realised in past times, the following, which is a translation from the ancient French:—

"Peace comes on one side—war on the other,
There never was revenge so overwhelming!
But men and women shall bemoan, and innocent blood shall be shed,
And these things shall be in France all round.

"Too great reliance shall betray the monarch.
The end shall begin in France,
With secret omen fatal to One."

The author was Michael Nostradamus, a celebrated physician of Florence, attached to the person of Henry the Second of France. The *Seven centuries* from which the above is a quotation, was published in 1555, eleven years before the writer's death.

A Sufferer.—Don't go near the advertising fellow. Consult the usual attendant in your father's family, and if further advice be needed he will tell you to whom to go.

J. B.—The article is not adapted for a medical paper.

Students.—Messrs. Churchill's are the publishers of the manual. The French work could probably be procured through Baillière and Co.

A. Hind.—The work was forwarded to the address indicated.

J. Paul.—The names of the reporters have not been published. The work done speaks for itself.

T. C. D. asks for a condensed statement of the regulations for the new diploma in State medicine.

Macabio.—Be so kind as to write another letter.

T. B.—The college is one of the most respectable in the kingdom.

L.S.A.—You had better at once register and then take a surgical diploma.

Dr. Macby.—The statement as we said a fortnight ago was too good to be true. We fear it is not at all likely that Government will take any such step. Most people entertain the idea that there is no probability at all of such a loan as was spoken of at the Association being considered.

L. P.—The publication named is utterly worthless.

THE ENGLISH POOR-LAW MEDICAL OFFICERS' SUPERANNUATION ACT.

To the Editor of "The Medical Press and Circular."

Dear Sir,—We thank you for the Abstract and Clauses of this Act; has it been carried out in Ireland as yet!! and with what effect!

Will you in your next publication explain, or as early as you can, agreeable to the point at issue. In Article III., it is expressed that a person must be over sixty years of age: and further, that he must have served as an officer of some union or parish for twenty years at least; rather sharp, should think that there are very few who would reach the mark, but still, will a person who has served eight years in a union within England and Wales, and another term of twelve years and upwards in two different counties, come within the meaning of the Act? or say eight in Somerset and twelve in Devon claim superannuation?

Your obedient servant,
A Constant Reader.

[The Act requires that the recipient of superannuation shall be over sixty years of age, or shall have become disabled by infirmity or ill-health, but it is not necessary that he shall have served for twenty years in the same district.—Ed. Med Press and Cir.]

Accepted Papers acknowledged from Dr. Francis Luther, "On Scarlatina;" Dr. Martin, "On Subcutaneous Injection of Morphia;" Dr. Thos. Hayes, "Removal of a large Naso-pharyngeal Polypus with Wire Ecraseur;" Dr. Kinkead, "On a New Digestive, being a combined solution of Pepsine and Pancreatine."

Literary Criticism in America.—The *San Francisco News-Letter* says, "We have received for review a pamphlet entitled, 'The Discoveries of Prof. R. Leonidas Hamilton, M.D.' We have ourselves made a discovery, and it seems to be this:—Professor R. Leonidas Hamilton is a blockhead, compared with whose intelligence that of a born idiot is transcendent omniscience, and a knave in whose presence a professional thief would blush to the eyes with conscious rectitude."

APPOINTMENTS.

Anderson, J. F., M.D., Medical Officer for the Hampstead South District of the Metropolitan Mutual Medical Aid Society.

Badcock, Dr. L. C., Out-door Medical Officer for the Western District of the Brighton Union.

Barrett, J. J., M.D., Medical Officer for the Lambeth District of the Metropolitan Mutual Medical Aid Society.

Buck, A. H., L.R.C.P.Ed., Medical Officer for the Kentish-town District of the Metropolitan Mutual Medical Aid Society.

Clark, Mr. A., Senior House-Surgeon to the Middlesex Hospital.

Crosse, T. H. B., M.R.C.S., Medical Officer for the Kensington District of the Metropolitan Mutual Medical Aid Society.

Davidson, Dr. A. D., Ophthalmic Surgeon to the Royal Infirmary, Aberdeen.

Gowland, J. E., M.D., Medical Officer for the Holborn District of the Metropolitan Mutual Medical Aid Society.

Lathay, W. H., M.R.C.S., District Surgeon to the Salford and Pendleton Royal Hospital and Dispensary.

Magor, T., L.R.C.P.L., Medical Officer for the Hornsey District of the Metropolitan Mutual Medical Aid Society.

Nicholls, H. H. J., M.R.C.S., Resident House-Surgeon at the Brighton and Hove Lying-in Institution.

Norris, P. J., M.D., Medical Officer for the Southern District of the Lancaster Union.

Pope, Dr. Medical Officer for the Tramore Dispensary District of the Waterford Union.

Robinson, R. B., L.R.C.P.Ed., Medical Officer for District No. 3 of the Southmolton Union, Devon.

Sandford, H. V., M.D., Medical Officer for District No. 2 of the Bodmin Union, Cornwall.

Wallace, F. W., L.R.C.P.L., Medical Officer for the Hoxton District of the Metropolitan Mutual Medical Aid Society.

Wallace, R. U., M.B., Medical Officer for the Dalston District of the Metropolitan Mutual Medical Aid Society.

Waters, J. H., M.B, Medical Officer for the Kingsland District of the Metropolitan Mutual Aid Society.

Watkins, E. T., M.D., Medical Officer for the Bloomsbury District of the Metropolitan Mutual Medical Aid Society.

Welch, R. R., M.R.C.S., Medical Officer for the Clapton District of the Metropolitan Mutual Medical Aid Society.

Young, E. P., M.R.C.S., Medical Officer for the Edgware-road District of the Metropolitan Mutual Medical Aid Society.

VACANCIES.

Queen's Hospital, Birmingham.—Resident House-Surg. Salary £100.

Bodmin Union.—Medical Officer. Salary, inclusive of fees, £30 15s.

Dorset County Hospital.—House-Surgeon. Salary, £80 with board.

Tower Hamlets' Dispensary.—Medical Officer, Salary £100 with residence.

Kells Union.—Medical Officer. Salary £100, exclusive of fees (see advertisement.)

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Advanced Text Book of Zoology. By Alleyne Nicholson, M.D. Edinburgh: Blackwood and Sons.

The Treatment and Utilization of Sewage. By W. H. Corfield, M.A., M.B. London: Macmillan and Co.

University College, London. Calendar for 1870-71. London: Jas. Walton.

Transactions of the St. Andrew's Medical Graduates' Association.

Diseases of the Heart among Soldiers. By Arthur B. R. Myers, M.R.C.S. London: John Churchill and Sons.

Marriage.

Long—Cooper.—On the 12th ult., at the Parish Church, Cromer, Norfolk, Mark Long, M.D., of Barking road, Canning town, Essex, to Sophia Amelia, eldest daughter of James Cooper, F.R.C.S., of Colne Lodge, Cromer.

Deaths.

Berncastle.—On the 30th of June, at Melbourne, Julius Berncastle, M.D.

Chawner.—On the 13th ult., at Lichfield, Richard Croft Chawner, only surviving son of the late Dr. Rupert Chawner, aged 65.

Gill.—On the 17th ult., at Dover, Nathaniel B. Gill, M.R.C.S., aged 49.

Waters.—On the 14th ult., E. W. Waters, L.K.Q.C.P.I., of Tramore, Co. Waterford.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

Introductory Lecture

DELIVERED AT

THE LONDON HOSPITAL.

BY

H. G. SUTTON, M.D., F.R.C.P.,

Assistant Physician and Lecturer on Physiology.

WHATEVER may be said as to the advisability of doing away with Introductory Lectures, it is, in the opinion of many, a beneficial thing for us to assemble at the opening of the Medical Educational year.

Permit me now to speak not only to the medical student but to the student of medicine; not to those only who are working for a diploma, but to those who never cease working, that every year may make them better fitted for the prevention and cure of disease. The medical student is doing little more than learning how to learn; whilst he is gathering facts he is, or ought to be obtaining a method of study. And what I have most at heart is to point out, imperfectly and obscurely it must be, certain general principles which will I hope show how our several departments of study bear on the one great task of our lives, the cure of the sick. In this Introductory Lecture it is my duty to remember that some of you gentlemen who have honoured the London Hospital Medical School with your presence this day are engaged in the practice of medicine. Some of you gentlemen have almost completed and some are about to commence their medical education.

All who have studied medicine are, I believe, prepared to admit that the education of a medical man is never completed. None of us have completed our education; I therefore venture to think that the subject of medical education concerns all of us.

Some students appear to conclude that they are sufficiently educated when they have attended some lectures and demonstrations; when they have been a few times in the wards and obtained the necessary signatures to their schedules. It should be the ambition, and it certainly is the duty of every student to obtain all the knowledge and skill that lies open to him, in order that he may relieve the sufferings of his fellow creatures. He should also do this for his own happiness, for he will find that comparatively few persons in the medical profession gain large incomes. The student should, therefore, strive to gain the commanding position awarded to knowledge. Medicine is defined to be the science and art of preventing, curing and alleviating the diseases of the human body.

By art is understood the power or skill in the use of knowledge; in our profession it means the practice of medicine. By science, is understood knowledge, or a collection of general principles which are useful as guides to sound medical practice.

It is an accepted opinion, that no person can understand man in disease, who does not study man in health. Therefore, the conditions of the body and mind in health are first studied in the sections—anatomy, physiology, and animal chemistry, and in order that the student may rightly understand the physiology of man himself, he is required to study also the physiology of other members of the animal kingdom under the head of comparative anatomy and physiology, and to study the physiology of the vegetable kingdom in the section on botany. The knowledge included in all these subjects is called the science of physiology.

Afterwards, the condition of the body in disease, are studied in the divisions, morbid anatomy, pathology, and pathological chemistry; and the knowledge included in these divisions form the science of pathology. The art of medicine is taught in the lectures on medicine, surgery, midwifery, therapeutics, and forensic medicine. The art of preserving health, is described in the lectures on hygiene. Each of us, therefore, aims to be a physiologist, a pathologist, and a practitioner.

The student of medicine, in learning physiology begins with the tissues of the body. He studies their structural condition. Having done this, he ascertains in what manner the different tissues are connected with each other and, finally, he observes how they collectively work. After the tissues, he examines the viscera of the body, and by a similar process, endeavours to find out how the several organs of the body act together, to form the one organization, man. In this way, he synthetically, in his own mind, forms man. The physiologist investigates man in still another way. He studies him in his individual condition. He examines his ideas, his sensations, his movements and secretions. He studies the organization in action, and in this manner he endeavours to find out how the vital dynamics of man's system results from the elaborate arrangement of tissues and organs. This analytical examination reveals that the tissues and organs have dynami-

cal properties which could not have been inferred from the minutest investigation of their component cells and fibres.

All the parts of the body are noticed to work independently, but all uniformly and correlatively. Every viscus and every tissue, has its own specific actions, each cell, its own life, and the sum of these make up the life of man.

It is further observed that each man has his own distinguishing peculiarities, dynamically and structurally, and these peculiarities apparently pervade his entire body.

Let us illustrate this:—A man is short, he has small hands and feet, slender bones, his heart's action is irritable, easily disturbed, his muscular system is fairly developed and his movements are somewhat quick and excitable; and we must not neglect to add that his appetite is good, and he enjoys good eating and drinking.

So much for the physical man, and now for the mental peculiarities which go with such a build and temperament. His manner of speaking is decided and abrupt. He is sensitive. His ideas flow quickly, but they are not so well co-ordinated. He has decided views, but not large views of things. He is impulsive in his conduct. He is more dogmatic than logical, and apt to be both obstinate and passionate. When we take into consideration the whole of his peculiarities, mental and bodily, we find that there is one type of action pervading his whole organization.

When man's features are well defined, the novelist delights to portray him, and often does so accurately, but perhaps in an exaggerated form. When I think of a man, such as I have described, the popular hero Mr. Pickwick, appears before my mental view.

The physiologist has to determine how it comes about that one type of action exists throughout the man's body; and what are the conditions which have developed these peculiar actions.

It is observable, as we have just remarked, that a particular conformation of body is associated with certain mental characters. We may conclude therefore, that the very same conditions which created his limbs and viscera, also developed his mental and emotional characters. He has derived his body, and in consequence, his mind from his parents. But as he grows up *external conditions* have a large share in modifying his inherited structures and functions. Internal influences and external conditions have developed this man with his precise build and actions, and, as the whole of his body was exposed to the same general conditions, it follows, that the one type of action is found in every part of the man's system. The physiologist, therefore, endeavours to find out what are the particular agencies which, continually produce the peculiarities in build and temperament of the body. He, like other scientific observers, discovers that a series of events are uniformly followed by a series of other events, and this knowledge is the science of physiology.

Inherited structures and external conditions are the two factors concerned in the growth and development of every living thing. The external conditions which act on man's vegetative life are, to a large extent, the same as those which act on every animal and plant. But many external conditions, and many at one time, are operating on man; but on plants and animals, comparatively few. Therefore, the physiologist, who has to define the influence of *each condition*, may for some things gain *even more information* in his researches from a wise study of animals and plants than from the study of man. I therefore, strongly recommend you to work at comparative anatomy and physiological botany.

Before leaving this part of the subject, I would urge you to pay attention, not only to what we may suppose to be the direct causes of particular diseases, but also to those large general influences which affect for good or evil the whole organization of man. Such influences as those of light, changes in temperature, of varieties in climate—of elevated, dry or low moist localities, and we must not neglect those influences which act still more indirectly, such as religion and politics.

In their anatomical form and as a consequence their physiological state, men obviously differ one from another very much. If we select three men, each of whom is considered to be healthy, we observe that they are unlike each other in their power of hearing, seeing, smelling; in their sensibility to pain, to heat, and cold; their modes of muscular action are very different, the power of their circulation, respiration and digestion vary, and their mental or as we may say their brain states are also very dissimilar. Yet each of these three persons is properly considered to be in good health, because they have not experienced any particular suffering and they have had their individual peculiarities of structure and function from childhood. Physiology for the sake of convenience describes a *typical or ideal man*, but it is only a standard assumed to facilitate teaching. It is most important that every practitioner should appreciate the physiological deviations from this ideal standard. It is necessary to know their deviations to understand pathological varieties. These three men differ from each other in their physiological state, and, they will differ while suffering from what we must call the same disease, notably in rheumatic fever. Their modes of action, sensibilities, and ideas, are different whilst they are in health; and their pains, symptoms, complaints are very different, while each labours under the same disease. In order to know what value is to be attached to their differences in disease, it is necessary that medical men should know the peculiarities of each individual while in health, and to accomplish this, he should study the physiological characters, not of *an ideal standard man*, but *of many varieties of men.*

At first sight it would appear that men are at once so like and so unlike, in so many ways, in so many degrees, that it is extremely difficult for the mind to appreciate individual varieties and next to impossible to systematize them in a manner to be useful in every day practice. But further consideration tends to show that it is to be done by careful study.

We observe that persons differ from the ideal standard of physiologists, yet particular differences are so present in some that a useful classification can be made.

If many men were mixed promiscuously, and if afterwards each man were examined, and his build and physiological characters were well described in writing, they would appear to vary in every degree. Yet a careful analysis would show that there are broad principles of arrangement. They can be classified according to the build of their skeletons; according to the condition of their muscular system; according to the degree of development of their circulatory, respiratory digestive and nervous systems. We should find that, amidst all the seeming confusion there is *order*. An arrangement is possible; men are, I believe, to be naturally classified by their resemblance in structure and vital dynamics, and each class has its own standard of health. The old physicians recognised the importance of classifying man on some such method, and they did so under the names temperaments or constitution. By temperament, is still understood a peculiar organization of the body common to many individuals, which influences their mental operations, bodily processes, and their particular diseases.

Every person who practises medicine must have observed how difficult it is to understand many symptoms which a patient complains of, and the puzzling matter is that, in almost every person, the symptoms differ in intensity and often in kind. These symptoms in no way belong to the disease; but is it not at least as correct to say they belong to the temperament. May not the physician conclude that they are expressive rather of the state of the individual, than of the disease itself. At all events, I am satisfied myself that we shall not be able to give *such symptoms* their *true value*, until we obtain clear ideas of the kind of man who is suffering, as well as of the disease. This kind of knowledge the student of medicine cannot obtain by examining the cells and fibres of the body microscopically and chemically and the organs anatomically. He can only gain it by studying varieties of constitutions in health or in other words differences in temperament.

Besides noting the original temperament which the man inherits, we must for medical purposes, consider not only his histological and physiological development, but *his personal habits*, and the general circumstance of his condition of life. We must ascertain how foul air, improper food, ill controlled passions have affected his organization, even we may say, educated his viscera in order that we may know how his system will act when again submitted to the same conditions.

In investigating temperaments the student should follow the course adopted in all physical investigations; commence with well marked instances of each class. He will soon discover that with temperaments, as with all orders of living things, there are no abrupt boundaries separating one from another. The characters distinguishing one class, merge in particular individuals insensibly, into or are mixed with characters indicating another class. He will in other words, observe that a certain number of persons have mixed constitutions or temperaments.

Having gained an insight into physiology the "science of the normal," the student proceeds to make himself acquainted with pathology, the "science of the abnormal." Pathology

teaches the causes, nature and, as I think it should, the course of diseases also. The pathologist studies his subject in a parallel manner to that of the physiologist. He examines the tissues and organs of the body after death, and observes the altered dynamics during life. As is often said, all pathological changes must be viewed by the light of clinical experience. We, as pathologists, could never understand pneumonia by simply examining the lungs after death, no more than a man could understand a thunder storm by simply examining a tree which had been struck by the lightning.

Observation shows that men with very slender bones, long flat chests, irritable feeble hearts, feeble digestion, ill developed muscular systems—whose brain and nerve actions are incapable of prolonged activity, are very liable to die of consumption. They have the nervous temperament and further they are liable to disease of the mucous tissues, or in other words, they have the mucous diathesis. We therefore observe that, with a peculiar build of body, there is a particular standard of health and a liability to particular pathological changes. The build or formation of body is, as we have already remarked, *dependant partly on inheritance*, and *is largely affected by external conditions*. Therefore the liability to disease or the diathesis, depends also on hereditary and external conditions. The pathologist endeavours to find out, not only what abnormal changes these conditions excite in the body of this build, but also to define what specific conditions are uniformly followed by specific pathological changes. He seeks to discover the relations of facts. The tendency of certain events to be uniformly followed by other events, This knowledge constitutes "science" and on this basis we may have a science of pathology.

Daily experience shows that some persons are constructed in a manner so as to withstand strongly, some so as to withstand feebly, the influence of external conditions. Observation teaches that each man has his own degree of power of resistance, or in other words, each specific temperament is associated with a specific diathesis. The nervous temperament with a mucous diathesis ; the sanguine temperament with the vascular diathesis ; and the fibrous temperament with the mucous fibrous diathesis.

Therefore, we study diathesis in order to know a man's power of resisting external conditions ; to know what man may live in a foul atmosphere ; what man may drink alcohol ; what man may expose himself to cold or heat without his health being injured. Diathesis teach us the way in which it is likely that a man may become diseased. It does not tell us what particular diseases he may have, but to what class of pathological changes he is liable.

History has stated that physiologists have immeasurably outstripped pathologists in the comprehensiveness of their views, and, therefore in the value of their results. For the physiologists have distinctly recognized that the basis of their science must include not only the whole animal, but the entire vegetable kingdom. The pathologist, however, rarely includes disease of lower animals in his teaching, and diseases of plants are almost entirely neglected. In the "History of Civilization" (page 411, vol. iii.), Buckle further states that until the diseases of animals and plants are included in our studies, the pathologist's conclusions will be little better than empirical, on account of the narrowness of the field from which his facts have been gathered. And I believe a similar decision would be given by most pathologists. I am every day more and more convinced of the truth of this view, and the Medical Press has done good service lately in calling attention to this defect. I believe that the practice of medicine will gain vastly by the study of comparative pathology. The great duty of the pathologist is to determine the causes of disease. It is for this purpose especially that a knowledge of diseases of animals and plants will be valuable. The inferior animals are exposed to comparatively few and to very general conditions ; man is exposed to these but also to numerous highly special influences all of which are capable of exciting disease. It is in man a most difficult task to decide *which of these many and different influences is the cause*, or the chief cause of the malady with which we have to deal ; for instance, a man whilst exposed to cold may be taking a large quantity of alcohol, and may be undergoing a great amount of fatigue, he is, perhaps, at the same time, suffering much mental anxiety : What share any one of these several very different conditions has had in bringing about his disease it is next to impossible to determine. Whereas, the problems presented by diseases of animals are far more simple, for they are exposed to fewer and to simpler conditions. There is yet another way in which we gain help from comparative pathology. Substances and changes which are pathological in man are sometimes physiological in lower animals and plants. A knowledge of healthy processes in the animal and vegetable kingdom may indicate how some pathological products are formed in man, and may show the conditions or causes which lead to their formation. In man it is often exceedingly difficult, even impossible, to observe the morbid changes in every stage of the disease, for at some periods of the complaints, persons rarely or never die. Animals, however, can be killed at any stage of their disease. The tissues in lower animals and plants are much simpler in their structure and arrangement, and, in consequence, a more satisfactory anatomical, microscopical, and chemical examination of them could be made. These are some of the advantages which the student of medicine may hope to gain by investigating the diseases of animals and plants. I will now briefly illustrate how much we may be assisted in this way.

In 1866, I examined the bodies of a number of persons who died of cholera, and I observed that with the exception of the morbid changes attributable to that disease, almost all of the bodies were healthy. This appeared to show that cholera attacks healthy persons much more frequently than diseased persons, and the same thing is observed in lower animals. During the Abyssinian war you will remember that an epidemic disease prevailed very extensively amongst the cavalry horses, and it was recorded that the healthy, strong, vigorous horses were those most frequently attacked. Further, the similarity in the action of disease in man and animal was further shown in this campaign when the horses were removed from the low lands, lying near the sea-shore of Abyssinia, to the high hills the epidemic rapidly disappeared. And experience has amply shown that man is, to a great extent, protected from cholera and yellow fever while he lives on greatly elevated positions.

It is well known that if a person's health becomes very much impaired, that ridges are sometimes formed across the nails of his fingers ; and Mr. John Hancock, a distinguished naturalist in the North of England tells me that if a hawk be badly fed and falls into bad health, his wings appear to stop growing, and a ridge is formed round the bone at the end of the wing, The same thing (that is a temporary arrest of growth), is evidenced by the circular markings which show the yearly growth in our exogenous trees.

The evil effects attending domestication are witnessed in plants and animals as well as in man. Statistics have demonstrated that persons living in large towns, working in doors, are very much more liable to become consumptive than persons living in the open country. And horses and other animals appear to be almost exempt from consumption while living in the fields, but they very frequently suffer from phthisis when they live in stables. Horticulturists have informed me that their plants living in hot houses are more liable to disease than the plants growing in the open air. Dermatologists know that if a debilitated person contracts scabies, the attack is often severe, and sometimes very much more difficult to cure than scabies occurring in a healthy person.

A similar thing is observed when badly nourished animals and plants are the subject of parasites. After these brief illustrations, I return to my main topic.

You are required to study the changes which go on in health in the tissues, in order to understand the nature of pathological transformations. You will examine how new cells are formed in healthy mucous membrane in order to understand how they are produced when that mucous membrane is inflamed. You learn how bone is developed in order to appreciate how an osteoid tumour is formed. And you will perceive that in inflammation of a mucous membrane the crowds of new cells are formed by a similar process to that which is observed in the production of new cells in healthy mucous membrane. Some differences are observed. They are differences of degree ; they are due to the disorderly and successive and rapid growth of the cells in inflammation ; and their orderly growth and slower succession in health. Pathological changes are modified physiological processes.

Pathology also includes a study of the order to be witnessed in the succession of the phenomena of diseases. The presumption is that all morbid processes run a defined course, and in some we can say what that course is. Many diseases continue a definite time, their outset, their exacerbation, and their termination are marked by distinct periods ; and, although a large number of diseases have no definite period of duration,

many of them present a determinate order in what I may call their great events. The diseased action may go on week after week, and the length of time that it lasts may be very uncertain; but each of the differing morbid processes that constitutes that disease has its own place in the series. In phthisis some pneumonia or so-called tubercle may occur in the upper parts of the lungs. There is a local increased cell growth, and a consequent accumulation of cells. These morbid processes may cease, and the products formed or effused, may undergo degeneration and remain lifeless matter in the body. Afterwards there may be a period during which the patient gains flesh, recovers appetite, and keeps well. Health may continue for a few weeks, a few months, or many years, and then the morbid processes may recommence. Periods of ingravescence, and of health, may alternate for many years.

Mr. Paget, speaking of granulated wounds, says that blood gradually ceasing to flow from the surface of the wound, one may still see some thin tinged fluid oozing from it slowly. As this fluid becomes paler, some of it collects like a whitish film, or glazing, on the surface. This glazing increases, and it is the prelude to the formation of the granulations; and while it is going on, and for some days afterwards, there is a period of calm which may continue from one day to ten days or longer.

Order in sequence is evidenced in each of these diseases. It is most readily detected in acute diseases, but it may also be observed in chronic affections. If a number of persons suffering from chronic Bright's disease are carefully watched, the rule is that we observe cerebral phenomena prevail at one stage of the disease, gastro-intestinal, cardiac pulmonary, or hæmorrhagic phenomena, at other periods. This succession of events is characteristic of chronic Bright's disease, and it occurs in hundreds of persons, every year, and in many countries. These facts clearly show that *there is a definite series* of changes—*an order* which is distinctive of the disease. Such an order is known as the "natural course of disease." It is desirable that every practitioner of medicine should be familiar with the course that every disease follows. He should accurately know the order in which the phenomena may occur for, if he does not, he will not be able to judge of the progress of his patient nor to foresee the possible emergencies. Without this knowledge, he will be unable to be sure whether the treament adopted has benefited or has injured his patient.

By studying morbid anatomy and pathology the student knows how persons die and how diseases are to be cured. Pathology reveals that during restoration to health there is a gradual substitution of physiological for pathological processes. An abandonment of pathological order for physiological order. To this rule I know of no exception. An organ diseased may never regain its original structure or dynamical condition, because a part of it has been altogether destroyed; but all the living tissues will return more or less closely to their normal life. If mucous membrane is injured, we observe that new cells grow from the parent cells to replace those which had been destroyed. Albumen is taken from the blood to supply nutrition to the newly-growing cells. And the same kind of processes go on, no matter what is the nature of the injury, provided that the membrane be not destroyed. The truth of this observation is shown also by what takes place after inflammation of serous membranes. If we examine the adhesions which are the remains of inflammation, we find that they contain the tissue elements of normal serous membrane. There is defective development and some parts have undergone degenerative changes, or, in other words, they are dead. The inferiority of these new structures to those proper to the body is due to the adhesions being rapidly developed. We know that all things which are developed quickly are apt to die proportionately easily. Durability and slow growth go together. In fractured bone the injury is repaired by physiological fibrous tissue or by cartilage. Similar evidence might be derived from disease in every part of the body. *In giving drugs, therefore, for the cure of disease, all we can hope to do is to promote physiological actions.* The pathologist knows that remedies will not, and cannot, excite any process unlike any normal operation of the body, unless it diminishes or destroys the life of the tissue. Seeing, therefore, that injuries and diseases are cured by actions physiological, the practitioner of medicine employs those conditions which promote the required physiological processes. Drugs, therefore, are only some of the many conditions which the practitioner must summon to his assistance when treating disease. The body both in health and disease requires new matter from without to keep up the forces within. Force may be given by heat, by light, by air, food, or by physic; and observation is teaching every year that persons may, when thus supplied, recover from very severe diseases without the aid of medicine.

It is admitted that a person may be a pathologist and yet not be a skilful physician, but I do not think that any person can know how to properly treat disease if he is ignorant of pathology. For the treatment of disease is determined by a knowledge of the direct and indirect causes. This has long been recognised. Cullen wrote*—"The cure of diseases is chiefly and almost unavoidably founded in the knowledge of their proximate causes." Pathology teaches which are the causes, and the manner in which the body remedies the evil.

The student of medicine has also to learn how to recognise disease. He gains the knowledge by observing the symptoms of disease. I strongly recommend you to labour to observe things accurately. An uncultivated person is very apt to think that it is an easy thing to make a correct observation. It is, however, extremely difficult. Observation requires great attention, and so many things have to be considered, and there are so many sources of fallacy, that few men are capable of making accurate observations; and but few complete observations have at any time been collected. Every student, therefore, should educate his senses; and, if he be a careful man, he will soon admit that it is not easy to observe correctly with untrained eyes. Two distinguished dermatologists may examine the skin of a patient, and be unable to agree as to whether there is too little or too much pigment in it. It is equally as difficult to judge a thing with the fingers. Two skilful surgeons may differ in opinion as to whether a tumour is a sac full of fluid, or an elastic solid substance. Clinical instruments are great aids in the diagnosis of disease, and they become of more importance day by day. I therefore recommend you strongly to learn how to use skilfully the thermometer, the laryngoscope, the microscope, the ophthalmoscope, stethoscope, and others. The student should, above all things, train himself to think—to draw his conclusions logically. Remember, it is the great thinkers who are the real benefactors of the world.

In examining a patient, try your utmost to be earnest, sincere, and very painstaking; I have heard persons remark Mr. So-and-so is exceedingly clever, he is very sharp, and at once sees what is the matter with a man. However much this may impress an uneducated mind you will soon discover that it is mostly impossible to make an accurate diagnosis, unless the patient is very carefully examined, to discover the whole of the existing facts. Often a medical man diagnoses a particular disease by satisfying himself, after systematic examination, that no other disease is present to account for the phenomena.

There is another branch of medicine which has made great advance during the last few years—the art of preserving health—that is, of preventing diseases. It has gained greatly in popular estimation. Public opinion realizes that it is more economical to prevent disease than to cure it. The medical mind recognizes that a large proportion of contagious or infectious diseases are avoidable. Many acute pathological changes are preceded by degeneration in the tissues of the body.

Chronic diseases are very often the result of decay in the tissues which can no more be cured than an old oak tree can be made young again. The cells and vessels of the tree and the fibres and cells of the man have exhausted their life. All these things teach the medical man that a large number of diseases are incurable, because the diseased tissues are more or less molecularly dead. He is required, therefore, to find out the earliest indication of failing health, and to instruct the patient how he is to live in order that he may arrest or retard the decline. To preserve health we must obviate the causes of disease. And here pathology comes to our assistance. It assists us in determining the conditions which are acting and exciting disease. In guiding a person how to prevent his health failing, a medical man's knowledge and skill is most severely tested. For we are bound not to cause the patient any needless anxiety and suffering, and we must not allow him to fall into incurable disease and death without pointing out to him how it is to be avoided. The physician should try to detect the slightest failure in function and the earliest indications of tissue decay. Many patients come for advice complaining of wandering pains, of slight indigestion, or some other apparently trivial affection, and we find that these ill-defined symptoms are the earliest indications of tissue degeneration. Many

* Works of William Cullen. P. 475. Vol. 1.

agitated nervous ill-regulated children are the future victims of hysteria, epilepsy, or some other mental brain disease. This is a section of medicine which must amply repay any amount of labour in research, and, as it progresses, mankind will become conscious that the advance of medical knowledge is contemporaneous with the world's improved development.

Vast numbers of children living in our large towns are the offspring of degenerate parents and grow up sickly. They are but natural products of the noxious influences which surround them. And no Education Bill can accomplish what all education should do, that is, develop the man unless it is accompanied or preceded by the enforcement of sanitary laws. Brain function, mind and brain, are inseparable, and to raise the qualities of one, we must take proper care of the nutrition of the other.

I have endeavoured to show how important it is that every student should examine the influences which man inherits from his parents and the influence of the conditions which surround him. They are the two factors of health and disease, and the cure, alleviation, and the prevention of disease is to be regulated by attention to each of these. The phenomena of health and disease are the certain results of antecedent conditions. When we observe what is passing around us how the agriculturist by taking advantage of inherited influences and of the actions of external objects develops and rears animals to serve the purposes of man; how the horticulturist by similar means, develops and modifies the colour, the shape, and beauty of his plants and flowers to educate and gratify the mind of man. We perceive great principles which the medical practitioner may some day use to prevent and relieve the sufferings of his fellow beings.

We see that the physical sciences are making great progress, and it is our duty not to allow medicine to lag behind. We must avail ourselves of every kind of knowledge which tends to disclose to us physiological and pathological truths.

Abstracts of Lectures.

UNIVERSITY COLLEGE.

The Introductory Lecture at this hospital was delivered by Mr. Berkeley Hill, who, having lately returned from the Seat of War, devoted much of his lecture to that subject. Having described the nature of the receptacles for the sick, the Lecturer proceeded to discuss the question of transport, which, since the American war, had made, through the addition of volunteer aid, such marvellous progress in its organization. As late as the wars of the first Republic, the only means for the sick and wounded were the baggage-carts and the services of soldiers from the ranks when they could be spared. The first Baron Larrey, while attending the Republican armies on the Rhine, was the first to devise a system of special carts, the wounded being in the front, for at that time the moveable field hospitals were one league in rear of the attack, consequently twenty hours always elapsed before the wounded were got into hospitals. This was the commencement of the system of ambulances which are now employed by the French army, and had, with many modifications, been adopted by all other military nations. It would perhaps be as well to explain the different meanings attached to the word ambulance. Abroad it signified a moving hospital, that was, a corps of surgeons, attendants, stores, waggons, horses, &c. In England the term was frequently but erroneously applied to the waggons for conveying the sick from place to place. In his remarks he should use the word in the continental signification. In the hands of the French the ambulance system frequently broke down. The direction and supply of the material, waggons, horses, stores, &c., were entrusted to the Intendance, a department that managed the commissariat, transport of supplies of all kinds, even the convoy of ammunition, and consequently had far too much to do to allow it to meet sudden emergencies in the medical requirements of the army. Again, an invariable consequence of this centralization was a general breakdown when the army to which it was attached suffered defeat, as in the present war. The French Intendance had been utterly unable to assist in the conveyance of their wounded, who had been left entirely in the hands of the Germans, and of the few volunteer French and foreign ambulances that had been able to get to the battle-fields. Nay, even when the army was in a friendly country, or victorious in a hostile one, the Intendance had been unable to meet even trifling demands, when of an unexpected kind. For example, the Emperor Napoleon III., at the outset of the Italian campaign of 1859, decreed that the baggage of the officers should be carried for them by the Intendance. This could only be done by taking the cattle for that purpose, which were attached to the hospital field waggons. It was therefore not surprising that a few days later than the date of this decree, they learnt that for four days after the battle of Montebello, May 20, 1859, 800 wounded were fed entirely by the charity of the inhabitants, the Intendance having failed to bring supplies and surgical necessities of all kinds. In short, had the French been fighting in a thinly-inhabited or hostile country, their loss from sickness, even great as it was, 193,186 men having been sent to hospital during the short stay of the French army in Italy, would have been largely increased. But far more disastrous than this was the condition of the English army in the beginning of the American war, and of the Americans in the beginning of their last war. The English army landed in the Crimea with a means of transport for the sick of one pony per regiment, and ten canvas stretchers; yet the principal medical officer of the Crimean army stated in evidence before the sanitary commission that he had before the campaign asked for 42 waggons, 336 canvas stretchers, and 672 men for his hospital corps. He received in return three waggons, without harness, horses, or drivers. In consequence of this neglect our army was delayed two days after the battle of the Alma, collecting and carrying the wounded down to the shore, and many lives would have been lost had not the French lent their litters and mules to transmit our sick and wounded to the shore, where the crews of the men-of-war conveyed them to the hospital ships. Again, after the battle of Inkerman, the French lent the English 500 mules to bring in the wounded, and to their aid the English owed it that the wounded English were on that occasion in bed and attended to by six o'clock of the evening of the battle. But the want of a pre-arranged system of transport and machinery for receiving the sick and wounded was most grievously felt in the early battles of the American war. Mr. Hammond, afterwards the American surgeon-general, writing eight days after the battle of Bull's Run, told his superiors that 600 wounded remained on the battle-field, where many poor fellows had already died of starvation. Again, Dr. Agnew, a member of the American Sanatory Commission, estimated that 500 lives were lost after the battle of Antietam, Sept. 17, 1862, for want of proper transport; also after the battle of Manassas, Sept. 7, 1862, 2,000 wounded lay from Saturday to Wednesday on the field without food or water; the surgeons even were starving with their wretched patients. The news of these and similar horrible mischances acted upon the Americans of the Northern States as thoroughly as the news of the Crimean disasters acted upon Englishmen. A volunteer association was formed by the Government, endowed with abundant means for the succour of their sick and wounded soldiers from the contributions of all classes of their fellow countrymen. From the foundation of this leading volunteer association and its satellites, order and plenty were quickly provided for the soldiers and the sick and wounded. The volunteer aid and transport was so perfectly organised that on many occasions, notably on that of the battle of Fredericksburg, Dec. 13, 1862, the carts and agents of the volunteer aid societies were in the field of battle under fire several hours before the ambulance carts of the regular forces reached the scene of action. These volunteers carried off the wounded as they fell to hospital tents, where their injuries were dressed and their wants were supplied. Again at Gettysburg, in July, 1863, one of the battles which decided the war, where 20,000 Federals fell in the three days of the battle, and at least as many Confederates, the agents of the Sanatory Commission were again so close to the moving columns with their supplies and assistants, that by the day after the fighting ended, every wounded man was in hospital and his clothes changed. The transport and aid of the sick and wounded was developed to a higher perfection by the Americans in their war than by any other nation. In the present war many of their expedients had been copied, notably that of the arrangements of hospitals for reception of the wounded away from the scene of war, and again with regard to the hospital trains, &c., which formed part of the means of transport, which he would describe. The German system of transport was two-fold—

that organised by the military department, and the volunteer transport, which, though recognised and aided by Government, was for its funds entirely dependent upon the contributions of individuals. With regard to the military system of transport, each army corps was considered a complete army, and was supplied with equipments of every kind to enable it to act independently or in concert with other army corps, as might be advisable. Therefore each army corps had its medical staff of twenty head-surgeons, with proper proportion of assistants, dressers, carriers for the wounded, drivers, horses, litters, stores, waggons, some to convey the wounded, others to convey surgical stores, water, &c. The wounded received attention to their most urgent wants without delay, for each soldier carried on his person a bandage and a piece of lint, which the sick bearers were taught to apply, as well as put in force means of stopping loss of blood should that be necessary, before the wounded man was raised from the ground. The sick bearers were likewise instructed in the best way of carrying the man according to the nature of his wound. With these precautions the wounded were taken to the surgeon, who was close to the scene of action; he examined the wound, applied splints or what dressing was necessary to enable the man to reach the field hospital, and inscribed on a piece of paper provided for that purpose, the nature of the injury and what had been done to relieve it; thus when the man reached hospital needless examination was saved. All these officials were, in time of peace, carefully drilled in their duties, and had as their sole charge the collection and attendance of the wounded in battle, or the sick who fell out in the march. Thus the combatants not only fought with better heart, knowing that if disabled a body of skilled persons would come at once to their rescue, but they had no excuse to leave their ranks at the critical moment of a fight to carry a wounded comrade to the rear. The wounded or sick being safely disposed of in the field hospital, the next step was to restore them to such a condition that they could be despatched to the permanent hospitals in Germany which were ready to receive them. This was also most advisable, because the field hospitals were rarely, if ever, supplied with the best means of repairing injuries, nor were they salubrious hospitals. It was also necessary to clear out these primary hospitals to make room for fresh cases constantly coming from the front. Indeed, the heavy slaughter of the recent battles was far greater than the field hospitals could meet, and thus the neighbourhoods of the battles had been crowded with wounded and dying in a condition almost as bad as if no provision whatever had been made beforehand. Again, the necessities of the campaign required the staff of surgeons, with their assistants, to leave their wounded and follow the marching columns to be ready for the next engagement. When all was ready the patients were fed, the wounds were dressed, and their wants supplied as well as the resources of the field ambulance they were about to quit would allow; and they were placed too often in carts of the rudest description, in which they travelled, whatever might be the weather, to the railway station. Here a corps of the volunteer assso-ciation was ready to receive them, to lift each man from his waggon, to carry him to the sheds were the surgeons and dressers quickly changed his dressings—often sorely in need of it. In this way enormous numbers of wounded and sick had reached their Fatherland. Besides railway hospitals, sixteen trains of the Rhine steamboats had been fitted up as hospitals, and had conveyed many thousands down the river to cities on its banks in the easiet manner possible. The Lecturer having alluded to other organisations, proceeded to say that the Crimean struggle was the occasion for the noble efforts of this country, and the generous devotion of Miss Nightingale, but no organised society sprung up in that national crisis, and the need for volunteer aid having passed away the nation no longer interested itself in the matter. In the late struggle in the United States, a volunteer aid association—the American Sanatory Commission—grew up, which had a career of the utmost success. In the three years of its existence it collected no less than two and three-quarter millions sterling, and saved, it was said, 100,000 lives. The progress of surgery during the last twenty-five years had not been without effect in modifying the treatment of injuries received in warfare. During that period most important changes in the art and practice of surgery had been established. The general use of anæsthetics was perhaps the most striking change. When the Crimean war commenced, the opinion of military surgeons was divided on the expediency of using it in very severe injuries, it being supposed by some that the chloroform diminished the chances of recovery when the patient was prostrated by the shock of a severe injury; while, on the other hand, the sharp agency of the amputating knife was deemed useful to rouse the sufferer from his exhausted condition. This belief was rapidly exploded, and in the English camp at least the use of chloroform became universal in all operations of any magnitude. In the present war the bounteous supplies contributed by charitable persons had also enabled the use of chloroform to be very general, and the cases where it was not used were very few. The Lecturer gave some practical advice in reference to overcrowding in hospitals, and spoke in high terms of praise of the improvement which the English Government had made in this respect since the Crimean war. Addressing the younger students, he expressed a hope that by attention to work they would succeed in obtaining a prosperous career.

ST. GEORGE'S HOSPITAL.

The Introductory Lecture at this hospital was delivered by Mr. B. E. Brodhurst, F.R.C.S. Having offered a hearty welcome to those who were entering upon their studies, and to those who had returned to commence another session of earnest work, he congratulated the first, not only that their time had fallen so auspiciously as at the present moment, when great and important and most advantageous changes were taking place in the profession, but that they had selected St. George's Hospital as the place where their student life should be passed. He had no hesitation in saying that no hospital and medical school in this country could offer the student so many and great advantages as St. George's did at the present moment, and he said it the more freely not having himself been a student at St. George's Hospital. Not only were there great advantages of which they would partake, but they would become part of a body, he might say, to which belonged some of the names most famous in medical science, such as Cheselden, Baillie, Heberden, John Hunter, Cæsar Hawkins, Everard Home, Robert Keate, Benjamin Brodie, Frederick Chambers, Thomas Young, George Babington, James Hope, Robert Lee, besides a host of others whom he would not then mention, but who would soon become familiar to them as household words. Great changes were taking place in the medical profession. A medical bill was introduced during the last session of Parliament by the Government, which, having passed through the House of Lords, was subsequently withdrawn in the House of Commons that a new and amended bill might be introduced during the next session. This bill would require that every medical practitioner should obtain a licence to practise both in medicine and surgery. Thus a new qualification would be required. At the present time there were no fewer than 19 licensing bodies for the profession in the United Kingdom. Some of them conferred the licence to practise after very severe examinations, and again, there were others by whom a licence was conferred without examination. But what could the public know of the relative value of these several licences? It was known that the candidate had obtained a licence to practise, but it was not known what test had been applied to ascertain the amount of his knowledge, and whether the licence had been obtained in London, Oxford, Cambridge, Edinburgh, Dublin, Lambeth, or elsewhere. It was alone known that a qualification had been obtained, but it was not known what were the respective merits of these various diplomas. Further it was found that a certain number of students were educated in one division of the kingdom, and that they obtained their qualification in another division. This happened especially in the English and the Irish schools. It was obviously unfair that the same privileges should be extended to the idle as to the diligent student—that he who fitted himself only to pass an inferior examination should be placed by the public on a similar footing with him who had perhaps competed for and gained honours in the highest examination. It was the object of the Bill he had referred to to compel every student to obtain a licence in medicine and surgery, by submitting himself to examinations which should be of a precisely similar character in each division of the

kingdom. Everyone who desired to practise under the English law must obtain this licence, for without it registration would be impossible; but no one would be allowed to practise who was not registered, and thus there would be one portal only to the profession. Having obtained his licence to practise the licentiate would proceed to accumulate honours, or he might remain content with his licence. One thing alone would be made imperative, namely, the licence to practise. This would enable the holder to compete for Government appointments, or to enter upon private practice. The examination for the licence would be a severe test of knowledge, and would include, after an examination in common preliminary education had been passed, chemistry, physics, anatomy, physiology, materia medica, medical and surgical anatomy, pathology, state medicine, and the several departments of practice. In quoting the example of the First Napoleon, he reminded every student that by dint of hard work he might do what Napoleon did for himself. It was not genius that was required to insure success so much as honest hard work, such constant and continued work as left the subject indelibly stamped upon the mind—unalterably possessed by its owner. He advised those who had determined to throw in their lot with the medical profession to pursue their calling with brave and earnest hearts for the more difficult the task the more noble it would be to overcome it.

CHARING-CROSS HOSPITAL.

The Introductory Address at this hospital was delivered by Mr. Henry Hancock, Vice-president of the Royal College of Surgeons, who commenced by alluding to the late Dr. Chowne in the following words:—The grave has just closed over one of the most respected members of our profession—the oldest medical officer of our hospital: the late consulting physician, Dr. Chowne. Attached to the hospital almost from its foundation he was always a painstaking, kind-hearted colleague, a firm and stedfast friend, and a high-minded honourable man. May those who hereafter may have to allude to our deaths be able conscientiously to say the same of us.

Having alluded to the war and welcomed back old students, he said to the new ones: Let me also offer a welcome to those about to enter our profession—a profession of extreme responsibility, anxious thought, and unceasing labour. Mr. Abernethy, upon a similar occasion as the present, welcomed his commencing students with "God help you all!—what will become of you?" The answer to this question depends upon yourselves, and is comprised in the single work, "Work." If you will work you will do well; but rest assured to no other class of men does the parable of the ten talents apply more directly than it does to students of medicine. If you are content to idle away your time, to fold your single talent in a napkin, depend upon it it will be taken away from you, and you will terminate your career in disappointment and disgrace.

Passing to a subject that has been fully discussed in our columns, he said, I need scarcely remind you that the present year, 1870, has been a very eventful one in the annals of medicine. Measures of a most revolutionary character have been considered and discussed, and although in abeyance at present, will in all probability be sooner or later adopted.

During the early spring the College of Physicians, the College of Surgeons, and the Society of Apothecaries, inaugurated a scheme for conjoint examination, having for its object the diminution of the number of examinations as at present required, and the substitution of a single portal of admission into the profession; the diploma of having passed this examination to confer the right of practising and registering upon the holder, as well as the right of selecting one of the three corporations of which to become a member. When this scheme was so far matured as to be almost ready for submission to the Secretary of State for confirmation, it was unceremoniously set aside by the Government, who, ignoring the corporations altogether, introduced a Medical Bill of their own, by which the several corporations were deprived of their powers of granting diplomas to practise, and all power of regulating the course of study as heretofore; in fact, transferring some 20,000 of the most thoughtful and intellectual men in her Majesty's dominions to the caprice and control of the Privy Council, or, in other words, to its irresponsible medical adviser for the time being. This Bill, which unsettled everything and satisfied no one, after being twisted and distorted to meet contending interests, has been withdrawn; but there is no doubt that important changes will take places, and it is my duty to consider how far these changes will influence your future course of study.

You, or at least the majority of those present, have already broken ground by passing what is termed the Preliminary Examination. Here again the year 1870 has proved most eventful. The last examination at the College of Surgeons was most disastrous. Of 229 who went up, only 106 passed, and 123 were deficient in the amount of knowledge required and were rejected, being thrown back in their professional studies for above six months, and subjected to no slight addition to the expense of their education. This result appeared to me so lamentable and unsatisfactory that I have taken some little pains to ascertain the cause, in the hope that, by pointing out the subjects in which these gentlemen failed, I should do good service by directing the attention of those engaged in tuition to the matter, that they might take measures that an occurrence so unfortunate, and redounding so little to their credit, should be prevented for the future. The subjects examined upon are arranged in two classes: compulsory and optional. The compulsory class embraces Reading, Dictation, Arithmetic, Geography, Grammar and Composition, History, Euclid, Algebra, and Latin. Of the 123 who failed, 71 failed in Algebra; 52 in Latin; 31 in Euclid; 21 in History; 17 in Grammar and Composition; 12 in Arithmetic; 6 in Geography; 1 in Dictation; 1 in Reading. The class of optional subjects comprises: Greek, French, Mechanics, Chemistry, Botany, Zoology, and German. In Greek, 2 failed out of 69; in French, 15 out of 84; in Mechanics, 11 out of 28. In Chemistry, Botany, Zoology, and German, there were no rejections; although 93 went in for Chemistry, 5 for Botany and Zoology, and 5 for German. Undoubtedly, several among those unfortunates may have been idle and neglectful; but, on the other hand, when we find so large a proportion as 54 per cent. rejected, we can scarcely arrive at any other conclusion than that the existing system of education in many parts of the country is below the requirements of the age, and that in neglecting to make themselves acquainted with what is required from pupils at these examinations, teachers are guilty of dereliction of duty, and of great injustice to those entrusted to their care.

As may readily be imagined, every attempt to raise the standard of education has been followed by a diminution in the number of medical students, and, consequently, of medical practitioners. From the year 1831 there has been a regular increase in the population of England and Wales, say in round numbers, of 2,000,000 every ten years. Thus, in the ten years from 1831 to 1841, the increase was 1,983,000; from 1841 to 1851, 2,019,000; from 1851 to 1861, 2,174,000; and it will not be unfair to calculate a similar proportion of increase for the ten years between 1861—1871. It may not be uninteresting to inquire how far the profession of surgery has kept pace with this increase; and for this purpose I propose to take the average number of diplomas issued by the College of Surgeons during each of these decades. To begin with the decade 1831—1841, the average was 520 per annum. In the next, or between 1841—1851, although the population had increased 2,000,000, the average of diplomas issued by the College fell from 520 to 430 per annum. In the next decade, between 1851—1861, the average rose from 430 to 501; whilst in the decade about to close it has fallen as low as 371. So that, notwithstanding an increase in the population of 8,000,000, and taking the College of Surgeons as the standard, the average of men entering our profession is 149, or nearly one-third less per annum at the present time than it was forty years ago. Undoubtedly the development of railroads, the still greater development of engineering in all its branches, and the state of the mercantile world during this period, have greatly influenced this result; but there is no denying that it has also been influenced in a great measure by the higher standard of education required by the examining bodies.

The lecturer then passed in review the subject of study that first engage the student—referred to the improvements lately made at the hospital, and the changes in the school—and closed by urging all so to work as to add lustre to *Alma Mater*.

MIDDLESEX HOSPITAL.

Dr. Cayley delivered the Introductory Address at this hospital. He stated that Mr. Paget, of St. Bartholomew's Hospital, had lately published some statistics which might be taken to afford a fair general average of medical students. He had been enabled to pursue the career of one thousand medical students, and the results thus brought out were both interesting and instructive. In the first place, ninety-six, or nearly ten per cent., left the profession. With those they had nothing further to do; but it might serve to remind them that if so many retired from it on the threshold, the task they had taken in hand who had remained in the profession was no light one. Next, 128 died either during their pupilage or shortly after commencing practice, twenty-five of whom succumbed to diseases incurred in the discharge of their duties. The next class on the list was one still more gloomy, for it was found that fifty-six out of the thousand entirely failed, some from unavoidable misfortunes, most, it was to be feared, from their own misconduct. Turning to the brighter side, they found that twenty-three achieved distinguished success, and sixty-six considerable success. These, he need hardly say, were very large proportions, for distinguished success could never be the lot of more than very few. Those who achieved a fair amount of success included 507, or upwards of half the whole number; and this degree of success was probably in the power of almost all to attain to. Lastly, they found that 124 attained to a very limited success. The lecturer then passed on to consider the nature of the profession upon which the students were about to enter, and strongly urged that a knowledge of physics and chemistry was an essential part of the science of medicine. In these respects a great reform had doubtless now begun, and it would not be long before that would cease to be considered a finished liberal education which left a man ignorant of the nature of the air which he breathed, of the water he drank, of the food he ate, of the earth on which he trod, and of the structure and functions of his own body. Though placing a great stress upon the importance of studying subjects practically, nothing was farther from his intention than to underrate the value of systematic lectures. Unfortunately, there was always a small minority of students who were incapable of raising their minds to any higher idea of their profession than as a means of earning a livelihood with as little trouble as might be, and who therefore would confine their efforts to obtaining a minimum of the necessary qualifications, or whose wills and normal purposes were too feeble to resist any passing gratification for the sake of those higher objects which were alone worth striving for, and who, as they were insensible to higher motives, could only be induced to work by the low one of fear—who studied, in fact, a liberal profession in the spirit of slaves. Dr. Cayley proceeded to refer to the modern objectors against the utility of the medical art, and who had arisen chiefly in their own ranks. These urged that apart from mere surgical or mechanical appliances the power of controlling disease by the use of remedies was almost null, and that by attempting to interfere they really did more harm than good. Hence had arisen what was called the expectant school of medicine, in which the physician looked on as an intelligent spectator at the contest between the disease and the constitution of the patient, but without departing from a position of benevolent neutrality. He concluded by counselling the students that when their period of training in the hospital was over they might indeed be well armed and equipped for the contest with disease and death.

ST. MARY'S HOSPITAL.

Mr. Gascoyen delivered the Introductory Address, taking for his subject the present system of Medical Education. Whilst admitting that great improvements had been made in the course of medical instruction, and in the examinations, during the last few years, the lecturer thought that much more was needed in both before they were made as perfect as they might easily be. He congratulated the Profession that at last there seemed to be a prospect of obtaining a similar course of instruction, an equal examination, and an uniform fee, for students throughout the three divisions of the Kingdom; and stated his opinion that examining boards chosen from the present licensing bodies, to conduct examinations and grant diplomas, would be preferable to a board appointed by the Privy Council. Although strongly advocating this change, he believed that many of the present examinations were fairly conducted, and were not only fully up to the capacity of those examined, but even beyond them; and that the students, as at present prepared, were incapable of passing a higher test of proficiency. He thought that the students as a body were not so well prepared for their examinations, or for their exigencies of practice, as formerly, and attributed this to three main causes.

The *first* of these was the deficient general education of so many of the students; and the habit, which was acquired at school, of neglecting elementary instruction, for the sake of varied and superficial attainments, created an indisposition to master the ground work of medical science, and operated most injuriously upon the students.

The *second* reason was the very insufficient time allotted to the study of medicine, whilst the number of collateral subjects and the excessive detail crowded into this limited period, still further prevent adequate attention being paid to the most important.

The *third* reason was to be found in the scepticism in all matters medical which now pervades the Profession, and which questions the treatment of the student as it does that of the patient. It has unsettled the student by questioning the utility of everything connected with our present system of teaching, and caused him to slacken in his work. Whilst casting doubt upon the curative value of drugs, he has come to regard the medicinal treatment of patients as a secondary matter, and to act as if fully impressed with the truth of the doctrine, that all will come right with waiting. It has brought about a state of mind similar to that expressed by one of Dickens's characters, that "There is nothing new, and nothing true, and it don't matter," which is anything but an incentive to work.

To meet these difficulties the lecturer proposed that the preliminary examination in arts should be made at least equal to the matriculation examination of the London University, as anything short of this would be insufficient to obtain an educational superiority on the part of the Profession. To require every student to pass an examination in chemistry, botany, comparative anatomy, and natural philosophy, before he joins a medical school; and that he be at least eighteen years of age. To demand four full years' attendance at the school and hospital, and at the expiration of these to pass one other year in active professional work as assistant to a practitioner, house surgeon at a hospital, &c., before he be allowed to register his diplomas, and practise on his own account. A clinical examination was also insisted upon as a *sine qua non*.

The waste of time, money, and energy, caused by the support of so many schools of medicine, was commented upon; and their amalgamation advocated into *two* medical colleges, where the professors should be paid such incomes as would insure the best available teaching power, and attach them permanently to their chairs; whilst the several hospitals could be used for clinical purposes as is now done.

The system of double examinations was then considered, but although acknowledged to be far superior to the former plan of single examinations, the lecturer doubted whether as yet they had been of much real service, in consequence of the tendency they have to split up the student's time into short periods, during which everything is sacrificed to those subjects in which he is about to be examined, so that when the Primary Examinations have been passed, the time remaining is far too short to gain more than a hasty shallow knowledge of disease and its treatment.

The speaker expressed his strong belief in the value of lectures, and in the importance of retaining an official curriculum as essential to the welfare of the student, his friends, and his teachers; and gave reasons why he thought the practice of requiring certificates of attendance should be continued.

The aims of medicine were briefly touched upon, and a judicious use of drugs advocated, instead of the purely expectant and stimulant treatment; and the address was concluded by offering encouragement and advice to the students, and pointing out to them certain faults which seem to be handed down from one generation to another.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

The Introductory Address at this School, was delivered by J. C. Brown, D.Sc. (London), F.C.S., lecturer on chemistry and toxicology. Having welcomed new and old students, and those who, though not students, showed by their presence that they took an interest in medical education, he referred to the practical tendency of reform in medical education, and urged the students to pay careful attention to all the systematic courses of lectures, with the view of seizing upon the principles and laws of each branch of science which they studied rather than make themselves profoundly acquainted with all the details of one particular science. Their knowledge must be acquired with a view to the cure of disease. They must not only know but act, and they must know in order that they may act. Therefore, if they had any concern for the welfare of those who would be committed to their charge, they must gain all the knowledge they could and store it up not merely for the day of examination, but for life-long use. The students were advised to aim at the highest degrees in medicine and surgery, not so much on account of the honour and position which they would bring, but rather on account of the stimulus which they gave to the acquisition of a sound and liberal education. The great facilities which the Liverpool school afforded for gaining a high class education, both in practical and theoretical subjects, were pointed out, and the improvements which had been made during the last year enumerated, The Materia Medica museum had been entirely renewed, the Library had received a large number of new books, and the Pathological museum had been increased by the transfer to it of the collection which belonged to the Liverpool Medical Institution. A catalogue had been drawn up and printed in order to facilitate reference and increase the usefulness of the museum. A new room had been built to increase the Laboratory accommodation, and new apparatus was continually being added to the chemical department. In connection with the Chair of Physiology, a Demonstrator of Practical Physiology had been appointed, and it was to be hoped that ere long a physiological laboratory would be provided. Other towns had their universities and their richly endowed schools, while in Liverpool a comparatively small body of men, with very little assistance from without, had been doing all the work of a university, so far as the facilities of medicine and science were concerned; and he though that the merchants and moneyed men in the neighbourhood should aid, with their money and their influence, in fostering an institution which would be of incalculable service, not merely to the present, but to future generations.

At the conclusion of the lecture the prizes were distributed, and in the evening, the Annual Dinner went off with its usual success.

THE MANCHESTER ROYAL SCHOOL OF MEDICINE.

The lecture introductory to the Session 1870-1 of this school was delivered to the students, on Monday week by Mr. Leo. H. Grindon, the lecturer on Botany.

Mr. Grindon, in the course of his lecture, said that the popular superstition regarding the medical man was that he was a species of conjuror, armed with an antidote to every possible form of malady, and that his province in the world's community was simply to wage war with disease. Not of this kind was the truth. His high and essential duty was to preserve things in the condition nature intended for them; to do his utmost to vindicate the grand idea of vigour; aiming, without doubt, on the lower ground, to mitigate suffering *per se*, but holding at the same time to his first and highest principle, which was, to give no opportunity for disease and suffering to enter. It was in the abiding by this great and fundamental law, preserving from within, rather than assuaging on the outside, that the men of vigour showed themselves symmetrical with nature, and to be the exponents and exemplars of all true and noble medical science. The *beau ideal* of medicine was the perfecting of vitality; so ordering the household, that was to say, that disease should find no point of entrance. That he was right in his estimate of the true design of medicine was proved by the immense change that had of late years supervened on old methods of practice. Every day was more strongly manifested the conviction of thinking men that to drench with conventional mixtures, to bombard with pills, and to drain away whole pints of the crimson sap, was really only calling upon nature to get over an additional difficulty—the difficulty imposed on her by those druggey barbarisms, and by the vampire of blood-letting; and that the true future of medicine would be found, not so much in the cure of disease, as in its prevention. They might congratulate themselves that the day had gone by when it could be said in grim pleasantry, at the close of a coroner's inquest, that the verdict, instead of being "Died by visitation of God," should have been "Died of two physicians and a surgeon." Heroic remedies would never again be heard of. Rightly regarded, there was no more a "cure" for disease, simply through the instrumentality of drugs or venesection, than there would be hope of educing a new limb, as a lizard spouted a new tail, through lubrication of the stump with a secret ointment or pomatum. He did not wish to undervalue drugs, but simply to contend that if every drug in the pharmacopœia were taken away the medical man would still be powerful for good, falling back, perforce, on man's primitive relations with benignant nature, and sustaining the glorious vigour which was his birthright, through the medium of nature's own simple regimen. How exhilarating it would be to hear the townsfolk shouting less for the ballot, or for female suffrage, according as their fancy led them, and more for laws that, through the agency of the doctor, should give them unbroken health. If he mistook not, nature was nowadays helped to regain her sovereignty not unfrequently through the adoption of formulas of treatment quite independent of the use of what was popularly styled "medicine." The specific action of drugs, moreover, was better understood than formerly, and the tendency now was to simple prescriptions, as opposed to their by-gone composite character.

The lecturer than maintained the right of botany to a place in the medical curriculum, objecting to Professor Huxley's view on this point, and proceeded to advocate the claims of science generally to the attention of the Profession, and to recognition by the State—concluding as follows:—

They could hardly hope to see the day when science would be legitimately endowed, or rather when its ancient and original endowment would be honourably and honestly revived. Science in its early days was amply endowed. That was when science and religion were united in the same persons, the endowments being given to the holders because they were men of science or learning as much as teachers of religion. When science found another home, the endowments remained with religion, though originally intended for both. Had the two things existed primarily in separate establishments, no doubt there would have been separate endowments; and it would mark an era in the history of justice and common sense when science was restored to her ancient footing as to deserts. When that millennium arrived, the medical man's title to a share would be recognized, for medicine was in itself a science, and, though not one of the exact sciences, it partook of the improved complexion of science in general.—To the student this should be specially encouraging. From being the most conservative of sciences medicine, indeed, had become the most liberal. The time was when it consisted in little more than blind reverence for the traditions of the past. Now they had exchanged speculation for observation, rising from facts to principles, instead of looking for facts to substantiate dogmas laid down in the dark. In conclusion, he would strongly recommend the students to qualify themselves by diligent study for the positions which they hoped to fill. He hoped they would sustain the dignity of their profession. Rendering services to mankind was the justifying cause of all dignified position. In whatever else they might imperfectly succeed, that, at least, was their own.

PROGRESS OF PHYSICAL SCIENCE.

At Owen's College, Manchester, Dr. Balfour Stewart, the newly appointed Professor of Natural Philosophy, opened the session with an Inaugural Address, "On the Recent Developments of Physical Science." He contended that the world was undergoing a physical deterioration of a remarkable character. A process of degradation was at work which apparently had no limit, and which would only end when the universe, or at least our part of it, had become entirely unfit as a residence for organised beings. The sun, as many familiar illustrations showed, was the great source of our material well-being. It prepared the food which supplied our frames with energy, as well as with that delicately-constructed tissue which was essential to animated existence. But the sun was

only a great fire, and it was apparently a fire that had long since ceased to be fed. Indeed, the solar orb, with all its wealth of energy, yet resembled a man whose expenditure exceeded his income. There was only one issue, unless we could see an end to the process of waste; but we failed with our present knowledge to see any prospect of such a change. We were thus lead to contemplate the degradation of the universe, or, at least, of our own part of it, ending in a total absence of all useful energy and of all life. These were issues upon which the man of science might speculate with advantage; but it should always be borne in mind that our present intellectual stand-point was very low, and our knowledge of nature's laws very incomplete. Scarcely less important than our increased knowledge of late concerning the laws of nature was the advance we had made in our knowledge of the great bodies of nature—in which branch investigations had been greatly aided during the last ten years by the use of the spectroscope. Descending to our own earth, there was some reason to suppose that we were knit to our luminary, and possibly through him to the other members of our system, by some other bond besides that usually recognised, General Sir E. Sabine appeared to have proved that disturbances of the earth's magnetism took place most frequently in those years in which there were most sun spots. This was confirmed by the experience of the present year, during which we had a great number of sun spots, and frequent and large disturbances of the earth's magnetism—accompanied ten days ago, as usual, by bright appearances of aurora borealis. In connection with the meteorology of our globe, it had not yet been traced whether the earth's climate and atmosphere were influenced in any way by the changes taking place in the atmosphere of the sun; but this connection, important though the question was, had hardly yet been sought for in a proper manner. Recent observations discussed by Mr. Baxendale led us to think there might be some connection between the daily changes in the earth's magnetism and the daily motions of the air. Coupling this with the fact that the frequency of terrestrial magnetic disturbances would appear to be connected with the appearance of sun spots, we were led to contemplate at least the possibility of some connection between meteorology and sun spots. If these remarks were of any value, they tended to indicate the probable union of the various branches of observational inquiry into one great cosmical research, and pointed to the wisdom of a very close union between the workers in the cognate fields of meteorology, terrestial magnetism, and celestial physics. Unfortunately, this prospect was delayed somewhat by our extremely limited knowledge of the various components of the earth's atmosphere—by the backward state of physical meteorology. They were all aware that at the present moment a Royal Commission was inquiring as to the relation between science and the State; and perhaps, therefore, they would permit him the opportunity of stating his views as to the manner in which this very necessary assistance might best be given. He thought that those branches of science which demand for their extension experiments not requiring very great time might be furthered with much advantage in institutions such as Owen's College. He believed it to be advantageous to bring the highest class of physical teaching into contact with research. If Goverment were disposed to grant pecuniary aid to such researches, an extension of the allowance made annually to the Government Grant Committee of the Royal Society would appear to be a very legitimate way of accomplishing this object.

THE ROYAL VETERINARY COLLEGE.

Professor Tuson delivered the Inaugural Address. He remarked that the institution had been established for more than two-thirds of a century, but during the greater portion of that period no proof was required of the possession of a scholastic education by those desirous of becoming its pupils. Five years ago the governors, inspired by the educational spirit of the times, passed a regulation by which it was rendered compulsory for everyone, prior to being admitted on the roll of students, to give evidence of their proficiency in dictation, reading aloud, and the first four rules of arithmetic. For five years this examination had been conducted by the professors, and so satisfied had they been of the good effects resulting from the new regulation, that it had recently been suggested to the governors that it would be desirable to gradually increase the extent and stringency of the matriculation examination, and that the responsibility of conducting it should be transferred from the professors to the members of some independent body. Such suggestions had been adopted, and it was now the pleasure and satisfaction of his colleagues and himself to know that previous to the opening of the present session the matriculation examination had been, and that it henceforth would be, entrusted to the College of Preceptors.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

REPORT AND DISCUSSION ON THE UTILIZATION OF SEWAGE.

A report, which was a very elaborate history of the experiments of the committee, had already been submitted to the mechanical section, where the subject was discussed from an engineering point of view, and it was understood that in section B the question would be treated scientifically.

Professor Corfield then gave a sketch of the contents of a work to be issued by the committee, and which is intended to explain the present position of the sewage question. The subject was treated under the two heads of treatment and utilization, by treatment being meant the removal of all refuse matter from human habitations. In compiling the work he had followed a kind of natural history order, beginning with the simplest methods that had been proposed for the treatment of refuse matter. The first chapter was on the early systems of middens and cesspools. This was followed by a chapter on the sanitary aspects of the question. The third chapter was on improved midden heaps and cesspools, and then the dry earth system was discussed. The information in these chapters was mainly derived from the report of the Government medical officer and the Indian report on the earth closet system. Then there was a chapter on the public health aspect of the sewage question, and a chapter on the different methods of precipitation. He had come to the natural conclusion that it was impossible to precipitate effectually, the only process which seemed to have any *raison d'etre* at all was Blythe's. The work then dealt with the treatment of sewage by filtration and irrigation, and lastly, the question of irrigation was viewed from a sanitary point of view. On the last point it was shown that sewage farms could be made a nuisance, but that they need not be a nuisance, especially if the solid matters were separated and mixed with town ashes or street sweepings. It was shown conclusively that where sewage farming had been carried on worst, viz., at Milan, where the farms were stagnant marshes, intermittent fevers were caused; but it was equally clearly shown that the fevers were caused by the irrigation of land with water containing no sewage whatever. There was nothing to show that the water containing sewage was more favourable to the development of fever than water without it. Where there were not marshes there was no evidence of intermittent fevers. With regard to typhoid fever and cholera the evidence even from the marsh farms was that when cholera and fever had been rampant in Milan, there had not been a single case on the farms. Professor Corfield then read a report on Dr. Russell's analysis of a number of samples of London sewage, the general results of which were to show that the proportion of carbonic acid gas was ten times the amount contained in ordinary air; that there was no sulphuretted hydrogen; and, with regard to ammonia and albuminoid ammonia, four gallons of the air contained only a slight trace of ammonia. The conclusion was that the air was much purer than could have been supposed, taken, as the specimens were, in the month of August. The Professor then described an experiment which the committee had undertaken, with a view to test whether endozoic diseases could be propagated by sewage. The committee purchased three families of guinea-pigs, each of four members. One member of each family was examined, and it was reported that no sign of the disease was to be found. The three surviving members of one family were now being fed with sewage produce only, one with unsewage produce, and one with unsewage produce known to contain larvæ. When the experiment was completed the animals would be killed and examined, and the committee intended to prosecute experiments of this kind on a larger scale.

Mr. GRANTHAM said that several roots and grasses which had been manured in this way were also submitted to Dr. Cook for examination, and he found nothing which was at all injurious.

The PRESIDENT congratulated the section on the attention they had given to this important subject. They had now for the first time a committee formed of engineers and chemists to work out the subject scientifically, and he thought that in the short time they had been at work the results were most interesting, and justified them in looking forward next year to a still further enumeration of most important results.

Dr. PAUL protested against the idea that the report was issued with the authority of the association, or even of the whole of the committee. Three out of the six members of the committee appointed last year had taken no part in its production. For himself, he disclaimed all responsibility, and he believed he represented the feeling of half the committee. He entirely disapproved of the course taven by the committee in the inquiry. It was inconsistent, first, with the engagements and pledges into which they voluntarily entered when they applied to various towns for grants of money for the inquiry, and in the next place it did not promise any kind of authoritative result. (Applause.)

Mr. DAVID FORBES, F.R.S, then read a paper on "The Utilisation of Sewage, with special reference to a phosphate process." The professor, after describing the processes, mechanical and chemical, by which sewage has been dealt with, alluded to irrigation, and said that while fully admitting the advantage of sewage irrigation applied to certain localities, he believed they would agree as to the importance of searching out for some chemical process by which the sewage might be at once deodorised to such an extent that the liquid could be run off into rivers or the sea without danger to health, and thus obviate the necessity of erecting costly works for its utilisation at a distance. In 1845 works were erected in Edinburgh in which the sewage was treated with lime. This had proved a complete failure both in a sanitary and chemical point of view. The next system was the treatment of sewage with lime and chloride of iron. That was an improvement, but it had also failed. The next system was founded on the principle that alum had a very purifying effect upon water from the tendency of alumina and its compounds to combine with organic matter. Then came the A B C process, which was effected by an extraordinary combination of substances, consisting of clay, alum, and blood; but this also the River Pollution Commissioners had declared to have failed in the purification of the water. Mr. Forbes then called attention to what he said was an entirely novel process, brought forward by Dr. Price and himself. It was founded on the fact that certain mineral phosphates, especially those containing alumina, eagerly combine with the organic matter of sewage. A solution of the phosphates and milk of lime was added to the sewage, and the ammonia was precipitated in the shape of a double phosphate. Mr. Forbes illustrated the process with a bottle of Liverpool sewage, and the result was that in a few minutes the precipitate was seen falling to the bottom, leaving the water perfectly clear and free from smell. In another experiment he added ink to the sewage, which gave it a black colour, but the colouring matter was at once removed by the addition of the solution of phosphates and the lime water. In fact, he contended that the sewage water so purified could be drunk without offence, and he caused some amusement by drinking a wine-glass of the water clarified from the London sewage. Before recommending the process he said they must be prepared to answer two questions—first, whether the water was sufficiently pure to be permitted to flow into rivers; and, secondly, whether the valuable constituents of the sewage had been precipitated. He proceeded to show that the answers to both questions were satisfactory, and in conclusion he expressed an opinion that his process would be extremely valuable in such localities as were found unsuitable for sewage irrigation.

The PRESIDENT thought it quite likely that the system would succeed in those cases in which irrigation could not be successfully applied. They required all the help both of engineers and chemists before they could hope for a solution of this most difficult question.

Mr. HOPE trusted the scheme would succeed. The difficulties in the past had arisen from the fact that chemists had too much disregarded the engineers' point of view, and engineers had disregarded the chemists' point of view.

Dr. VOELCKER thought that both chemists and engineers were apt to take no notice of the poor agriculturist who had to use his valuable material. Valuable it was when in its right place, but he was afraid that in many cases sewage was a great nuisance, which ought to be converted by every available means into a harmless substance. The question was, What were those means? His opinion was that the land was the only proper medium which would effect, speaking practically, the complete deodorisation of sewage. But that land ought to be in a condition fit to receive the sewage, one essential condition being that the sewage should not go over the land but through it. It was in the soil itself that the process of purification, oxidation, and the removal of what was really useful in the liquid must take place. Unfortunately, there were few soils in a condition at present to receive sewage without allowing it to flow over the land. Of that nature were badly drained soils, particularly clay soils. Hence there were in many cases great difficulties. If all the land of England were in a high state of cultivation, he was sure we could do with one-third or one-fourth the quantity of land we must now take in most places to effect the complete purification of sewage. In some localities the difficulties of effecting the purification of sewage on account of the impenetrability of the stiff clay soils was very great, so much so, that he believed means would have to be adopted before the sewage was put on the land to remove, at any rate, the suspended matters, which were a great source of inconvenience and caused disagreeable smells. We had not looked sufficiently in the face all the inconvenience which this suspended matter in sewage presented. In the case of light, gravelly soils the inconvenience was not so great, but in dealing with soils the particles of which in wet weather ran together then the removal of the suspended matter was absolutely necessary. Something he was perfectly sure would have to be done in most cases, or else a nuisance would again be created on the land, and we would not gain that practical benefit for which the farmer had been looking for so long. He cautioned corporations in dealing with this question against looking too much for remuneration in dealing with sewage, and thought they should take an interest in the question apart altogether from its pecuniary aspect. As a means of separating the suspended matter from the sewage, he was in favour of artificially prepared filter beds.

Dr. GILBERT pointed out some sources of error in calculating the results of sewage applied to land. It was sometimes forgotten that the sewage had to be applied all the year, when available, as well as when not, and the question of purification must be considered when crops did not grow as well when they did. He agreed with the opinion expressed by Professor Williamson in another section, that no process was yet known by which the offensive matter could be removed from sewage and leave manure which would pay the cost of production. The result of ten years' close consideration of this subject led him more and more to the conclusion that with large populations water was the only mode of cleansing, and if they had water, irrigation was the only mode of utilisation and cleansing.

In the course of the discussion which followed an opinion was expressed that the endozoa egg, even if deposited in the root of a plant, could not be found in the leaves.

Professor HUXLEY remarked that there was necessity for great caution in drawing conclusions upon this subject. It would certainly be an extraordinary circumstance if the egg could creep from roots to foliage, but what had not been taken into account was the extraordinary changes of form which the insects which lived in cattle were capable of undergoing. It was not simply the egg that had to be dealt with, but the egg plus a number of stages and conditions which made it capable of living in different circumstances from the parasitic worm. In illustration of this he mentioned the disease called the "staggers" in sheep. These were caused by the presence of a large endozoon developed in the brain of the sheep, which became a bladder-like substance, and ultimately caused death by apoplexy. The history of that creature was one of the most astonishing in the world. The abominable animal existed in other conditions. If they took the brain of a sheep which had died of this disease and fed a dog with it, it would eat it with great rapidity and delight, not being aware of the percentage he had to pay. (Laughter.) The dog took in the bladder-worm, which in his stomach became metamorphosed—it became a tapeworm, developed rapidly and gave rise to joints containing the ova of the creature, which it never would do in the brain of the sheep, and eventually it was passed out with the refuse of the dog, and scattered upon the pastures on which the sheep were feeding. Some of the insects would be dispersed, but some would remain, and it was

certain that by one or other of these channels the ova got back to the sheep. They then took a different course, and bored through the alimentary canal, were carried to the brain by the circulation of the blood, and there give rise to the staggers. So that it was found the best way of keeping the staggers under was to look very sharp after the dogs.

Alderman RUMNEY, of Manchester, said he thought the committee had shown a bias to the wet system, and had not done justice to the dry system. He thought this unfair to those towns that had subscribed in the expectation that the committee would obtain all the information they could with regard to both systems. No allusion had been made to Hull, where the dry system had most successfully worked, so much so that the death-rate had decreased from thirty-three to twenty-two per thousand.

One or two other speakers also expressed an opinion that the committee had too much confined their investigations to the wet system, and the speakers expressed a wish that more members should be added to the committee.

The PRESIDENT said it appeared to him that while the irrigation question was one of chemistry the dry system was not, or, at any rate, it required less investigation. Whether one or the other came to be generally employed, it was important for chemists to have a clear idea of irrigation. That appeared to him the reason why the committee had given their attention so much to this subject.

This closed the discussion, but a general wish was expressed that it should be continued, and the President remarked that the subject would come up again in the Statistical Section.

There was not time for the reading of any of the other papers set down, and the majority of them were left over until to-day. Mr. E. C. Stanford stated briefly the result of his experiments on the retention of nitrogen in charcoal. Dr. Bischoff exhibited a new filter he has invented for the purification of potable waters, and Mr. James Hargrave explained his mode of separating phosphoric acid from iron furnace cinder.

The section then adjourned.

19TH SEPTEMBER, 1870.

MR. ALFRED HAVILAND read a paper on

A PROPOSED RE-ARRANGEMENT OF THE REGISTRATION DISTRICTS OF ENGLAND AND WALES, FOR THE PURPOSE OF FACILITATING SCIENTIFIC INQUIRY.

The author commenced his discourse by stating that the registration districts of England and Wales were formed for the general purposes of the Poor-law Administration, and therefore it could not be expected that they were planned with any view of assisting science; they had, however, done so when in their present crude and artificial form, and it was generally believed among scientific men that if their boundaries were determined on a natural system, the advantages to meteorology, climatology, and other branches of science would be incalculable, and the expense and confusion of constant alterations avoided. Messrs. Keith Johnston had lately been much engaged by him in the rectification and completion of the registration maps of England and Wales, for the purpose of insuring extreme accuracy in his basis map of the geographical distribution of disease in England and Wales. This had involved him in a considerable extra outlay, but through the recommendation of the Registrar-General, the Treasury, seeing the necessity of the work, had expressed their approval of a grant being paid to Mr. Haviland for the extra expenses incurred. He urged that the artificial system adopted in defining the boundaries of the registration districts had been the cause of all this extra work and expense, and that it had nothing whatever to recommend its continuance; on the contrary, it was the fruitful source of repeated alterations, and would continue to be so whilst it was persevered in. On the other hand, the author showed that were a natural system substituted for the present one, and our country divided into districts regulated by its watershed and river system, we should then have in every district a focus of scientific inquiry, whether it be as to the rainfall, temperature, prevalence or strength of winds, agricultural statistics, the produce of our fields, our mines, or our rivers, or for the purpose of registering the occupations, the diseases or the deaths of the people. Moreover, such a system would form the best basis map for every future census, and being once established upon a well considered and natural plan, would do away with the necessity of those eternal alterations which are now year by year going on, to the utter confusion of the scientific student. In France the watershed system is adopted in defining and naming the departments, it is vastly superior to our own, and although its deficiencies are numerous, yet they will act as beacons to us. The author was well aware that such a revolution could not be accomplished under ten years, therefore he urged the necessity of commencing it at once. Should the natural system be adopted before 1881, it would be ready for the census of that year, by which time the Registrar-General will have completed two more decades of mortuary records under the present system, and, with the one (1851-60) which Mr. Haviland had geographised, will form a most important foundation for all future enquiry. Mr. Haviland proposed that a committee should be formed to take the whole matter into consideration, and report thereon, first to the British Association, and then to Her Majesty's Government.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. VIII.

THE CRAIGENTINNY SEWAGE MEADOWS, NEAR EDINBURGH.

THESE meadows have long been notorious, as the most filthy and offensive plots of cultivated ground in Great Britain. They are also remarkable for their so-called extreme fertility in producing the largest produce of a coarse, rank, and washy grass, which, like brewer's grains, is only fit for the food of milch cows, pent up in the close sheds of a town dairy, where quantity and not quality of milk is the desideratum.

They are situated about two miles to the east of Edinburgh, upon the sandy shore of the Frith of Forth, and they have an area of about 250 acres. The sewage is poured upon them from an open sewer called the "*Foul Burn*," which drains a district in Edinburgh with about 80,000 inhabitants, where water-closets are not in general use. The *Burn* runs eastward and northward from the city, and passes through a small sewage farm of about thirty acres (the Lochend farm), twenty of which are in permanent grass, and the rest in Italian rye grass. The tenant of this farm takes the sewage when he likes, and he also takes as much of it as he likes, and the rest of it runs eastward in the open *Burn* to the Craigentinny meadows, and thence, if not wanted, to the sea. As it passes through the meadows it is distributed upon them in the most profuse manner, rendering the ground a swampy sewage morass; in fact, the effluent water which runs off by many channels, and trickles away to the sea-shore, is as foul as it can well be. The smell from the open *Burn* and the swampy meadow is so powerful that it is offensive to the whole neighbourhood. The soldiers at the neighbouring cavalry barracks at Piershill complain of it as a serious nuisance, and say that at times is quite sickening. Dr. Ligertwood, the surgeon of the 8th Hussars, attributes the absence of disease among the soldiers while stationed there, in 1868, to the fact that the site of the barracks is open, and well exposed to the sea breeze, which counteracts any evil influence from proximity to such fields, and thus, he says, they maintained their health "in spite" of the nuisance.

But although the quantity of sewage thus put upon the land is enormous, yet a large amount of it is still per-

mitted to flow into the sea unutilized, notwithstanding that there is plenty of land at a slightly higher level upon which it might be distributed. Looking at the fact, as set forth in the constantly reiterated statements of those who speak of the large profits of the Craigentinny farm, that from £24 to £36 an acre are realized from the use of sewage upon a barren waste, it is remarkable, at first sight, that any of the sewage should be allowed to run to waste while there is an acre of land to utilize it. The paradox, however, is easily explained, for as there is but a limited demand for Italian rye grass, which is the only crop that can be profitably cultivated, it would be folly to produce more of it than can be sold. At the time of our visit to the meadows, in 1866, there were acres upon acres of the grass rotting upon the ground, because the cattle plague had killed the cows, and the demand for such fodder had ceased. The sewage, therefore, was running away to sea by its natural channel, and the ground was almost entirely abandoned. We had great difficulty in finding the man who had charge of it, and he told us that they would gladly give the grass to anybody who would cut it and carry it away, and that during the year they had not realized above £7 an acre for even the best plots of the ground.

The soil of the meadows at the lower part is almost entirely sand, reclaimed from the sea-shore, but at higher levels it is good arable land. A little of the higher land (about eight acres) is irrigated by means of a steam pump, but as we have already said, there is no inclination to utilize any more of this land, although it is not more than ten or fifteen feet above the level of the burn, because of the limited demand for the succulent produce; the sewage, therefore, is allowed to run to waste, and the land is cultivated with ordinary manures.

It will be evident from this that the Craigentinny meadows are not examples of what *should* be done with sewage, but rather of what *can* be done with it, when all sanitary considerations are out of the question, and when, at the will of the tenant, the sewage can be utilized or not. But how would it be if there was no neighbouring sea-shore for the reception of the sewage, and the purification of it by proper irrigation were an imperative necessity? The answer is self-evident, for the rank grass would have to be sold in an overstocked market for what it would fetch.

Summary of Pharmacy.

Specially edited for the Medical Press and Circular.

By Chas. R. C. TICHBORNE, F.C.S.,

Chemist to the Apothecaries' Hall of Ireland, Corresponding Member of the Philadelphia College of Pharmacy, &c.

OINTMENT OF NITRATE OF MERCURY.

Mr. R. Rottur in the *Chicago Pharmacist* gives the following formula:—

Take of Mercury, 1½ oz.;
Nitric acid (sp. grav. 1·420), 3½ oz.;
Lard, 16½ oz.

The directions are, that the mercury should be dissolved in 900 grains of the nitric acid with the aid of heat, and that the solution should be kept gently warm so that crystallization should not take place. The lard is melted in a suitable vessel, and when moderately warm the remainder of the nitric acid is added without stirring as long as moderate effervescence continues, if this effervescence becomes too violent it is removed from the fire, and replaced when the action begins to slacken; it is again removed from the fire and when it begins to stiffen the mercurial solution is added and mixed thoroughly. The object of the writer is to produce uniformity of result by conducting the two stages of the operation separately, he therefore uses part of his acid to make the mercuric nitrate and oxidizes the fatty acid by the remainder of the nitric acid in a separate operation. The process is certainly more "chemical" in its character, and is likely to lead to better results in the hands of inexperienced operators than the pharmacopœiacal one. We have tried the process and find that it gives fair results. It should be borne in mind that the American ounce is an ounce troy.

COLLYRIUM OF ATROPIA.

M. Sichel gives the following in the *Journal de Pharmacie* for August:—

Neutral sulphate of atropia	·01	of a gramme	1	part.
Distilled water	10·	,,	1000	,,
Glycerine	5·	,,	500	,,

This preparation may be used for dropping into the eye, or smearing round it. For the latter purpose it possesses no advantage over that proposed by the Editor of this "Summary" many years since, the following is his formula: one decigramme (1·543 grains) of atropia are dissolved in a few drops of spirit and added to 20 grammes (268·63 grains) of distilled glycerine without stirring, and the mixture is then subjected to a gentle heat for half-an-hour to evaporate the alcohol. This will contain about two grains to the ounce of the atropia. It may be diluted for dropping into the eye with three parts of water. It should be borne in mind that the glycerine used in connection with eye lotions, should not only be distilled and therefore give no precipitate with nitrate of silver, but it should be perfectly sweet to the nose. Distilled glycerine may, and frequently does, contain volatile products of an irritating nature.

GLYCERINE AND TANNIN.

The same journal gives a formula for the above preparation, which is used extensively in Paris as a remedy for sore nipples. It differs from the *glycerium acidi tannii* of the Pharmacopœia in containing 50 per cent. of tannic acid instead of 20 per cent.

Take of tannic acid, 5 grammes;
Pure glycerine, 5 grammes.
Dissolve with the aid of heat.

BLISTERING TISSUE.

MM. Delpech and Guichard publish the following formula:

Take of Gelatine, 30 grs.;
Water, 150 grs.;
Alcohol, 150 grs.;
Cantharidate of potash, 6 grs.;
Glycerine, 9s.

Thin gutta-percha is covered with this material so that about four millimetre square should receive 1-8 to 1-7 of cantharidate of potash.

The advantage claimed is the non-volatility of cantharidate of potash compared with cantharidine.

Cantharidine, as mentioned in our "Summary of Science" some time ago seems to act as a fatty acid, and forms well defined and crystallizable salts, which possess the vesicating property of cantharidine itself.

As regards the merits of MM. Delpech and Guichard's preparation we cannot say anything, not having had an opportunity of trying it, but one important objection to it is, the enormous expense of cantharidine, and until this is reduced we do not think that any preparation in which this substance is used can come into use.

There is another point which requires correction; cantharidine is not practically volatile at ordinary temperatures.

The Editor determined this point by placing one grain of cantharidine upon a watch-glass and putting this in a large glass case, where light and air, but no dust had access to it. At the expiration of six years it showed no signs of loss, nor were even the edges of the crystals rounded as they would be if volatilization had taken place.

LIQUOR CARBONIS DETERGENS.

The following formula appeared in an obscure corner of one of the numbers of the *Pharmaceutical Journal*. We are assured that it is the original formula for the above preparation which has been used to some extent in the Profession:—

Take of Bruised bark of Quillaya saponaria, 4 lbs.;
Sp. Wine (methylated 65 per cent.), 5 gals.

Heat to ebullition and macerate for some days in a sand or water-bath. This tincture is then used for the preparation of saponified coal-tar in the following manner :—

Take of Coal Tar ℥xxxij.;
" Tinct. of Saponaria, ℥ixxvj.

Digest eight days in a water or sand-bath at a moderate temperature. occasionally stirring the mixture and then filtering for use.

The Quilla saponaria is now a well-known bark which produces a saponaceous decoction of a detergent nature, an account of this bark which is indigenous to Mexico will be found in the *Pharmaceutical Journal* some years back.

It belongs to the *Rosaceæ*, and is a hardy evergreen shrub. The chief chemical characteristic is the large amount of saponine (C_{12} H_{20} O_7), a white non crystallizable powder, also found in senega root, saponariæ and many other well known plants. It produces in water a frothy solution, and the powder excites violent sneezing. It forms a precipitate with neutral acetate of lead, it also contains crystals of oxalate and tartrate of calcium, which are so interwoven amongst the structure of the bark that a thin section of that substance forms one of the most beautiful microscopic sections of its class known.

MISCELLANEOUS.

Coating pills.—Mr. Ebert, in the *Chicago Pharmacist* recommends the use of an etherial solution of resin for coating pills.

Substitute for lint.—Mr. Pownall says that finely picked oakum has been used successfully as a substitute for lint.

Cantharides.—The young insect is said to contain no cantharidine, and to be destitute of blistering properties.

Registered for Transmission Abroad.

THE
MEDICAL PRESS AND CIRCULAR

Is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Stamped, 6d.

Post Free to Annual Subscribers £1 2 6

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 12, 1870.

REDUCTION IN THE SUBSCRIPTION OF OUR JOURNAL.

THE NEW POSTAL REGULATIONS.

The course which the Medical Press and Circular shall pursue in reference to the new postal arrangements has been a subject of anxious consideration with us. On the one hand we have felt bound to give our subscribers the entire benefit of the reduction in our expenditure, and the question has been only in what way that could best be done. On the other hand, the postal authorities interposed so many disabilities and obstructions to the carrying out of our intention that we have found it difficult to do so. In fact, the Postal Act appears to have been carefully framed to prevent the introduction of improvements in such periodicals as the Medical Press and Circular, and to confine the benefits of the halfpenny postage to ordinary newspapers, and we have been obliged, therefore, to submit to the penalty imposed by the Post Office.

It is right that our subscribers should be aware of the exact circumstances. Our expenditure is reduced by one farthing per copy, or 1s. 1d. for each annual subscriber. We have felt that the remission of the sum would be insignificant, and would make our subscription accounts complicated in the working, and we have resolved, therefore, to reduce the rate for advanced payment with the new year to £1, and thus add one-half more to the *bonus* which the postal authorities offer our readers.

We have said that the postal authorities have desired to prevent journals like ours from availing themselves of the new arrangements, and they have attempted to do so by enacting that no periodical shall pass for the halfpenny which is stitched. While we feel that it is a narrow-minded and illiberal policy in a professedly Liberal Government to throw difficulties in the way of publishers making their periodicals as perfect as possible, we are compelled to obey, and in future our Journal will be delivered carefully cut, but not stitched. It likewise deprives us of the privilege of re-transmission.

The Medical Press and Circular will in future be the cheapest medical Journal in the United Kingdom, and we pledge ourselves, that if our efforts can avail, its value as a professional and scientific record shall increase as its price decreases. As the success of any publication depends primarily upon the efforts of its subscribers to obtain additional supporters amongst friends at home or at a distance, we appeal to those who know the independence and impartiality of the conductors of this Journal to further extend its influence and promote the best interests of our common profession.

OPENING OF THE MEDICAL SESSION, 1870-71.

After our usual custom, we this week present our readers with abstracts of the Opening Addresses, or Introductory Lectures, as they are more properly called, delivered on the 1st and 3rd of the month at the various Metropolitan and Provincial Schools of Medicine.

The dreadful war, now so bitterly waged on the Continent, was made by several of the lecturers a text, from which good and wholesome lessons were drawn; at University College, indeed the chief part of Mr. Berkeley Hill's most interesting lecture related to military surgery and hygiene, and came well from one who had so recently returned from a visit to the hospitals of Saarbrück and Sedan. We may congratulate Mr. Hill on his perfect coolness, under the occasional uproarious outburst of applause from the upper regions of the theatre, which might indeed have been overwhelming, we will not say to a modest man, but certainly to a nervous one.

Westminster Hospital was happy in selecting Dr. Sturges as its introductory orator, and it was most pleasing to observe there the marked attention paid, not only by the students and visitors, but also by the staff of the hospital, who mustered in very full attendance. Dr.

Sturges set himself, with good effect, to teach men how to learn the profession of medicine, and how to practice it for a livelihood in a way that would be straightforward, honest, and elevating both to themselves and their patients. The doctor was to be, in the true sense of the word, a healer, and not a dealer in drugs professing to have a physic for every mortal ache and pain, and likely to succeed only as he managed to hitch the lever on which he sought to raise himself to fame securely on the fulcrum of human credulity. The words of a good physician were aptly quoted by Dr. Sturges as follows: "When I began my career I had for every disease twenty medicines, and now, at the close of my career, I may say there are twenty diseases for which I have not one remedy." This may seem to the student a discouraging piece of experience, but we believe the words were those of Radcliffe, the greatest practical physician that the two past centuries ever saw. A man who observed closely, quickly guaged and made available the merits of the inventions of his day, was faithful and honest even to madness, and left, as the results of wealth amassed in high and honourable work, the infirmary and library at Oxford, both of which bear his name. We would gladly dwell at length on many other of the excellent lectures with which this session has commenced; a most commendable feature, in our opinion is, that the lecturers devoted themselves generally to giving good and plain advice to the students as to how they were to learn the profession of physic and fit themselves for its practice. The criticisms of some of the teachers on the examining boards could not be said to be out of place, and we recommend the Senate of the University of London to glance over Dr. Cayley's address at Middlesex Hospital. We entirely agree with Dr. Cayley, and do not think the sole object of student life is to pass examinations. Looking back to men who have carried off high university honours, it is painful to see how many of them have been utter failures as practical physicians and surgeons. A story is told of an M.B. in high honours entering upon office as house physician, and prescribing a very scientific and complex pill, which, when made, had to be placed in a drawer, as no pill box could be found big enough to contain it.

The address of Dr. Sutton will be found given *in extenso* in our journal, and we trust will be read from first to last. We would earnestly say to students mind what Dr. Sutton says, and be known as painstaking physicians and surgeons, don't seek to cultivate a habit of "seeing at a glance" too early. To some this faculty comes as they gain experience, and a valuable faculty it is when it thus grows by degrees, and almost unconsciously, in one who has begun as a plodding painstaking man, but for a man to aim at such a method as likely to give his patients confidence, is a delusion and a snare, likely to lead to ridiculous, if not serious, blunders and irreparable loss of confidence on the part of the patient.

We know that it is one thing to preach and another to practice, and that it is an easy thing to give good advice or even to manufacture eloquent well-turned phrases, but we feel sure we may affirm of one and all of the lecturers who have this year opened our medical schools, that the students will find that as they say so they do. As the session progresses the new student will become more familiar with his lecturers, he will see them during their work in the theatre, the wards, or the out-patient room of the hospital; he will there see with what laborious and patient toil the hospital physician or surgeon gathers that learning and experience which enables him at the Opening of the Session to address to the students words of valuable counsel and advice, and to speak as one with the authority of experience.

In conclusion, we would say to all students, set yourselves to the one object of thoroughly learning your profession in all its branches, so that when a few years hence you may be engaged in practice either for yourselves, or as assistants, you may not have on meeting with a rather unusual case of surgery or midwifery, at once to run for the aid of those better taught than yourselves, and see them do with ease that which you ought to have been able to do with equal facility had you but made good use of your opportunities while at the hospital.

The chances you have of learning while at the hospital will not come again; in the case just propounded you learn doubtless, but it is probably at a considerable loss of standing and repute, and it will avail you little to display gold medals and certificates of honour before your patients if they find that when you meet with a case of broken bone, or encounter a breech presentation, or a head descending a little out of accordance with the teaching of your book, you are at once obliged to send for the assistance of another practitioner, who may by his doing, if courtesy restrains his tongue, convince people that the case was most simple and perfectly easy of management.

If, in the course of your learning, medals and prizes befall you, well and good, but don't go away from the beaten path to gather such flowers as these; remember, you who are gifted with high and brilliant talent, that the lame man who keeps on in the road will outstrip him, who, though fleet of foot, strays from the path after dazzling trifles.

CROYDON SEWAGE AND THE TOWN WELL.

Our worthy contemporary, *The Croydon Chronicle*, is very wrath with us for saying, in our Special Report of the Croydon Sewage Farm which was published last week, that "the whole of the subsoil water of the locality (of Beddington) is so tainted as to be unfit for drinking purposes, and that every well is polluted; in fact, according to the analytical enquiries of Dr. Frankland, as stated by Dr. Carpenter, the chalk well in Croydon, from which the water supply for the town is obtained, is charged to a large extent with nitrates and the other oxydised products of sewage." This statement, according to our contemporary, is a pure invention, for he says, "we are quite convinced that Dr. Carpenter never stated anything of the kind, even in the loftiest flights of his conjectural imaginings." That there may have been very lofty flights in Dr. Carpenter's conjectural imaginings, even with so prosaic a subject as Croydon sewage, is most probable, and we are ready to admit as much if it would in any degree calm the wrath of our contemporary, who is the Doctor's near neighbour, and who is, no doubt, a reliable authority in this matter. But, for all this, we cannot go so far as to allow that our statement is a pure invention, and "that Dr. Carpenter never stated anything of the kind;" for if our contemporary will turn to a note on page 16 of a little pamphlet—which was published at the close of last year by Mr. Warren, of the High street, Croydon—entitled "Some Points in the Physiological and Medical Aspects of Sewage Irrigation, a paper read at the Social Science Congress at Bristol, Oct. 2, 1869; to which is also appended a paper on the Influence of Sewer Gas on the Public Health. By

Alfred Carpenter, M.D.; price one shilling," he will there find that Dr. Carpenter makes the following statement:—"This subject (the presence of nitrates, &c., in water) was discussed at a meeting of the Association of Medical Officers of Health in London some time since, and I asked Dr. Frankland to explain this anomaly (the existence, we presume, of nitrates in the Croydon well). *He did so by stating that he believed that the Croydon well was contaminated with sewage elements by percolation from the irrigated fields at Beddington.*" The italics are ours, and they show the ground on which we rested our statement, "that according to the analytical enquiries of Dr. Frankland, as stated by Dr. Carpenter, the chalk well in Croydon, from which the water supply for the town is obtained, is charged to a large extent with nitrates and the other oxydised products of sewage." We know, of course, that Dr. Carpenter will not admit this to be the case, for, on the one hand, he declares the water to be magnificent, and, on the other, he proclaims the total absence of danger from sewage irrigation. As to the other wells of the locality, and the general condition of the subsoil water of the sewage farm, we beg to assure our esteemed contemporary that the charges we have brought against their purity are derived from our own personal knowledge of them, and from many analytical investigations. Lastly, we beg to say that if our contemporary should feel inclined to continue this discussion, we should, in common with others who take a large interest in the sewage question, be much obliged if he would inform us of the exact condition of the scheme for forming a company to rent and manage the sewage farms of Croydon, and how many of the townspeople, who have heard, and perhaps seen, so much of the valuable results of sewage farming, have taken shares in the project; for, after all, as, no doubt, he will admit, the most practical and reliable test of the value of sewage is the money confidence reposed in it by those who have really had experience of its profitable results,—who have seen, for example, that at all times, and in all seasons, the most magnificent crops of milk-producing and flesh-forming succulent grass are obtained, and that in such a dry season as the present the experimental crop of mangold "is estimated at forty tons an acre."

THE MILK OF DISEASED COWS.

In our impression of the 21st ultimo we referred to the subject of the influence which the milk of diseased cows was likely to exercise upon the health of those who consumed it. Since we wrote, the Annual Report (for 1869) of Mr. Simon, Medical Officer of the Privy Council, has been published; and we find in it a report from Dr. Thorne "On the effects produced on the human subject by consumption of milk from cows having foot-and-mouth disease." Dr. Thorne's inquiries were conducted in several small towns in Sussex, Norfolk, and Hertford, where large numbers of dairy cows affected with the disease were located. The investigations were carried out with great care, but the results were not so satisfactory, either negatively, or affirmatively, as could have been desired. However Dr. Thorne concludes from them:—

"1st. That a disease appears sometimes to have been produced in the human subject when the milk of cows suffering from the foot-and-mouth disease has been freely used without being boiled, there is no evidence to show whether this affection is of a specific nature or not; but it seems to consist in a derangement of the alimentary canal, accompanied by febrile disturbance, the presence of vesicles on the mucous membrane of the mouth and tongue, which having ruptured leave superficial ulcerations, and, at times, a perpetic eruption about the exterior of the lips.

"2nd. That in a very large number of cases the milk of cows, undoubtedly affected, has been used without producing any noticeable morbid effects. The absence of this result may, though only to an inconsiderable extent, have been due to the smallness of consumption, and the boiling of the milk."

Commenting upon Dr. Thorne's report, Mr. Simon says, "that whilst admitting the poisonous nature of milk derived from cows affected with pleuro-pneumonia, there may be circumstances affecting it before its actual consumption, which might modify or destroy its noxious properties, and, on the whole, he concludes that he is clearly of opinion that such milk should not be unrestrictedly sold for human consumption."

Dr. Thorne states that this kind of milk was found to produce fatal effect when drank by young pigs. More than a year ago a Government Veterinary Inspector made a similar observation.

We learn from Dr. Cameron, Analyst to the City of Dublin, and under whose direction the supervision of the sale of all kinds of food in that City is conducted, that there was recently an outbreak of foot-and-mouth disease in Dublin. The malady appears to have been extremely weak, whole herds becoming ill and recovering therefrom in less than a week. The deaths were very few, though there were thousands of cases. The milk was repeatedly examined, but, except in a few hard cases, it did not present an abnormal appearance.

Dr. Cameron made minute inquiries relative to the effect which the milk of the affected animals produced upon those who consumed it, but the results of his inquiries were generally of a very negative character. He gave some milk obtained from a very sick cow to a cat, which immediately after became ill with diarrhœa, and affected with extensive superficial ulcers on the tongue and inside part of the lips. The only decided case amongst man, which came under Dr. Cameron's notice was that of a whole family of children who simultaneously became affected with severe vesicular eruptions on the tongue, lips (inside), and palate. It was found that the cows which supplied the milk (which formed in an uncooked state a large part of their food) were severely affected with foot-and-mouth disease. These children suffered for some days from pyrexia and had diarrhœa, which, Dr. Cameron was forced to conclude, were produced by the use of the milk of the diseased cows.

In Dublin, every effort was made to prevent the sale of the milk of cattle suffering from foot-and-mouth disease; and should the malady re-appear, we believe that the most stringent measures will be adopted to prevent the consumption of the milk of any cows that may become affected—however slightly—with the disease.

SCOTLAND.

Several of the female medical students have availed themselves of the permission granted to them by the lecturers in Surgeon's Hall, and are engaged in dissecting in Dr. Handyside's rooms.

Dr. Allman's resignation has been accepted by the Edinburgh University Court.

Notes on Current Topics.

About the War and Wounded

Our readers will remember the Birmingham Fund, raised by our indefatigable and worthy *confrère*, Mr. Sampson Gamgee. Here is some account of it by Mr. Gamgee:—

The large stock of clothing, wrappers, blankets, bandages, lint, and other materials contributed have been forwarded in assorted parcels never less than twice, often four times, weekly, so that contributors may comfort themselves

in the thought that their help was made available, as rapidly as possible, for the beneficent purpose to which it was destined.

It has not been such an easy matter to forward the surgical instruments, for the simple reason that the makers held but a very small stock, altogether unequal to the sudden and extensive demand; and that the trade being a comparatively small one, the means of production did not admit of rapid expansion. At one moment, the stock of suitable surgical needles in Redditch was quite exhausted, and a person specially commissioned to buy artery forceps in Sheffield did not succeed in obtaining a single good pair, after two days' persevering search. There would have been no difficulty in spending one, two, or three thousand pounds in an indiscriminate collection of surgical appliances, but the difficulty was to select just those instruments which were most needed on the field, to arrest bleeding, and by stemming the out-flow of life's stream, render possible the employment of soothing agents, food, and other comforts of slower operation. Acting on this principle, we have sent out 588 tourniquets to strap round limbs in which the main vessels have been wounded; of artery forceps 307 pairs had been despatched, with 285 little bull-dog forceps to hold on faithfully to those bleeding points in the absence of trained assistants. Our numerous parcels have collectively inclosed 282 dozen assorted surgical needles, 231 reels of suture silk, and 292 reels of metallic suture; 40 bullet extractors, 191 pairs of scissors, 35 amputating cases, and 8 trephining cases, 2,000 yards of adhesive plaister, 360 pairs of blankets, 600 perfectly cleansed sponges, 19,200 doses (two grains each) of quinine, 14,000 doses of morphia (each ¼ grain), chloroform enough for 7,640 operations, on an average of half-an-ounce for each; 2,000 quarts of assorted antiseptics and styptics for checking hæmorrhage and cleansing wounds; 150 water pillows, 2,000 yards of fine gutta percha, 400 yards of waterproof sheeting, 600 bottles of Preston salts, 1,538 yards of Christian's elastic bandages, and nearly 10,000 flannel and calico bandages, rolled by the patients in the General and Queen's Hospitals, under the valued superintendence of the resident officers of these institutions. The whole stock has been so subdivided and arranged as to be easily distributed on the spot; and the packing material has been chosen so as not to be wasted, but directly useful to the surgeons and nurses in their work. The bottles of disinfectants are packed in picked oakum; the chloroform, quinine, and cases of morphia in fine cotton wool; every package being labelled in English, French, and German, on the decimal system. The contributors have been informed, through Mr. Berkley Hill's published letter, that the help sent to Sedan proved most useful. Mr. Priestley Smith reports from Bingen, that the instruments I confided to him were just what was wanted. The Berlin Committee has also approved the Birmingham selection; and I know that valuable cases have for the last five weeks been forwarded by my direction, through various channels, into France, though as yet no news has been received of their delivery; but as they all bear the red cross, and a printed inscription stating object and contents, it is resonable to hope that the poor fellows for whom they are intended will derive the benefit.

***

Amongst the victims of the war, we regret to announce the decease of Dr. Rigaud, resulting from over-fatigue in attending on the wounded. M. Rigaud was well-known in the south of France, and his untimely death will be deplored by all who knew him. He went, on the outbreak of the war, to serve his wounded countrymen, and laboured among them with such devotion as to sacrifice his own life. He was as great a hero as any of the combatants.

***

We had the pleasure of an interview with Mr. Monod, whose ambulance left London for France last week. He had been in service with the Red Cross all through the war, and freely gave us such information as we wished. He is a son of Adolphe Monod, the great preacher, whose name will be dear to many of our readers, is himself an *avocat*, but is now heart and soul in the work of human kindness he has undertaken. That his work is appreciated we may see by our National Society giving him £600 as a subscription. The French Committee will receive subscription destined for his ambulance.

***

Dr. Thomas Guy, Deputy Inspector-General of Hospitals, has translated the pamphlet of Professor Esmarch, of Kiel, "On Bandaging on the Battle-field." Esmarch recommends that every soldier taking part in war should be provided with a new form of bandage, which he could use himself, if wounded, as the first dressing on the battle-field. After great battles thousands of wounded often lie for days without help, and their wounds are exposed to dust, damp, dirt, insects, the sun's glare, or, it may be, to prolonged hæmorrhage, from the shaking to which they are subjected in removal, or the unskilful use of bandages. Professor Esmarch recommends the use of a triangular cloth of linen or cotton, available for application to wounds, however serious, in every part of the body. It is in the form of an isosceles triangle, the longer side, the base, being 4 feet, and the others about 30 to 36 inches. The great and obvious merit of this bandage is its shape. It is surprising in how many forms a soldier, without any previous training, could make a convenient wrapper for wounds with a triangular piece of cloth, whereas experience has shown that only long practice gives the dexterity necessary to apply a long roll to a wound. There is much to be said in favour of Esmarch's plan.

***

Strasbourg has been the scene of many a noble deed, and we rejoice to know that her renowned Faculty of Medicine has been equal to the occasion. The exertions of both professors and students have been worthy of the brave defence, and to those exertions was, no doubt, due the absence of many additional miseries. The awful trial has been passed through with much less sickness than might have been anticipated. Sick and wounded appear to have been thoroughly attended to and well cared-for. We remember, naturally, that the Strasbourg Faculty was one of the most renowned in Europe. Alas! that it should have been tried to such an extent. All honour to it that when tried so severely it was not found wanting.

***

It is said that at Sedan 500 surgeons fought in the ranks, and left 200 of their number dead on the field. Sublime as was their courage, it availed nothing. Would not their skill have been more precious to their countrymen than the little service they could render in the ranks?

***

A *confrère* who reached London at the end of last week, tells us that the ambulances near Sedan were centres of pyæmia, and that this disease had also largely prevailed outside Metz. Of the inside he had been able to learn nothing. He also confirms other observers respecting fever and dysentery. It seems quite possible, after all, that disease may do more than the sword this month and next.

***

We hear glorious news of our *confrère*, Dr. McCor-

mack, who seems to be acquiring extensive experience in military surgery, and whose hospital is reported to be in excellent condition. We expected as much, and are very glad that British surgery is so well represented.

***

The National Society proposes to place a sum of £20,000 at the service of the leaders of each of the hostile armies, of course to be exclusively used for the sick and wounded. Is not this subsidising governments, and helping them to make war? Nothing but the urgent needs of the sufferers could justify it.

***

We learn from correspondents that, besides the diseases already named, "sporadic" cholera has occurred among the German troops. Who can say they are not in danger of a fearful epidemic of this dreaded scourge?

***

Professor Longmore will not be able to accompany the English ambulance. His place will be taken by Dr. Guy, Deputy Inspector-General of Hospitals, aided by twelve surgeons and more than a hundred other persons.

***

A gentleman who has just arrived, assures us that our predictions of disease have been fully verified, that fever and dysentery are rife in the invading army, and that much suffering is still to be expected. He thinks that, unless the campaign can be speedily closed, the mortality will be fearful, and that the Germans may have great cause to regret that their leaders have not secured the fruits of their early triumphs.

The Fall of the Leaf.

THERE is great truth in the observation of many invalids who pull through the summer, dying, unless great precaution be adopted during the sober, ashen, grey weather of October. This withering month is peculiarly trying to phthisical patients scattered throughout the country. All who can afford it, of course, will prepare for wintering in some salubrious climate, either in the south of England or abroad. Each place has its advocate and peculiar advantages. To the great majority whose circumstances and position in life will not permit of change it is that we specially address ourselves. We most strongly urge upon all suffering from chest affections, or who are prone to returns of thoracic complications at this season to prepare either to resist or subdue the attacks. Chest preservers made from hare-skin and lined with chamois will be found efficacious, and a simply-made cotton-wool respirator equally beneficial to be worn, particularly by those whose duties force them out in the early morning or late evening air of October. Some months ago we gave particulars of a very simple and cheap form of respirator devised by Dr. Waring-Curran, which consists of two concavo-convex pieces of porous zinc plate; between the two portions a layer of cotton-wool may be placed, and all kept in apposition by a couple of side springs. A ring at either corner permits the fastening of a silken ribbon for going round the neck. The entire cost of such a respirator is calculated at only a few pence, and Professor Tyndall tells us that in using the cotton-wool the atmosphere of the highest mountain may be breathed in the sick-room of the invalid, so far as purity goes. Dr. Mapother, of Dublin, has devised a somewhat similar kind of respirator to that previously invented and made by Dr. Curran, but it is more complicated and expensive. The great object is having the air coming through the cotton-wool for breathing purposes. And as prevention is better than cure, we particularly recommend during the present and approaching season not only the wearing of respirators, but of chest-preservers also.

Hiccup.

SOME time ago, under the title of "Sneezing," we published a very simple method of controlling it, by pressure upon the upper lip. We are glad to learn from so many different sources the success attendant upon our annotation. A correspondent directs our attention to the subject of hiccup—a most distressing and obstinate complaint to those in whom it occurs. We do not refer, of course, to the hiccup attendant upon great prostration of the system, and met in connection with *delirium*, or convulsions, or to hiccup the effect of debauchery, but to those instances, very frequent indeed, of a simple spasmodic condition of stomach and œsophagus which assails the individual without any other symptom of disease, and in the treatment of which anti-spasmodics prove inert. Our correspondent tells us that for a long term of years he has been invariably successful in affording relief to his patients by directing them to hold their arms straight above the head, and to keep inspiring as long as is feasible, so as to retain the air in the lungs for as long a period as possible. He considers the oxygen of the air acts as a stimulus in provoking the paroxysms, and that the carbonic acid in the unexpired air acts as a sedative in warding off the hiccup.

The Vaccination Grievance.—Apathy of the Privy Council.

OWING to several communications received by us by way of reply to certain remarks of ours upon the apathy of the Privy Council in enforcing Boards of Guardians to comply with the last Vaccination Act, we were assured that in some instances they had actually done so. However, we observe this week that Nottingham is behind. We cannot do better than reproduce the letter of the public vaccinators for the two districts of the city, which tells its own tale:—

To the Nottingham Board of Guardians.

Mr. Chairman and Gentlemen,—We feel it our duty to call your attention to a matter of vital importance to the sanitary condition of the town. We allude to the fact that a large number of the children in this town—especially among the working classes—are entirely unprotected from small-pox. We do not wish to trouble you with statistics in favour of the immense benefits to be derived from vaccination—all intelligent men of the present day are convinced of its absolute necessity. Hitherto it has been most unsatisfactory to find that the intentions of the Legislature have been very imperfectly fulfilled, and the measures taken to prevent the ravages of small-pox insufficient and delusive. It is to be hoped that this slur on our national character will no longer be allowed to exist. Of course, by an appeal to the Privy Council, the very necessary provisions of the Act of 1867 could be enforced, but before taking so decided a step, we thought it our duty to lay the matter before your Board.

The fact that the fatal ravages of small-pox have been devastating Paris is sufficient to justify us feeling anxious about our own immediate neighbourhood.

The large number of French refugees now in England is an additional element of danger. As no eruptive fever is more contagious than small-pox, the mortality among the unpro-

tected infant population of Nottingham would be fearful, and the greatest blame would be attached to those who, having the advantage of education, in addition to their responsible position of Guardians of the Poor, neglect to see that the Act relating to vaccination is enforced. Taking as your motto, "*Salus populi suprema lex*," we appeal to you, gentlemen, as Guardians of the Poor, to protect the unfortunate offspring of ignorant and prejudiced parents, who, instead of showing any gratitude for the immunity now enjoyed, industriously endeavour to restore to us this loathsome disease with all its original force.

A public inspector has recently been appointed, but persuasion only has been tried.

It is now time that he should be called upon to discharge those duties for which he was appointed, and for which he receives a salary derived from the pockets of the ratepayers.

We are of opinion that if an example were made of one or two of the worst offenders, the remainder would speedily avail themselves of the opportunities they have of protecting their children, and so ward off the impending danger.

We have the honour to be, Gentlemen, your obedient servants,

W. Frederick Lill, M.R.C.S. Eng.,
C. J. O. Smith, M.R.C.S. Eng.,
Public Vaccinators for the two districts of the town of Nottingham.

Since Boards of Guardians won't perform the rules laid down for their guidance by the Act of Parliament, and since the Privy Council remain in a state of lethargy, we must only have the question ventilated next session in the House of Commons, when, perhaps, some hidden light may be thrown on the topic.

The Late Dr. Matthiesson.

"Suicide while in a state of temporary insanity" was the verdict of the coroner's jury last Friday evening on the enquiry into the death of the Professor of Chemistry at St. Bartholomew's Hospital. Could there be a sadder opening of the Session at the great hospital of London? Dr. Matthiesson was only thirty-nine years of age, and had attained a splendid position. Only last year the Royal Society awarded to him its Royal medal for his researches in chemistry, and he seems to be greatly beloved by those who knew him. Our readers will probably have noted the details in the daily papers. A false charge had been made against him, he wrote in a letter he left in his private drawer, and "although innocent, yet it blights all my future prospects, and therefore I have resolved to resign all." Then he shut himself in his room, was heard to walk about some time as if in an excited state, and then—was found dead some hours after, sitting as if asleep in his chair, but poisoned by prussic acid. Thus is lost to us in his prime a hard worker in science—a professor in one of our great metropolitan medical schools—who had given an earnest of future fame such as few at his age have done. 'Tis very sad.

Suburban London.

No one can traverse the suburbs of the great metropolis without being struck by the rapid extension of its limits in every direction; and if he has the time to examine further, he will be horrified by the neglect of the commonest principles of sanitary science, and the gross carelessness with regard to the health of the inhabitants of the new buildings. Nature has done much to make London the healthiest city in the world, *man* does his utmost to render it pestiferous. In a soil formed from the accumulation of the refuse of the nearest dust yard deposited in excavations made for brickmaking or a gravel pit, the foundations of the drains are laid, literally, for little more is done than to deposit the bricks and pipes in the channels roughly dug for them; the timbers and flooring are put in within a few inches, if not actually upon, the ground, and the house run up of the cheapest material, and in the most expeditious manner; the object of the builder being in most cases to build for sale and not for investment. In a short time the ground settles, the drain pipes break, and the walls crack. It is not surprising that these buildings prove nests of fever, disease, and death. We could point to rows of houses in some of the naturally healthiest suburbs from which fever is never absent, and we may say never will be, and we are disposed to regret that act. District surveyors have enforced attention to the provisions of the Building Acts. Can nothing be done to stay this? The law precludes them from building within a certain distance, but it does not prevent them from extending the outbuildings, nor preclude the use of porous bricks, rotten timber, nor mortar made from the scrapings of the adjacent road. As a result we have houses which are filled with the exhalations from the sewers, walls which neither keep out rain nor wind—indeed some, we are assured, are only held together by the moisture retained in the brickwork. We have ourselves lifted the bricks from walls built seven years before without the slightest particle of mortar adhering to them. Yet it is such buildings as these we see inhabited in the suburbs, the creation of which is encouraged by the building societies, and not restrained by the provisions of any Act of Parliament. Until rows of them fall or are blown down we fear nothing will be done, and we shall continue to read in the Registrar-General's report the deaths of hundreds of victims of fever propagated by the gross carelessness and cupidity of those who are described as interested in the building trades.

Royal College of Surgeons of England.

The year of revolution, as Mr. Hancock seemed to think 1870, in his Introductory Address, has nearly passed away, but many a reform of the College of which he is Vice-president remains to be accomplished. In August it was resolved by the Council of the College "that not less than half of the members of the Court of Examiners shall be Fellows who are not, and have not within twelve months, been members of the Council, and that this resolution be carried out *as soon as possible*." The italics are our own.

Now it is generally feared that the resolution is in danger of being ignored—that the change will not be effected "as soon as possible." We have no wish to use hard words. Last year a very esteemed member of the Council took us to task—privately of course!—for the severe tone and harsh expressions of one of our staff in reference to this College. Nothing can be further from the intentions of the chief editor of this journal than to speak with disrespect of any gentleman in the Profession who has secured by his worth the suffrages of a great body of his brethren, and we do not unfrequently soften down the tone of articles supplied by those who feel indignation as they write. On the other hand the Medical Press prefers to call a spade a spade, and we shall not hesitate to stigmatise in strong terms what may appear to us disgraceful conduct, even though it be enacted by those in high places.

There are plenty of "good men and true" outside the magic circle. The vacancies will soon have to be filled up. We do hope members of Council will consider the force of their own resolution and the strong feeling of the Profession, and will show how unjust are those who are already prophesying that another great job is about to be perpetrated.

There is another question that should come forward. Are the Fellows at large—aye, the Fellows and Members too—to be suffered to elect the representative of the College in the General Medical Council? This has long been desired. Every true medical reformer has admitted that in this particular College the scheme of Dr. Prosser James could not fail to work well. We have fairly supported that gentleman on all occasions when it seemed likely to assist, and we were glad to see that at the meeting of Fellows and Members in the College, in reference to the late Government Bill, there was almost entire unanimity on this point. The question is once more cropping up. Men who have lagged behind are stepping forward to take credit for a plan he has advocated for years, as they now see that in that plan lies the chief hope of collegiate reform. They seem anxious to make what they can of it, and we as journalists may be glad of any assistance they can give it, though we shall not imitate them in grasping at the honour due to another. Nothing can rob a true reformer of satisfaction at the ultimate success of his plans, although it not unfrequently happens that those who have borne the burden and heat of the day quietly retire when they find those who were long apathetic, if not hostile, rushing forward at the moment of victory and noisily claiming the honours of the contest. Alas! that even our Profession should abound in injustice and self-seeking, and that those who set the best example of unobtrusiveness and self-sacrifice should find years of labour rewarded by the consciousness of having contributed something to the common good,—to be remembered when death has removed them from the scene, or when new toils, or worse, declining health, may render them indifferent to gratitude.

The Autumn Weather and the Wounded.

We understand that the wounded in France already evince symptoms of sympathy with the decrease in the temperature of the nights, for, notwithstanding the mildness and genial nature of the day-time weather, the nights are cold and ungenial to the wounded. We believe the authorities are deficient in those essentials which have for their object the artificial generation of warmth, as vapour baths, hot air apparatus, earthern water jar appliances, *et hoc genus omne*. No country is richer than England in these, so that we recommend an order to be given at once to one of our pottery agents for the immediate manufacture and direct exportation of a sufficient quantity of hot-water jars for the feet, &c. These are much less expensive than bed-pans and metallic warm water appliances, and equally efficacious. For the want of these rough and comparatively inexpensive requisites we hope the poor wounded men will not be permitted to suffer; but, on the other hand, may be freely supplied with what is at once a luxury and a requisite by generous-hearted Englishmen.

Vesuvius is threatening another eruption.

Royal College of Surgeons, Ireland.

We regret to learn that a temporary indisposition has induced Mr. James Barker to resign his seat on the Council of that body which he has so long and faithfully filled. Dr. Mapother, Professor of Physiology, seeks the vacancy, for which an election will be held on the 3rd November.

The Poor-law Board and St. Pancras.

At the weekly meeting of the Board of Guardians, a communication was received in reference to the proposed special inquiry into the charges which have been preferred against Dr. Hill, the medical officer of the workhouse, in which the Secretary of the Poor-law Board says, "I am directed to state that the Board are not aware of any legal power which the Guardians have to authorize the committee to summon witnesses so as to compel their attendance before the committee, and that the Board are only enabled to sanction the payment of the expenses of witnesses who may attend to give evidences at an inquiry instituted by the Board or conducted by their inspectors, for which special provision is made by the Acts 4 and 5 William IV., cap. 76 sec. 14, and 10 and 11 Victoria, cap. 109, sec. 21.—I am, Sir, your obedient servant, Francis Fletcher, Assistant Secretary." Mr. Parson informed the Board that the committee had held a preliminary meeting on the previous day, but declined to proceed until they ascertained if they could pay witnesses. After this communication, he thought the functions of the committee must cease, and an official inquiry be held. Mr. Watkins considered at first an official inquiry would be best. He could not call five medical men to give evidence unless their fees as witnesses were guaranteed. Mr. Salter remarked that if Mr. Watkin's witnesses, as medical men, came forward in the interests of the public, they could do so without making a market out of the parish. After some personal observations, the question that the Poor-law Board be requested to hold an official inquiry was put, and negatived by a majority of eight to six.

Leave of Absence for Medical Officers.

Paragraph 682 of the "Queen's Regulations and Orders for the Army" is to be amended as follows:—

"682. Applications for leave of absence for medical officers are to be made in the following manner:—I. Medical officers not attached to regiments are first to obtain the permission of the military authorities of the district in which they are serving, and are then to apply, through the principal medical officer, to the Director-General of the Army Medical Department, who will forward the application to the Adjutant-General, by whom the grant of such leave will be notified to the district authorities, and to the Director-General, who will inform the officer (through the principal medical officer). II. Medical officers attached to regiments are first to obtain the permission of the principal medical officer, and are then to apply to their commanding officers, who will forward the application to the district military authorities for transmission to the Adjutant-General, by whom the grant of such leave will be notified, through the district authorities, to the regimental medical officer. Officers commanding, in recommending medical officers for leave of absence on private affairs, will be careful to ascertain that the distribution and state of health of their corps, as well as the arragements for the carrying on of all the regimental medical duties, are such as to justify their recommendation. All applications are to be on W.-O. Form 1,119."

Ochlesis in France.

We regret to learn that our brethren engaged at the French hospitals are troubled with a form of erysipelas, which exists amongst their patients depending on the miasmatic generated out of the effluvia arising from the skin and breath of so many crowded together—a form of erysipelas which was called by Dr Gregory *Ochletic* (from ὄχλος a crowd) *Erysipelas.* There is little chance for patients with sores or open wounds where this exists. Surely convalescent homes might be obtained for those able to leave the hospital, or rooms set apart for what we have no hesitation in calling *Ochlesis,* for the information kindly given to us indisputably proves that such a form of erysipelas, as that we mentioned, will never yield to treatment, but be sure to extend its ravages by propagating its influence even to the most healthy of the men who may have the evil fortune of occupying the same ward. It behoves those of our philanthropic brethren, who not only interest themselves in the care of the wounded, but take upon them the superintendence of everything pertaining to the comfort and welfare of the injured and diseased, to influence the authorities at once in rectifying overcrowding and the occurrence of *ochlesis.*

Queen's University of Ireland.

The clinical examinations have been conducted in the South Workhouse Hospital, the medical officers of which most courteously aided the Examiners in Medicine and Surgery. Thirty-two candidates sought the degree of M.D., and twenty that of M. Ch.

The Eyeless Fish of Kentucky.

The Dublin Zoological Gardens have several of these remarkable creatures living in their aquarium. It is hoped that they may breed, and that eyes may become developed as the animals enjoy the light. The etiolation and transparency of their bodies are very well marked.

Clinical Examination in Dublin.

The Queen's University in Ireland has been engaged last week in the carrying out, as a part of its examination for medical degrees, the clinical, or bed-side test, and, while we give the University the highest credit for having been the first to introduce this form of examination into Ireland, we cannot but think that the system adopted for the purpose is very imperfect. The medical clinical examination is held at the South Dublin Union Workhouse, while the surgical cases are selected from some of the metropolitan hospitals, and are brought to the examination hall for the purpose. It is plain that a workhouse hospital cannot supply suitable subjects for examination. The fact that sick persons are within the walls of a Dublin workhouse is sufficient proof that they are too chronic for the wards of any of the numerous hospitals. In the same way, the cases which it is possible to convey across town to the place of examination are obviously not those on which the skill of a candidate can be satisfactorily proved, and we, therefore, are of opinion that a clinical inquiry restricted to such cases is not, in the real sense of the words, a bed-side examination at all.

The new ophthalmic wards at St. Bartholomew's are now in working order.

An Irish Double Diploma.

A few weeks since we had occasion, in reviewing Sir John Gray's Return of the number of degrees granted by licensing bodies, to point out the intimate dependence of the Colleges of Physicians and Surgeons in Ireland upon each other, and the circumstances which have constituted them natural allies in the licensing of a majority of Irish practitioners.

We were enabled to show from the official statistics that the greatest proportion of the licences in medicine granted by the College of Physicians were held by candidates who had already become Licentiates of the College of Surgeons, and, therefore, if the College of Surgeons were to cease to exist, or if for any cause its Licentiates should be induced to seek their medical qualification elsewhere, the College of Physicians could look with no hope to other Irish licensing bodies for a supply of candidates for its degrees.

We recapitulate these facts as a cogent hint to the authorities of both Colleges, that their mutual interest lies obviously and vitally in co-operation for the purpose of providing a joint diploma capable of maintaining, in their own country, the numerical superiority in licensing, which is, under the influence of disunion, in danger of being lost. It is hardly necessary for us to point out that each of the Irish Universities now grants what amounts to a double diploma, and that the attraction of a single examination for both diplomas has had the effect of increasing the number of degrees granted within five years by nearly 100 per cent., and the Colleges must be sanguine if, with those statistics before their eyes, they adhere to the view that students will be content to undergo two separate and distinct examinations, and to pay double fees for the satisfaction of writing L.R.C.S., L.K.Q.C.P. after their names.

If the question of the creation of an Irish double diploma be approached in a liberal and unprejudiced spirit by both Colleges, there appears to us to be little subject for dispute between them. It is no slight to the College of Physicians to say that it cannot hope to meet the College of Surgeons on absolutely equal financial terms. The College of Surgeons has been for more than half a century, and, despite of increased competition, still remains, the Surgical Licensing Body of Ireland. Its museums and libraries are the recognised centres of reference of the Irish profession, and candidates for a place in our ranks have been ready to pay for its *imprimatur* a higher fee than for the seal of any other body. It is obviously entitled to expect that its public establishment shall not be put on short allowance for the purpose of co-operation with other bodies, and, this principle being admitted, we believe that no insuperable difficulty need interpose in the settlement of a question which the profession looks upon as vital to the future of medicine in Ireland.

The late musical festival at Birmingham raised £6,000 for the General Hospital.

Mr. Hammond has resigned his office of Surgeon to Addenbrooke's Hospital, Cambridge.

Dr. Maudsley is to preside at the next annual meeting of the Medico-Psychological Society.

The Medical Society of London will meet on the 17th. The Clinical on the 14th.

The fever at Liverpool continues. An inspector has been sent by the Privy Council. There were 326 new cases admitted into the hospital last week.

We hear sad accounts of what is called yellow fever on the Spanish coast. Cholera does not decrease at Kertch. What with war and pestilence, Europe is now suffering sadly.

The Southern Hospital at Liverpool is in want of £1,700 or £1,800 to complete its new buildings, and the Northern Hospital is about £1,800 in debt. We hope an effort will be made to raise the whole of these sums quickly. We hear that the Bishop of Chester is ready to take up the cause, and that something is likely to be done. Liverpool is not poor, and her medical charities deserve support.

Correspondence.

QUEEN'S UNIVERSITY DEGREES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the article which appears in The Press of September 7th, you state the number of degrees conferred by the different licensing bodies in Ireland. The Queen's University granted fifty-one in 1869, and thirty-one in 1865.

In October, 1867, there were, I believe, at least eighty candidates for the first half, and nearly the same number for the June examination. In October, 1869, there were only thirty candidates for the second half, one of whom was a surgeon in in the Indian Army, and two others were previously qualtfied.

What became of the fifty other candidates for the first half in 1867, and who should have gone in 1869, and whose services go to Edinburgh for their surgical diplomas, merely on account of the examination—practical surgery?

You appear to scoff at the £5 degree; we really thought at the present day education was not valued at what it cost, but of its real merit. I, for one, should be very sorry to give the Dublin College of Surgeons £28 for its diploma, besides having to attend three courses of surgery—two being quite sufficient.

I am glad to find that the Queen's University was the first to institute an examination in practical surgery, also in anatomy. The next (a fact of which I am fully aware), to come of the other licensing bodies, where the examination in chemistry and natural history is merely nominal, in fact, are never asked a question on these subjects. Physics and the examination in practical anatomy by dissection appears to be a very sore point with those accustomed to the "grinding" system and "tips." With regard to the M. Ch., the candidates were really afraid of the practical examination, which is required as a test since the degree was first conferred by the Queen's University, and is not merely nominal, as at some of the purely surgical bodies, and I knew some men who got good places at the board of dissection, and in clinical medicine. Perhaps these are the blandishments of which you speak.

I forgot to mention that there were between eighty and ninety candidates for the first half in October, 1869.—Yours, &c.,

"M.D."

"UPON MATTERS PROFESSIONAL AND GENERAL."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It does an Englishman good to shake hands now and then with an Irishman. On physical grounds I base my argument with a hope of averting pathological phenomena, having to be recorded in the way of autopsy.

The Irish shillaleigh, an out spoken token of tender regard, when properly shown, is one I can assure you regarded with proper respect and esteem on this side of the Irish channel.

It is known in our metropolis, and is now well appreciated in our provinces, that an Irish doctor after all is no bad fellow. I remember the time when I read many years ago in the Medical Circular, at the foot of an advertisement, for an assistant or *locum tenens*, "no Irishman need apply." Is it so now? Is Ireland ashamed of its masters in the art and mystery of medicine or surgery; or on the other hand, is England abashed at receiving, adopting and baptising into brotherly fellowship, men who have carefully studied in Erin's Isle? To both questions and to both hypotheses I say emphatically, no! I repeat my axiom by saying it does an Englishman good to shake hands with an Irishman. Now about the "Roasted Apple Association" of which company I happen to be a shareholder, under the limited liability act, fortunately perhaps for you as well as myself. Inasmuch, that a civil action at law will not lie, and that assessed damages will not weigh heavy. The British Medical Association number in its ranks upwards of four thousand able bodied hard-headed medical men, who love their profession for its own sake, and who were grafted into the craft, not only in England, Ireland, and Scotland, but in lands far across the seas. I think almost every clime owns an indigenous medical or surgical plant nurtured and potted out in good loamy British soil, after having been kept by us during the winter frosts of its infancy. Now, why should not England and Ireland continue to work, hand in hand, as nursery men or nursery maids, to educate skilled surgeons and physicians? The main object of the British Medical Association is to embody medical men from all parts of the globe into one central mass, and to do this it must necessarily have a speaking trumpet of its own, an organ I ought to have said, which organ is called simply and purely *The British Medical Journal*, a journal which should be a credit to England, Ireland, and Scotland. Now about postages and I cease.

The Postmaster-General is laying down hard lines if he prevents you from stitching your paper before you post it. I have had many times to congratulate you on sending your Medical Press and Circular out with its pages already cut and ready for reading, which never has been the case with the *Lancet, Medical Times and Gazette, or British Medical Journal*, but now the Postmaster-General pops in and forbids an interchange of medical journals, with my two medical brothers who happen to live two hundred miles away from me, I find in earnest I have a real *casus belli* against him, which I doubt not *you* and *I* will be able with time and patience to combat, overcome, and conquer.

I am Sir, yours respectfully,

John A. Bolton, M.D.

Leicester.

SCARLATINA—IMPORTANCE OF ATTENDING TO THE FUNCTIONS OF THE SKIN AS A MEANS OF LESSENING ITS MORTALITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

Sir,—I am almost of opinion that a copious eruption is as little to be desired in scarlatina as in small-pox. An epidemic of that disease, has prevailed in Cappoquin for some months past, and, with the exception of one child that died with it of diphtheritic croup, there was no fatal case. Most of the children got well in four or five days. There were no sequelæ. This I attribute to the fact, that the rash was a mere blush, often barely discoverable by drawing the finger over the skin, and observing the white line track it left. There was little heat of skin, and scarce any desquamation, what there was being a minute brawny scaling away of the epidermis, more like that of measles than scarlatina. In previous fatal epidemics of scarlatina, the skin, I noticed to be of a fiery redness and heat, and that the cuticle all over the body became coriaceous, as if tanned. We know that we can produce albuminuria and its concomitant ills in an animal, by glazing over half or three fourths of the surface of its skin. To do so completely, would cause speedy death from asphyxia. This consideration shows that, to preserve the integrity of the epidermis should be our main object in the treatment of scarlatina. Cold affusions or sponging do something. Inunction with fats does both good and harm. The wet-pack of the hydro-therapist more completely attains the object in view.

F. M. Luther, M.D.

Cappoquin, 26th Sept., 1870.

THE MEDICO-SURGICAL PROFESSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is perfectly correct that the professors of the medico-surgical profession, should buoy up the hopes and prospects of student at this commencing period of study at the various hospitals. Now a little truth is necessary. Does a student enter on his study for ultimate living, or science; many doubtless do for either or both. I have watched the career of over a dozen youths during the last quarter of a ceutury. Half went in for medical "business" some call it trade, and all did well in a pecuniary point of view; agreed with everybody and everything, physic at a discount. The others went into the "science" of the profession, high noble science, supposed to lead to immense results, emoluments and everlasting fame: two only out of the "great talent" made any stir in the world, but all succeeded in poverty. Now sir, which is which, physic-trade, or physic-science. In my experience no student should enter the portals of the medical profession for science sake, extended as I grant it is over divinity or law, except he starts on £500 a year at least, clear income.

Yours respectfully,

A QUARTER OF A CENTURY MEDICAL KNOWLEDGE.

4th Oct. 1870.

P. S. Your medical journal never burks the truth, is my reason for addressing the students through it.

CHLORAL HYDRATE IN TETANUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The history of the following case conveys a practical lesson of the inutility of an over-estimated drug, in the treatment of a very distressing complaint—traumatic tetanus. Time after time there have appeared in the Medical journals, records of the most wonderful cures perfected by this comparatively new preparation—chloral hydrate. Pictures only too highly coloured and calculated to provoke the question, whether some other drug of the same sedative order might not have been equally efficacious in overcoming the paroxysms of tetanus.

On the 17th September, I was requested to visit a man, whom it was stated, was suffering from quinsy. When I got to the house, I found my patient, a man of three and thirty years of age, lock-jawed, from himself I could learn little, the paroxysms of tetanus were frequent and severe, the head was drawn back and the chest directed forwards, so that to relieve him, the occiput had to be pressed forwards and the chest backwards. Upon examining the spinal region, I discovered the seat of mischief which existed at the lower dorsal region. It appeared when at work in a colliery pit, he sustained a punctured wound of the spine, no attention was paid to it, since little pain was suffered from it, until the commencement of the tetanic symptoms.

The wound was probed and dressed, and belladonna extract rubbed around the wound and along the spinal column; the bowels were well cleared out, and I gave him full doses of bromide of potassium, tincture of belladonna, and camphor julep in mixture, under this treatment, the paroxysms became subdued in character and diminished in number, as he did not sleep at night I exhibited two drachms of Ferris's syrup of chloral, which is equivalent to twenty grains by weight of the drug. The man was in a "Field Club," and to his friends appeared improving, so that when they went to give notice of his illness they were informed they must have a certificate from the field doctor. This gentleman, a person named Stanford, came, took charge of my unfinished case, and held it two days, until the symptoms returned so alarmingly, that I was again requested to renew my treatment. The paroxysms were now frequent, and the sufferings of the unfortunate man truly great. I gave him two drachm doses of the syrup of hydrate of chloral every two hours, increasing it to four drachms, but without the slightest effect, one way or the other. A strong belladonna enema appeared to arrest the paroxysms for a time, but they only returned with renewed and aggravated severity, *I now exhibited the chloral every hour, narrowly watching its action, but it produced no more therapeutic effect, than so much simple syrup might be expected to produce.*

The unfortunate man died on the seventh day. A *post-mortem* examination was denied me. My case proves two things. 1st. That in traumatic tetanus, hydrate of chloral must not be depended upon. 2ndly. It teaches the imprudence and danger of medical men presuming to undertake the management of unfinished cases, without a consultation or some understanding given by the man first in attendance. Although unjustifiably superseded because of some paltry club arrangement, I was only annoyed and grieved to think my patient, who clung to me with that strange mixture of freshly-lighted affection and confidence so encouraging to the practitioner, for I never saw the man before, should have been injured by a change in treatment, for in tetanus forty-eight hours is a serious loss of time.

In an editorial article, you, sir, suggested an important arrangement which should exist in the rules of every club, that the men should select, in time of illness, their own doctor. My present communication proves the necessity of such an arrangement—the absurdity of forcing a man on the people, *à la mode* the Duke of Buccleuch, is simply disastrous.

I am Sir, yours truly,

J. WARING-CURRAN.

September 28th, 1870.

WILL-MAKING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I consider every medical man, if required, should be sufficiently skilled in legal matters to be able to draw out a document, and have it properly executed, as a will, that shall stand good as such in the eye of the law. I believe it should fall to the lot of every lecturer on medical jurisprudence to teach his class this important essential; for the ignorance of the Profession on this subject is truly great, and, comparatively, very few indeed are competent to make a will; this we have exemplified every week in our Law Courts One time we have wills made with witnesses to the signature or mark, as the case may be, legatees as well; again, I have seen wills without the appointment of executors or an executrix; I have heard of the testator signing the instrument, or affixing his mark, without the document being previously read over and explained to him, and the witnesses to it not signing in the presence of each other. Wills thus illegally drawn and executed have been the means of preventing probate being obtained, and much injustice thereby done to the survivors, and the last wishes of the deceased frustrated, owing to the incapacity and ignorance of the man who took upon himself the responsibility to prepare it. When there is time, the duty belongs to the solicitor; but when danger is imminent, and a dying person desires either to make a will, or revoke a former one, and solicits his attendant to perfect the matter forthwith, at least he should be competent; yet how few are able to do it. There is one point I earnestly direct attention to, and I beg our brethren will adhere to it, that is, never to take instructions respecting the disposal of property from any other than the testator himself or herself; to carefully pencil down their intentions, and after re writing in proper form, to read it over word for word, carefully explaining every item as bequeathed to each legatee, and making the document thoroughly comprehended in simple language by the testator. To draw up a will upon the suggestions of others; read it over to a dying man, only too ready, perhaps, to be spared worry and bother, to give assent, is cruel and criminal. There are few medical men who will not, in the course of practice, be appealed to, to perform this simple duty; yet, however simple, many remain in happy ignorance of the method of doing it, and when they attempt it, only baulk their best intentions, whilst they injure those whom they hoped to benefit. I am, Sir, your obedient servant,

NEPENTHE.

Sept. 28th, 1870.

Substitute for the Forceps.

A BRITISH medical officer travelling in India, met with a case of labour requiring the forceps. Not having any instruments at hand, he sent for some dancing-girls, and selecting the one with the smallest hands, caused her to introduce them after the manner of forceps, and so to effect delivery.

Medical News.

Metropolitan Poor Law.—Mr. Goschen, the president of the Poor-law Board, has addressed a circular to the guardians of the London unions, drawing attention to the Metropolitan Poor Amendment Act of last session, which provides for the equal distribution over the metropolis of a further portion of the charge for the relief of the poor, by making a large part of the cost of maintenance of the in-door poor a charge upon the metropolitan common poor fund, from the 29th of September last. In this letter the intent and meaning of the act, and the mode of carrying its provisions into effect, are set forth at length as a guide to the official bodies and other persons upon whom devolves the duty of administering the law.

Madras Medical Retiring Fund.—The following official notification has been made:—"The managers of the Madras Medical Retiring Fund having formally made over to the Right Hon. the Secretary of State for India in Council the assets, records, and other property, liabilities, and management of the fund, in terms of Act 29 Vict., cap. 18, with effect from Sept. 1, 1870, it is hereby notified that the Government of India has been pleased, on the part of the Right Hon. the Secretary of State for India in Council, to accept the transfer in terms of the aforesaid Act, and with effect from the date above specified. The Government of Fort St. George will be pleased to issue the necessary subsidiary orders on the subject."

Cambridge University.—The Downing Professor of Medicine or his Deputy will deliver a course of lectures on Materia Medica, Pharmacy, and Therapeutics during the ensuing Michaelmas and Lent Terms. The lectures will be delivered in Downing College, on Tuesdays, Thursdays, and Saturdays, at nine a.m., commencing on Tuesday, Oct. 25. Fee for the course 3*l.* 3s. The museum of Materia Medica at Downing College is open daily to all students of medicine.

Army Medical Department.—Staff Surg. Holahan has been ordered for duty at Linenhall Barracks, Dublin. Staff Assist-Surg. Kearney has been granted leave of absence, pending embarkation for foreign service. Staff Assist-Surg. Coney has been ordered from Dublin to Ballina, and Staff Assist-Surg. from Ballina to Boyle.

Aid to the Sick and Wounded.—Intelligence received by letters brought by the American general, Burnside, to Versailles, and from thence sent forward to London, announces that the American International Ambulance is perfectly organised, and in working order; large numbers of the American gentlemen and ladies remaining in Paris are enlisted in the service of this the only American ambulance organised in France. This ambulance has as its surgical chief a most distinguished surgeon of New York, Dr. Swinburne, and a large staff of medical and surgical officers. Dr. Thos. W. Evans, Dr. Edward A. Crane, Secretary.

NOTICES TO CORRESPONDENTS.

A Member of the Medical Club.—The Annual General Meeting takes place this afternoon (Wednesday 12th.) at three o'clock. As you live in town you can easily attend, and will then obtain all the information you want.

University College.—We have received the Calendar of this hospital, a most useful volume to which we have referred some parents and guardians. We wish all our institutions would send us such a calendar. It does not go into the waste-paper basket like a prospectus.

L.S.A.—Such a diploma would be of no value. As for ornamental purposes it might provoke unpleasantness. Go in for the College of Surgeons.

Salas.—The journal in question took up the subject after the Medical Press. It has often imitated us in this way. The boast to you was of about the same value as many of the editorial paragraphs that adorn our "tradesmanlike contemporary," but we do not care to notice it, and, as a rule, have no desire to trouble ourselves about the conduct of other journals. We have lately refused several articles exposing our contemporaries or reflecting on their staff. We do not know if the gentleman who has offended you still writes for the paper. The writer of the leaders in the Medical Press which you so much admired, has done nothing for us since, but he will soon rejoin our staff.

F.L.S.—Oliver's "Outlines of Botany" published by Macmillan and Co.

PATENT SURGICAL SILK CORD.

We have received a sample of this substance made [by] Messrs. Arnold and Sons, and can strongly recommend it. We hope some of it may be sent out to the French at the Seat of War. It is made of pure silk, without colouring or any of what is called dressing, and when used it does not twist or curl up like ordinary silk. A very convenient way for surgeons who only want small quantities, is to order one of the small tablets in a case which gives thus four sizes.

J. S. T.—We are sorry to be unable to comply with your request. The proceedings were too lengthy to enable us to do more.

F. B.—Our columns are freely open to fair discussion, but we must ask you to let your letters be brief. We cannot admit the personal attack contemplated.

POST OFFICE REGULATIONS.

We are restrained by post officials from stitching the journal, and must, therefore, ask those numerous subscribers who write about this to make their complaints to the Postmaster-General. It seems quite absurd to prevent proprietors turning out their journals in the neatest possible form. But red-tape stops the way. It is just the same with the new halfpenny post cards. Some correspondents have posted plain cards to us with a halfpenny adhesive stamp affixed. In every case we have had to pay one penny fine. Others sent us some newspapers with the old impressed stamp on the first of October, we had to pay twopence each. The Post office seems bent on doing all it can to neutralise the benefit gained, and yet is behaving most shabbily to the letter-carriers. When will common sense find admission to official circles? Oh! for another Rowland Hill.

Cucumber.—The annotation appeared in our columns last July to which you refer. The verses referring to our article in *Punch* are, as you say, "well done."

Glitter.—We meant all we said. It is vulgar this professional trading in the horrible events taking place in France. Whom the cap fits, &c.

Podalirius.—The paper is beneath our notice. Write to the Council of Management, and lodge your complaint with that body.

Cantharides.—Your letter is simply libellous. We must not print it, but we sympathise with your honest intention.

Medicus.—See Professional Calendar.

J. L. D.—Many thanks for your kind interest in the matter of new subscribers. We have inserted the name upon our list, and the journal will go regularly to the address given.

LONDON MEDICAL AND SCIENTIFIC SOCIETIES.

The first meeting of some of the Societies takes place during the present week. At the Royal Microscopical Society, this evening at 8 P.M, Dr. G. W. Royston Pigott will read papers "On Aplanatic Illumination," and "On Aplanatic Definition, with Optical Illustrations." On Friday, at the Clinical Society of London, at 8½ P.M., Dr. John Harley, "On a Case of Injury to the Liver." Mr. Spencer Watson. "Four Cases of Parenchymatous Keratitis, associated with Acute Rheumatism." Dr. John Ogle, "On a Case of Tetanus treated with Ice and Belladonna." And other papers.

On Saturday, the Medical Officers of Health Association meet at 7½, when an Address by the President Dr. Druitt, will be given "On the Sanitary Topics of the day."

BABY-FARMING.

Our esteemed correspondent "Dr. J. Waring-Curran" in striking at the root of this great social evil, advises that the *seducer* should be made amenable to legislation, and be punished according to the nature and strength of the evidence adduced at the trial. While seduction is condoned for by the payment of 2/6 weekly, infanticide and baby-farming will exist.

THE HOOK TO CATCH FISH.

To the Editor of "The Medical Press and Circular."

Sir,—I have been frequently asked by lady patients in an interesting condition about a book which is frequently advertised *Parturition without Pain or Loss of Consciousness*, published by Robert Hardwicke, 192 Piccadilly, and I have had to shake my head in ignorance of some hidden discovery, for the writer is of us.

The lady superintendent of a large school writes to me to-day for information respecting a book entitled, *Scarlatina, its Prevention by Belladonna and Carbolic Acid*, published by James Epps, of Piccadilly. Can I recommend it? I should like to see a review of either or both in your columns, because I fear they are hooks to catch fish. I hope I am wrong for the sake of the author's character, and those who may be lured to purchase what may be trash. Pardon the suspicion of an old practitioner, whose conscience age has rendered very scrupulous.

Your obedient Servant,

Chesterfield, Oct. 8th, 1870. Dum Spiro Spero.

SPLENIC APOPLEXY (?)

To the Editor of "The Medical Press and Circular."

Sir,—I read in common with some of my friends, simple, ignorant, country folk, a little sensational blank shot fired off on the subject of a *very fatal, most disastrous* and *much to be deplored* disease—splenic apoplexy—attacking cattle fed upon sewage-irrigated (not *irritated*) land. In this year 1870! Above all other years, when was this rank, rich, poisonous grass grown so abundantly? The writer makes an error, he meant *splenic atrophy*, for the poor beasts suffered enough for the want of pasture, and there is no use slandering them in saying that they had too much. "Here is a halfpenny," said the charitable-disposed to the errand-boy, "and don't buy sweetmeats to make yourself ill." Well might the poor oxen who have been half starved all the summer, retort—*Sic vos non vobis fertis aratra boves.*

Your humble Servant,

Oct. 5th, 1870. A Country Doctor who hates nonsense.

INDECENT MEDICAL ADVERTISEMENTS.

We are glad to find the *Nottingham Journal* directing public attention to the abominable character of certain filthy [medical advertisements published in the columns of its local contemporaries. "Paterfamilias," in a clever letter addressed to the Editor of the *Nottingham Journal* informs us that the papers engaged in the nefarious trade infringe a bye-law of the Corporation, rendering them liable to fine or imprisonment. The bye-law to which the writer refers runs as follows:

"Every person who shall deliver to any inhabitant or passenger in or near any thoroughfare in the borough, any posting bill or printed or written paper of an obscene, indecent, or offensive nature, or referring to any disease of a loathsome or secret kind, or to any secret cure for any disease, shall forfeit and pay for every such offence a penalty not exceeding the sum of twenty shillings."

We wish all corporations possessed the same judicious law. We heartily endorse the following remark of "Paterfamilias," which are quite *apropos* to the subject.

"The Sanitary Committee keep a strict watch that putrid or diseased meat shall not be sold in the Shambles as sound food, and that nuisances affecting the physical health of the people shall be at once abated. They cannot refuse when their attention is directed to the subject to exert their authority to put down this dreadful moral pestilence, and if they persist in continuing the publication, punish those who encourage it for their own pecuniary profit."

The Medical Press & Circular.

FEIGNED INSANITY.

By J. H. Balfour-Browne, Esq., Barrister-at-Law.

If the law has been slow to adapt itself to what may be regarded as the results of modern science, those persons who are the exponents of what the results of modern science are have themselves to blame. If the definition of legal irresponsibility is such that it is calculated to suffer the punishment of many who ought to be exempted from the consequences of their criminal acts, it is so in consequence of the thorough incompetence of many medical witnesses to distinguish between real and feigned insanity. To demand that the law should sail close to the wind of science, which seems at best to be a wavering draught or squall, is to demand too much. The judges very properly decided, as it seems to us, that it was better to have too narrow than too broad a definition of legal insanity; that it was better for the interests of the community that some persons who might not in strictness be responsible for their acts, should suffer punishment for their misdemeanours, than that many, who were really responsible to the laws, should, through too wide a definition of insanity and the incompetence of those, who in individual cases were summoned to say whether insanity was real or counterfeit, escape the merited punishment of their crimes. And the judges were right. Until very recent times medical men were not in any way trained to a knowledge of insanity; and where members of the Profession who might have obtained some reputation in other branches of the profession, were placed in the witness box to give evidence, as to the mental condition of a person accused of a crime, it can be easily understood that their evidence was most unsatisfactory. Even at the present day the precaution taken by medical educational institutions and examining boards, that those to whom they give degrees and licenses should know something of insanity, are most defective. We are glad, however, that one or two of our largest and best conducted hospitals for the insane now give opportunities to medical men to become practically acquainted with the symptoms and treatment of mental disease. And a day may come when the word "expert," as applied to those who profess to be informed as to the important questions of medical-psychology, may lose that tinge of irony which, in the eyes of lawyers, at present, attaches to it. That the law has been slow to adapt itself to recent scientific knowledge in relation to mental disease, is due to the fact that the medical profession has not, as a whole, adopted the results of those investigations, and that at the present time the knowledge of insanity diffused among the ordinary ranks of the Profession is thoroughly inadequate. Any one who has taken the trouble to examine the medical certificates, upon which, under the present law, lunatics are confined in asylums, must have been struck with the slovenliness and ignorance of those who filled up the printed form. In the first place, those medical gentlemen, in many cases, seem either to ignore the existence of a rubric—which directs them what to do—or to be unable, if they do read it, to understand its perfectly intelligible requisites; and, in the second place, the statement of the "facts indicating insanity observed by myself," or communicated by others is generally most unsatisfactory. One medical man gave as the only fact indicating insanity, observed by himself—"Called me a fool," while another, evidently ignorant that "to drive unicorn" means to drive a team of horses, in a particular way, stated that the individual "believed he had driven a unicorn." Can it be a matter for wonder then that many members of the medical profession have found much difficulty in distinguishing between insanity which is real and insanity which is assumed, or that lawyers have been in general very suspicious as to medical testimony, and unwilling to take it for what in some cases might be its real worth. When there are many false coins going about, a good shilling may now and again be refused; and one is not to be blamed if they give every sixpence a "ring" on the counter. The way to remove the stigma is, in the first place, to remove the justice of it! The best way for the medical profession to begin

the reform is not to alter the law, but to see that it is in future better educated!

But how are we to detect feigned insanity? 1. In idiocy; 2. In imbecility; 3. In dementia; 4. In mania; 5. In partial intellectual mania, monomania, and melancholia.

1. *In Idiocy.*—It is well to remember that the greatest difficulty in the decision of the question as to whether an individual is feigning insanity or not, arises in consequence of the fact that many insane persons will, under similar circumstances, resort to precisely the same expedients as those who are sane. If a person who really is under the influence of an insane delusion sees that it is for his advantage that he should be thought insane; if he is aware that the belief in his insanity will exempt him from the consequence of some foredone act, the mere existence of an insane delusion does not preclude the possibility of his feigning an insanity under which he does not labour. This fact seems to have been overlooked by almost all writers on the medical jurisprudence of insanity. That this circumstance complicates the question is evident. Many of the tests which are in ordinary circumstances applied to decide the question—as the enquiry respecting the beginning of the insanity (the early symptoms of the disease being those in which feigners usually fail), the questions as to hereditary tendencies, as to previous attacks and the like—are, to a great extent, rendered useless. That the delusions of many persons are modified by motives, much less powerful than the above-mentioned, as, for example, by the questions and laughter of a little knot of listeners, we have often observed, and have found, that even to enjoy the pleasure of being laughed at, the pleasure of attracting notice, persons with many extravagant delusions would upon occasion exaggerate and vary the statement of their unhealthy impressions. In most cases, however, in which a healthy mind, or one which looked at in reference to the ordinary minds of mankind, may be looked upon as healthy, undertakes the task of feigning insanity, the difficulty of detection is not great. Two things are necessary to ensure a correct conclusion—care and time. Time fights for truth! Idiocy, then, is a form of mental unsoundness very rarely assumed, in consequence of the facility with which its genuineness can be ascertained. The history of the individual which can in these days be more easily traced than in times gone by will, in all cases show whether it is feigned or real. The form of the head is a symptom which cannot be feigned. No man by taking thought can take away that deformity any more than he can add a cubit to his stature. There are often other deformities associated with idiocy, and for those who have to decide a question as to real or feigned insanity, it is most useful to remember that those symptoms only which are quite beyond the power of the individual are, as it were, the rock on which to build their theory—for, after all, the answer to that question is a theory and nothing more—while the other facts, which must be had recourse to, are like the sand, and winds of doctrine may lay it in ruins!

2. *In Imbecility.*—But there may be great mental weakness, and the form of the head may not be indicative of the defect. In such cases the imbecility is not congenital, but acquired. The history in such cases is of the greatest importance, and the supposed cause of the enfeeblement should be very carefully sought for. In such a case the impostor would prove too much, by assuring us that he had been in his present condition since his birth. The cause assigned, and the nature of the malady, will in most cases of imposture discover the trick by the inadequacy of the one to the other. It is to be borne in mind that it is in reference to the "outside" facts of the disease that errors will ordinarily be found. All the acts which get out of the dominion of will, and become automatic, will differ in the case of an impostor and in the case of a real imbecile. The history of the case, as showing his opportunities for becoming acquainted with the symptoms of the disease, should be carefully studied. And yet due weight should in each case be given to the force which unconscious imitation is known to exercise over a weak mind. The physiognomical diagnosis of expression is a very important point in all cases in which simulation of insanity is suspected; and skill in this department of the work of the medical-jurist is only to be acquired by long and careful experience—to be best learned, it seems to us, in the wards of our hospitals for the insane. The description of a "look" is difficult. To say that the imbecile has a dull, stupid, vacant look is true; that his manner is uneasy, that his temper is variable, and that sometimes the dead level of his mill-pond existence is broken by a little eruption of passion, is likewise true. But the description would do for many other persons besides imbeciles. By careful watching, gleams of the smothered intelligence will shine through, or flash out of the impostor's face, and it seems to us that an experiment by means of the introduction of some object likely to excite curiosity or wonder into the presence of the individual suspected of imposture, would often serve to uncover the ambush intelligence. In many forms of imbecility there is a mixture of folly and acuteness. Many of the stories told in Scotland of their village fools, or "naturals," prove this; and the ordinary test that while the real imbecile is shrewd or foolish irrespectively of prospective interest, the impostor is shrewd in all matters connected with his scheme and its success, and shows his folly and stupidity only in connection with matters of indifference, is, it appears to us, unsatisfactory! One thing seems somewhat certain, and that is, that this form of insanity is not often assumed, first on account of the fact that this amount of imbecility, even when really present, is not necessarily incompatible with responsibility; and, secondly, on account of the difficulty of impressing individuals with the idea of insanity, and its existence in one who manifests many signs of intellectual activity. When this amount of unsoundness does occur, it is not unfrequently accompanied by sufficient self-control to enable the individual at certain times (when it suits himself) to appear perfectly sane. And when such an amount of self-government exists, the individual, whether labouring under mental defects or not, seems to be properly punished on account of a proved transgression.

3. *Dementia.*—Dementia may be, and sometimes is, simulated by aged persons. In most cases, however, it is not a sufficiently demonstrative form of insanity to find favour with impostors; and it is so imperfectly understood, and so commonly confounded with simple dotage, that its adoption is rare. The characteristic of senile-dementia is a deficiency of mental excitement; there is a torpor of all the faculties; in it the mind is like an engine working under defective pressure. One circumstance which has led to dementia being confounded with the defects of age is, that one of its symptoms is that memory loses hold of events near to the present in point of time, sooner than it does of those events which are more distant. Delusions which do come, fancies which take possession, are generally connected in some way with a substrate fact of the past life of the individual; and there is a gradual decay, which the impostor would find it impossible to simulate; indeed, one rule for the guidance of the medical-jurist in all those cases, might be:—Look always for gradual changes in cases of real disease; look for sudden transitions in cases where the will of the individual is attempting to take the place in the production of physical events—of the great slow laws of nature. This is a good rule! The will jumps—the laws of nature creep! The gradual decay above alluded to is marked by the darkening of that glass through which the senses, at best, darkly see! The power of recognising persons, places, and things goes, and there is no return. The mind lies in circumstances, like a water-logged ship in the waves. *Sans* everything! Even in this stage of the disease a man might commit crime, or, in other words, might do harm to himself or others. But little or no difficulty is likely to arise from attempts to feign senile-dementia in this its last stage. There is an actual repugnance in strong humanity to sink so low—to

seem so weak. After death Cæsar's clay may keep the wind from whistling through a chink, but not before. We find then, as a fact, that it is rather those forms of mental disease which arise from undue excitement that are chosen for imitation by impostors, than those which arise from defective development or diminished activity of the faculties. It is to be remembered, with reference to dementia, and our diagnosis of it, that where it is not the result of some severe mental shock, it is the consequence of organic disease of the brain, which almost invariably, in time, reveals itself in paralysis. So time fights for truth here too!

The remaining subjects—Mania, Partial Intellectual Mania, Monomania, and Melancholia, will be continued in our next.

ON ISCHURIA RENALIS.

By J. Waring-Curran, L.K.Q.C.P.I., L.R.C.S.I., &c.

My chief object, in narrating the history of the following cases, whilst I feel they are not devoid of practical interest in themselves, is to bring more prominently forward the employment of powerful diuretics in the treatment of certain forms of renal disease. Admitting, however hazardous such a method may prove, there is no disputing the fact that the description of case wherein I recommend the adoption of such a plan is universally fatal if not speedily relieved; and I thus open the question whether, after the failure of certain orthodox remedies to relieve formidable symptoms and effect excretion of urine, and death accordingly impending, we are not justified in falling back upon a treatment to which I regret the Profession usually says its *veto*, without first fairly, in suitable cases, testing its value and effect.

Dr. Elliottson refers to Sir Astley Cooper exhibiting powerful and stimulating diuretics in obstinate cases of suppression of urine, and men of the older school were in the habit of prescribing tincture of cantharides with the same intention, I may then be excused trying to revive what the most eminent at one time practised.

Case 1.—*Mixed suppression of urine, produced by mechanical obstruction, and terminating in renal congestion.*—Mr. E., a corpulent, previously healthy man, aged sixty-seven years, sought advice on the 22nd of September of last year. Before visiting him, I was informed he had been troubled with his water for some weeks; that he was in the habit of passing large quantities of gravel, and suffered a good deal with pain in the loins, for which he was treated by another medical gentleman. The day I first saw him he proposed going to London to consult Dr. Tanner, but as he had passed no urine for 24 hours, his family became anxious that he should have further advice before leaving home. He was walking about his parlour as I entered, and appeared the picture of health; discoursed freely upon other topics besides his ailment; and seemed a good tempered, lively old gentleman. I gathered from him that for some weeks he laboured under irritability of the bladder, frequent desire to pass water, burning pain over region of kidneys, and a sense of distension about the abdomen; that he suffered from nausea, occasionally accompanied by vomiting. The conjunctiva was tinged, and the surface of the body presented an icteic hue. He did not impress one with the idea that he suffered much if the face be indicative of such phenomenon. There was no tenderness over either kidney, and the pain he said was of a dull, heavy character, passing along the inside of the thighs; the tongue was dry at top and along edges; the pulse beat at 76; there was slight nausea; loss of appetite, and insomnia; but there was no retraction of testicle, no uneasiness at end of the penis. The temperature of the body was 105° F in the axilla. I was unable to detect the presence of fluid in the bladder. I ordered some linseed and mustard poultices over the kidneys; prescribed a saline mixture with belladonna, and exhibited some compound jalap powders. At bed-time I recommended warm hip baths to be used, and promised to see him early the following day.

The friends appeared surprised at the attention I bestowed to every symptom, and could not understand my attaching so much importance to so apparently trivial an illness.

September 23rd.—Has spent a restless night; bowels have been copiously removed; passed a few drops of bloody water which merely stained the urinary apparatus, but walks about as on yesterday. Went before breakfast-time for a short walk. There are colicky pains over the bowels, sickness, and thirst. The man is restless and uncomfortable, but cannot express, he says, how he feels. I cupped him over the kidneys, and gave him a full dose of calomel and jalap, ordering the warm baths to be continued.

Evening Visit.—Much the same as in the morning, with the exception that he seemed brighter because of having voided about an ounce of very dark coloured, bloody urine—if I may call it urine—as it had no smell of it, and appeared pure blood. I suggested another opinion. His family named an eminent Nottingham surgeon, Mr. Thompson, with whom I consulted. He viewed the case in the same light with me, that the tubes of the kidneys were loaded with lithates, and that renal congestion supervened. I suggested a powerful diuretic, but Mr. Thompson who is a famed practitioner would not agree, and I acquiesced to the passage of a blood catheter, which drew off a few ounces of blood; to the exhibition of turpentine capsules, to drinking of gallic acid dissolved in warm water, and keeping up free action of the bowels.

September 24th.—Our patient is no better; there is more weakness or declension in power of voluntary muscles; no water passed; stomach exceedingly irritable; anorexia; no continuous refreshing sleep, but short disturbed dozing; twitchings about the face and arms; pulse 74; respirations 24; temperature of body 102° F; I introduced a large sized catheter, and drew off three ounces of dark coffee-looking fluid. To continue treatment.

September 25th. — Met consultant. We agree that there is no improvement; another medical gentlemen joins us; neither will agree to a diuretic for common scientific reasons. Treatment to be persevered with.

September 26th.—Patient anxious, restless, and drowsy; breath smells of urine; pulse slow; distension about abdomen; vomiting of dark green coloured fluid, with ammoniacal odour; burning pain over kidneys; bowels freely acted on; drew off about an ounce of blood from the bladder.

September 27th.—Incessant vomiting; inclination to sleep, but very restless. Thoracic complications first evinced; respirations noisy; inspiration prolonged, painful, and wheezy; expiration short, abrupt, and followed by evident relief; tongue dry and coated with white mucous looking fur; insatiate thirst; no urine passed; bowels well opened; no inclination to talk; to have iced champagne and nourishing soups.

September 28th.—Patient, much weaker, is now unable to sit up in the bed unsupported; pulse 70, weak, and jerking in character; respirations 20; temperature between thighs 102°; intellect still clear; pupils somewhat dilated and don't contract under the influence of light given by wax taper; tongue dry and streaked with yellow lines. Skin and breath emit a urinous or ammoniacal odour; no desire to make water; introduced catheter, and drew off a small quantity of bloody fluid, which separated afterwards, the blood subsiding to bottom of utensil leaving a straw-coloured fluid floating on the surface.

September 29th.—General muscular twitchings; very noisy and embarassed breathings, as if the bronchiæ were filled with phlegm, and no effort made to dislodge it by coughing; does not lie still a minute; refuses to permit the introduction of catheter; does not raise his eyes, but

appears stupid and drowsy ; has no pain in any situation ; thinks he will be better in a few days.

Evening Visit.—In and out of bed with help of nurse and relations all the day ; keeps being sick ; refuses nutriment and medicines ; has had a convulsive seizure ; surface of body moist and cold.

September 30th.—Gradually became more quiet, and appeared to die by coma.

Notwithstanding a most earnest appeal, no *post-mortem* examination would be permitted.

Case 2.—*Hæmaturia, ending in complete suppression.*—E. G., a woman of about fifty years, who had borne a large family, and had been out of health for some weeks, sought my advice one day in the house of a neighbour of hers (whose child I had been in attendance on) for violent pain across the small of the back, and difficulty in passing water, which occasionally contained blood. I prescribed some ordinary mixture for her, and then lost sight of the case, being so much benefited that she did not persevere. On the 12th of March of the present year I was requested to see her again, and, upon visiting her, I learned that for four days she had been passing blood, and that for two days preceding my visit there was complete suppression of urine. She complained of burning pains over the region of the kidneys, sickness, accompanied by vomiting, colicky pains in bowels, headache and thirst. The pulse was 72 ; respirations 24; and temperature of body in axilla 104° F. As there was inclination to costiveness, I purged her freely with a full dose of compound jalap powder, and gave her a mixture of the tincture of the perchloride of iron.

March 13th.—Relieved of colicky pain in bowels, but the distress across the kidneys she expressed as being unendurable. No urine eliminated. Constant nausea, anorexia ; spent a sleepless and disturbed night ; ordered a blister to be applied over both kidneys, and diluents to be freely taken.

March 14th.—This is the fourth day and still no urine has been passed—not even any attempt made. There is no water in the bladder. The bowels act freely, but the vomiting continues. The pulse is 70, respirations 22, and temperature of body decreasing, Ordered a warm bath.

Evening visit.—Woman no better ; anxious and restless, inclined to become drowsy; breathing laboured and wheezy, and the pulse slow and weak—the pulse of an unfilled artery. To continue treatment.

March 15th.—The breath smells of urine. I introduce a female catheter into bladder, but no urine flows ; the apertures are plugged with blood. The respirations are become more embarrassed, and the case seems hopeless. The woman must quickly die if not relieved. I prescribe full doses of acetate of potass, tincture of belladonna, small doses of digitalis, and infusion of broom.

Evening visit.—No urine, nor even a trace of it. The pain in the loins is past endurance. I rub an extract of belladonna, dissolved in glycerine, over the kidneys. Cover it with silk paper, and apply a bran poultice external to all. I give her small quantities of brandy and soda-water to relieve sickness, and administer a draught with cyanide of potassium, and advise the diuretic to be pushed. Anxious for the safety of my patient, I visit her again in four hours. I find she has experienced the sensation of requiring to make water, but cannot. I think I can detect some fluid in the bladder. I advise a warm hip-water directly, and perseverance with the remedies.

March 16th.—I find my patient has voided about one and a half ounces of bloody urine, but the pressing symptoms continue ; pulse is so feeble in action and in character that I omit the digitalis. Sickness continues, but no vomiting to signify. Has spent a restless night.

Four hours or so after, a relative calls upon me to say the woman has made a large quantity of water. Upon my arrival I find half-a-pint of urine, tinged with blood, in the urinary utensil, containing a thick sediment of lithates. Patient, accordingly, is more sanguine of living. To have brandy-water acidulated with bi-tartrate of potass for drinking, since the thirst continues ; to have an increased quantity of acetate of potass every two hours, and to repeat the hydragogue cathartic.

March 17th.—In the course of twelve hours, there has been passed fourteen ounces of thick, dark-coloured urine. I find it contains lithic acid in composition with soda, and that it is deposited in large quantities as the urine cools. Vomiting has abated ; pain across kidneys of a different character, dull and aching ; patient more hopeful ; breathing better, and pulse more full in character, though still slow in action. To continue diuretics, and have some draughts of sal volatile, egg and milk, and beef-tea *ad libitum*.

March 18th.—Urine passed freely, pain subsiding, and patient altogether in every respect improving.

From this time there was no relapse. I gave her ferruginous tonics, and in ten days had the pleasure of finding her down stairs. I examined this woman's urine frequently when convalescing, and was surprised at the quantity of urea which it contained. Following M. Becqueril's method of putting a little urine in a watch glass, and gradually adding a like quantity of nitric acid in such a way as that the acid might get underneath the urine to the bottom of the glass, I obtained the crystallized deposit of urea in three or four hours. I coincide with M. Becqueril that, when the quantity of urine is increased, the quantity of urea is increased. It was so in this case, for it is impossible the large quantity of urea obtained could possibly have accumulated in the system without more serious consequences.

Case 3.—*Supposed calculus impacted in right ureter, with atrophied kidney of opposite side producing suppression of urine.*—T. H., aged fifty-six years, of spare habit of body and delicate appearance, sought advice for violent pain commencing across right kidney, extending down right ureter, and reaching the testicle of same side, which was retracted. He had suffered in the past from renal disease, and his last attack lasted over a period of several weeks. Upon removing his clothing, I observed a marked depression, corresponding to region of kidney of left side, there was a marked fulness, and tenderness on the other side—the patient crying out when firm pressure with the fingers was made. He has only passed a very small quantity of urine during the past few days. He is weak, and anxious as to the result. The tongue is dry ; pulse 70, bowels costive ; appetite deficient. Prescribed a hydragogue purgative, a mixture of potass with belladonna, and a liniment of chloroform and belladonna for local application.

Thirty-six hours afterwards I was summoned to his house, as he had not passed any urine for eighteen hours. The last voided was bloody, and contained mucus. The pain is violent ; testicle well drawn up ; vomiting continuous and distressing. I order a warm bath, and return in five hours, but find no improvement in general symptoms. His present state now is as follows :—Nausea with vomiting ; vertigo ; burning pain across kidneys and along ureter ; restless ; frequent desire to make water, but unsuccessful because there is none in bladder ; uneasy sensation at end of penis ; pupils natural ; skin cool, temperature of body 108° F. ; pulse 70 ; respirations 18 per minute. I lose no further time, but exhibit full doses of acetate of potass, tincture of cantharides, tincture of digitalis, spirits of chloroform, and decoction of broom tops. I direct a warm hip-bath every four hours, the parts to be well rubbed with the embrocation, and steamed flannels applied afterwards. To have plenty of diluents—barley water and lemon kali *ad libitum*. I returned again in three hours ; he does not retain the medicine, so I mix him a prussic acid draught, and direct the diuretic mixture to be given in small quantities, and more frequently repeated. After eight hours treatment he experienced the sensation of some rough body passing lower down his ureter, which produced a hot burning pain, and set up violent vomiting. Three hours afterwards he passed bloody water, which gave ex-

cruciating pain—genuine *ardor urinæ*, which put him on his knees in bed. From this period he kept passing urine, which gradually cleared; but no calculus came away until the end of a week, when he was able to retain his water so as to fill the bladder; and, in the act of emptying it, a very small and irregular oxalate of lime calculus, which I believe is rare as a renel calculus, weighing only a few grains, came away in the gush of urine. The man soon became convalescent, and resumed his employment of a frame-work knitter.

I narrate the first case—which is pathognomic of anuria—because it shows the longest period a man can live without secreting and passing urine, and because it is just such a case, if allowed to follow the bent of my own inclination, wherein I would give a powerful diuretic, after a fair trial, and the failure of, the common remedies. The two other cases speak for themselves, the result of treatment is eminently satisfactory, and I feel assured, had I not given the diuretic, that both must have perished from uræmic poisoning. I must not be misunderstood—in idiopathic and single uncomplicated inflammation of the kidney I should not be foolish enough as to once think of a diuretic, no more than in congestion the sequence of the exanthemata; but I do believe in cases of congestion induced by mechanical obstruction, whether in the ureter or in tubular portion of kidney, leading on to suppression, that powerful diuretics should be employed before the patient sinks. In the district which I live we possess a lady practitioner, far and wide famed for her water cures. This I know, she has succeeded in forcing the water when eminent members of our profession have given up their patient's disease as hopeless and beyond their treatment, and, if I mistake not, infusion of digitalis is the drug she uses. I am no advocate for amateur doctors. I know her success, and I have experienced the folly of her trying to cure all affections by the same method of treatment. The subject needs discrimination, but is well worthy of future investigation by those to whom may fall the treatment of parallel cases as I now relate. If the anuria extends over the fifth day, we are bound, I hold, to exhaust our treatment. I do not consider that Prout was correct when he remarked that coma became established on the fifth day if the suppression was complete. My experience in the past extends such an event to the evening of the eighth or morning of the ninth day, because I consider some of the urea is decomposed and converted into carbonate of ammonia, a phenomenon first remarked by Schmidt in the suppression of urine in *cholera morbus*.

ON A CHANGE IN THE URINE FROM THE EXTERNAL USE OF CARBOLIC ACID.*

By Augustus Almen.

In a former part of this journal, page 105, Mr. Waldenström has given an account of an altered appearance of the urine, &c., observed in some patients at the Academical Hospital, who were using a solution of carbolic acid in oil, either in dressing, or as an injection into abscesses, and he called particular attention to the danger of the occurrence of nephritis, and to the necessity for examining the urine during the employment of carbolic acid.

Although I have only a few very unimportant observations to make, which should most fitly be taken in common with the paper just referred to, yet, considering the practical importance of the inquiry, and the extremely unusual appearance the urine presented, I will say a few words on the method of determining the presence of carbolic acid in the urine.

The urine of various patients admitted to the hospital, had, after the use of the acid in question, a very dark, almost black, tarlike, appearance. It was acid in re-action, turbid, and did not throw down any unusual deposit. The urine contained albumen, but not in any great or extraordinary quantity, in fact, only to an insignificant amount. Blood could not be detected,* and the urine did not present anything unusual except its black tar-like colour, and a peculiar smell. When no absolutely certain re-action of carbolic acid could be obtained, either with the urine itself or with the residuum after the ether, with which the strongly acidulated urine had been agitated, though the presence of carbolic acid was highly probable from the smell of the fluid, about 400 cubic centimetres (some 14 ounces) of the urine was strongly acidulated with sulphuric acid, and about a third part was distilled from an ordinary retort, with glass condensing tubes. The distillate was as clear as water, colourless, smelt strongly of carbolic acid, and gave beautiful and undoubted re-actions of the same. For comparison, an analysis was instituted at the same time with distilled water, in which some drops of carbolic acid had been dissolved by agitation.

The distillate and the aqueous solution of carbolic acid, when mixed with some ammonia, and, subsequently, chlorinated lime, assumed the same pronounced and beautiful blue colour. Very thin chips of fir-wood (spruce fir), thoroughly soaked in the two liquids, and afterwards dipped into dilute-hydrochloric acid, and exposed to the sunlight, became with both mixtures beautifully blue, especially at their thinnest edges. The distillate, agitated with ether, and the clear ether evaporated in a watch-glass, left as a residuum oil-drops, smelling strong of carbolic acid, which, when mixed with water, and also when treated in other ways, for example, with strong nitric acid, behaved like carbolic acid; although on treating them with concentrated sulphuric acid, then neutralising with chalk and filtering, I was not fortunate enough to obtain with perchloride of iron the beautiful violet colour which is, without difficulty, got in the case of pure carbolic acid.

No doubt as to the presence of carbolic acid in this urine remained, and that its amount was not trifling, I conclude from the fact that the small quantity of urine which was subjected to distillation, afforded a distillate of which a small part, agitated with ether, left a not inconsiderable oily residuum. Although I have not instituted any comparative experiments with normal urine, I yet take it for granted that it does not contain carbolic acid in any such quantity as was the case in the present instance.

The unusual tar-like appearance of the urine naturally cannot depend on the presence in it of carbolic acid, and as urine so affected is not observed during the internal use of this substance, Mr. Waldenström's presumption, that it results from the presence of oxidised products of carbolic acid, formed even before the absorption of the acid, seems a very probable one. As is well known, carbolic acid and creosote have a great tendency to change; even when kept in well-closed glass bottles they become tinged with a more or less reddish-brown colour, and carbolic acid dis-

* Translated from the "Upsala Läkareförenings Förhandlingar" (Vol. v., Part III, page 253), by J. W. Moore, M.B., Ch.M. Dub., L.K.Q.C.P. Ex. Schol. T.C.D.

* The most delicate, simplest, best, and a really practical test of the presence of blood in the urine, is that mentioned by me at the meeting of Naturalists in Stockholm, 1863 ("Proceedings of the Meeting, Stockholm, 1865," P. 481), viz., the guaiacum test, which is most readily carried out in the following way:—Tincture of guaiacum (a solution in spirit of guaiac resin), and ordinary turpentine in about equal parts, or from half to one cubic centimetre of each, are blended into an emulsion in a test-tube, after which, a small quantity of urine is added in such a way as to sink to the bottom in a separate layer. Whether the urine is normal or unhealthy, for example, containing albumen, but not blood, the emulsion undergoes no change until a rather long interval, but if the least blood is present in the urine, or if a drop of blood be added to it, the emulsion immediately on mixing with the urine becomes of a light-blue colour, then darker, and finally the blue resembles a solution of indigo or Prussian blue, these changes varying in rapidity and intensity, according to the quantity of blood present. Many years' employment of this simple test has convinced me of not only its incredible delicacy, but also its reliability. Neither normal nor ordinary albuminous urine, if free from blood, changes the guaiaco-turpentine emulsion at all in such a way that any doubt or uncertainty can arise as to whether blood is present or not; and this test for blood is for clinical purposes (not for medico-legal) simpler and far better than all others. How Teichman's blood-crystals may be obtained from urine and other fluids containing blood is mentioned in the same Proceedings, at page 482.

solved in water when treated with chromic acid (or whit- $K O_2 Cr O_3 + S O_3$) turns to a dark brown, not unlike the urine under discussion. It seems not improbable that the carbolic acid mixed with blood and pus should, on exposure to the air, and, perhaps, through the properties possessed by the blood of ozonifying and promoting acidulation, might undergo a rapid and energetic acidulation with the formation of the dark products of oxidation, which, afterwards, along with the unaltered carbolic acid, are absorbed, and pass off in the urine. At an hospital an experiment could easily be instituted as to whether a little carbolic acid, mixed with similar pus, and agitated with exposure to the air, after some time assumes a dark, tar-like appearance. That the dark colour is not developed after the water is passed, or while it is in the bladder, seems to me likely, from the fact that, if the urine is agitated with a little carbolic acid, and exposed, without shelter, to the air, neither its re-action nor its appearance is changed (it does not putrefy), and a smaller quantity of urine evaporates even without undergoing any noticeable alterations.

Sharing Mr. Waldenström's view, that a dangerous nephritis might possibly arise from the external use of carbolic acid, I yet do not believe that we should therefore abstain from a judicious employment of it. The acid in question possesses, as is well known, unusual antiseptic properties, even when used in extremely minute quantity, and therefore I cannot imagine any advantage that is likely to accrue from employing it in so large an amount, and in such concentrated solutions as physicians appear to prefer. In my opinion its good effect depends less on the quantity of the acid than on a complete and general contact with the pus, and, doubtless, quite as good results might be obtained with much less acid. On the dressing a more dilute solution in oil should be the best, but for injection an aqueous solution appears to me to be the more serviceable, if it is brought into contact with the interior of abscesses, an end which is most readily attained by an injection of a large quantity of an aqueous solution of carbolic acid, which should subsequently be rinsed or squeezed out. Experiments with this solution, or even better with a solution in spirit, of which various quantities, according to various cases, may be added to the water used in washing, and to an injection fluid, would be of advantage.

From what is already known of the action of carbolic acid on the kidneys, it is then always our duty not to omit an examination of the urine for albumen, during even the external use of this substance, and this, too, even if the urine does not present any abnormal appearance.

Hospital Reports.

ROYAL FREE HOSPITAL.

THERE is a manifest improvement in many respects in the arrangements of this excellent institution. The wards look bright and cheery. They are kept scrupulously clean, and the nursing department is beyond all praise of ours, in comparison with what it formerly was. On visiting the hospital the other day we were shown many most interesting cases under the care of Mr. John Hill. The first object of interest presented to us was a coloured drawing of the urethra, ureters, and kidneys of a patient, who had died some week or two after the performance of the operation invented by Mr. Holt for splitting the strictures. He caught some kind of fever which proved fatal. The drawing showed that the urethra had been left intact by the splitting process, which had simply burst the submucous tissue. Mr. Hill showed us a case of stricture of the urethra in which he had performed Syme's operation. This operation he finds only necessary in four per cent, or so, of all cases of stricture. There was felt extensive, thickening of all the tissues in the neighbourhood of the strictures. Syme's operation, says Mr. Hill, is one of the most difficult operations in surgery. In the absence of M. De Meric, who, we regretted much to hear, was suffering from bronchitis, Mr. Hill had to attend to one of that gentleman's cases, where excision of the shoulder joint had been performed on account of an extensive burn, caused by the patient, a man of some thirty-six years of age, falling on a fire, whilst in a fit of epilepsy. There is a most successful operation for remedying the effects of the contraction caused by burning in the same ward under Mr. Hill's care, in which the boy has been subjected to all kinds of operations in other hospitals ; but at length has been enabled to shut his mouth pretty well, by means of the excision of two V-shaped pieces from the lower jaw, and by using an instrument to keep up the head whilst some new incisions made in the sub-clavicular spaces were granulating. In another ward, we observed a case of Pirigoff's operation, a disarticulation of the shoulder joint, and a patient who had broken his tibia after having had his knee joint excised some few months back. A prize fighter had his jaw broken professionally by the blow from a brother of the P.R., and next bed to him was a patient suffering from stricture of the gullet caused by swallowing sulphuric acid. This poor fellow had been in the habit of himself passing a probang down the œsophagus into the stomach in order to relieve him from his inability to swallow. Recently, Mr. Hill had nearly had recourse to œsophagotomy in this case. In the female ward we noticed a case of tertiary syphilitic cachexia, following after a syphilitic phagedænic ulceration of the rectum. We understood that the venereal wards are still in disuse, and we are inclined to suspect that the able operative surgeons of the hospital are rather glad that this is the case, as they have thereby more beds for surgery. To this we have no objection ; only we would remark, that in the year when investigations were made as to the hospital accommodation for syphilitic cases, the Royal Free Hospital was greatly complimented for its charitable and tolerant practice of giving shelter to so many unfortunate women, who had been turned away from other less humane hospitals. We trust that the mantle of Dr. Marston will fall on some of his successors, and that they may remember that human misery and disease are very prevalent among prostitutes, and that there are as yet too few beds in London for them to allow of all the beds in the Royal Free Hospital being turned into more *respectable beds.* We have said enough, we think, to show what an excellent field for surgery the hospital is at present, and those who are well acquainted with the skill of Mr. Hill and his *confrères* may grant with us that no better opportunity for learning the operative art exists in London. Ladies wishing to learn nursing, too, or even the art of surgery, could not do better than become nurses in the hospital under the care of Miss Cole. If they filled precisely the same situations as the young nurses, we remarked in passing through the wards with Mr. Hill, they could not fail to learn much of practical surgery, and of surgical nursery. It has always seemed to us a pity that the Royal Free Hospital wards were not used for clinical purposes. At least, we have seen in them far more surgical cases than usually occurs in much larger hospitals. The well-known unequalled attention and skill of one of the younger surgeons of this hospital are quite sufficient to account for this fact, and we can only add that students would do well to become dressers for a time in wards where they will have ample opportunities of study, conjoined with tranquility, and absence of those distractions which exist at so many of the large school hospitals.

METROPOLITAN FREE HOSPITAL.

AMONG the out-patients of Dr. James Jones, we observed a case of fluctuating tumour of the liver in a young man, aged twenty. Dr. Jones considered this as probably a case

of hydatid cysts, and treated the patient by painting the tumour over with strong iodine paint. He is persuaded that the human tissues are more permeable than is generally supposed, and that enough iodine passes through the integuments into the cyst in many such cases to destroy the vitality of the hydatid, As a general rule, Dr. Jones is not in favour of operating in cases of presumed hydatids of the liver, unless where suppuration has manifestly taken place. In many cases the hydatids perish spontaneously, and become absorbed. He has never seen a death occur from leaving such tumours to nature, although he is aware that many such fatal results have been reported.

(Under the care of Dr. C. R. DRYSDALE.)

Chloral Hydrate in Pertussis.

JOSEPH HILBERT, four years, has had pertussis for two months, and been very ill indeed. Coughed as much as thirty to forty times in night, and "was often nearly suffocated." Brought up blood with cough. During daytime had very severe attacks "every half hour," and sometimes brought up blood.

September 6th, 1870.—Seen by Dr. C. R. Drysdale, who prescribed hydrate of chloral, gr.j., syrupi simplicis, ʒj., to be given frequently; but not more than ten times in twenty-four hours.

September 13th.—Mother says this medicine has nearly stopped the cough. He hardly whoops at all now, and does not bring up blood. He had been given many medicines before this with not the slightest effect. Among others, bromide of potassium had been prescribed by another medical man in five grain doses. Dr. Drysdale is much pleased with the action of chloral hydrate in this complaint.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE LANCASHIRE ALKALI TRADE.

MR. GOSSAGE read a paper upon the above subject, which was of considerable importance, although only from a technical point of view. Mr. Gossage may be viewed as the originator of this trade in that district.

As one of the most important facts connected with the soda manufacture, I must not omit to notice the passing of a legislative measure, entitled "The Alkali Act, 1863," rendering it imperative that all manufacturers decomposing common salt, for the production of sulphate of soda, should condense not less than 95 per cent. of the hydrochloric acid gas evolved by such decomposition. In my former paper I described fully the means which I had devised and carried into successful operation in the year 1836 for effecting such condensation, and these means are now adopted universally by the soda manufacturers, and so successfully that not only do they comply with the legislative requirements of condensing 95 per cent. of the hydrochloric acid set free, but in many instances this condensation exceeds 99 per cent. It has been very fortunate for the manufacturers as well as for the public that Dr. R. Angus Smith was selected by the Government to undertake the duties of chief inspector under the Alkali Act of 1863. This gentleman, with his able staff of district inspectors, has assisted greatly in promoting the effective working of the system of condensation. The able reports submitted annually to the two Houses of Parliament by Dr. Smith contain the fullest details of the working of this legislative enactment, and it may be fairly expected that when the same amount of care and attention has been applied to subduing the bad effects resulting from other noxious vapours chemical manufactories will be relieved from the charge of occasioning injury to their vicinities.

The most important use for hydrochloric acid obtained by such condensation is the manufacture of hypochlorate of lime, or bleaching powder, the demand for which has taken an extraordinary development since the introduction of straw, esparto grass, and some other substances than rags for the manufacture of paper.

At the date of my last paper, the chlorine required for the manufacture of bleaching powder was obtained by the action of hydrochloric acid on native peroxide of manganese. Recently, Mr. Walter Weldon, of London, after long-continued devotion of time, labour, and money, has succeeded in perfecting a process by which peroxide of manganese is obtained from the chloride of manganese, produced by the action of hydrochloric acid on peroxide of manganese. Mr. Weldon effects this object by causing the chloride of manganese to be decomposed by hydrate of lime, thus producing hydrated protoxide of manganese, which he converts into peroxide of manganese by causing streams of atmospherical air to be forced through the fluid mixture of protoxide and water. When in this state of minute division the protoxide of manganese absorbs oxygen from the atmospheric air and becomes converted into peroxide. Mr. Weldon has found it essential, for successful working, that not only a sufficient proportion of lime be used to precipitate the oxide of manganese, but that such an excess be employed as will be sufficient to form a chemical compound with the peroxide of manganese as this is produced, which compound Mr. Weldon designates as manganite of calcium. This process has been successfully carried into practice in this district, also in that of Newcastle, and it has already been adopted by some of the largest manufacturers of bleaching powder in both these localities.

It is well known that to obtain one equivalent of chlorine by the reaction of hydrochloric acid on peroxide of manganese, it is essential that two equivalents of hydrochloric acid should be employed, one of these yielding chlorine, the other chloride of manganese.

Mr. Deacon's process for the manufacture of chlorine without the use of manganese is one by which the whole of the hydrochloric is decomposed into chlorine. By this process each equivalent of hydrochloric acid yields an equivalent of chlorine.

Mr. James Hargreaves, of Widnes, has also devised means for producing chlorine without the use of oxide of manganese. He has a process for the separation of phosphorus from the iron-slag produced in the puddling operation of the iron manufacture. In carrying out this process the iron-slag is treated with hydrochloric acid, and thereby proto-chloride of iron in solution is obtained as a bye product, which is evaporated to dryness, producing dry proto-chloride, and this, by slow application of heat with access of atmospheric air, becomes per-chloride, which undergoes decomposition, yielding chlorine and per-oxide of iron. This process also yields an equivalent of chlorine for each equivalent of hydrochloric acid employed.

In my former paper on the soda manufacture, I took occasion to remark that nearly all the sulphur used in this manufacture (the cost of which is about equal to two-fifths of the total cost of materials required) was re-obtained in combination with calcium, forming what is expressly designated as "alkali water."

I noticed, also, that this presented a problem worthy the attention of my juniors for its solution. Dr. Ludwig Mond a German chemist, has made the nearest approximation to the solution of this problem with which I am at present acquainted. Mr. Mond's process consists, in the first instance in causing atmospheric air to be brought into intimate contact with the alkali waste, as this is left in the lixiviating vats after treatment with water. This is effected by the use of a ventilating fan, which forces air into the lower part of the vat under a false bottom. The air percolates the mass of waste and a portion of its oxygen becomes absorbed by the sulphide of calcium yielding soluble hyposulphate of calcium, and at the same time a portion of the sulphide of calcium becomes converted into soluble polysulphide of calcium. The oxidisation is so regulated, as regards its extent, that the resulting solution, when this is obtained and treated with hydrochloric acid, should yield sulphide of hydrogen and sulphurous acid in such proportions as to mutually decompose each other yielding free sulphur at the same time that the second equivalent of sulphur contained in the hyposulphurous acid of the hyposulphate of lime is set free. A very pure sulphur, almost absolutely free from arsenic, is obtained by this mode of working.

This process has been carried out successfully by various manufacturers, but, unfortunately, the quantity of sulphur obtained is far short of that contained in the waste, and I consider the problem I have mentioned still remains as an exercise for ingenuity and perseverance.

In my former paper on the soda manufacture, I gave some particulars of the means I had adopted for obtaining copper and silver from the burned residua of copper pyrites which had been used for yielding sulphur to manufacture sulphuric acid. This mode of working has been superseded by a process devised and carried out by Mr. Henderson. This process consists in mixing a small proportion of salt with burned pyrites, previously ground to a fine powder, and exposing the mixture to a red heat, either in open reverberatory or closed furnaces, through which a current of atmospheric air is allowed to pass. By these means the small portion of sulphur which has escaped being consumed in the burned pyrites becomes oxidised, producing sulphate of iron, which decomposes common salt, yielding chloride of copper and sulphate of soda, which are obtained in solution on lixiviating the product with water. The copper is then precipitated from the solution by means of iron, and is obtained in the metallic state. A large quantity of oxide of iron is obtained as a residiuum from the lexiviation. This is sold to the ironsmelters for the production of iron. These operations are carried out very extensively by the Tharsis Metal Company, at Glasgow, Newcastle, and Widnes. There are also several other establishments engaged in the same business in the neighbourhood of Widnes—amongst others that of the Widnes Metal Company, where Mr. J. A. Phillips has carried out successfully a process invented by Mr. Santler, of London, for extracting gold, silver, and lead from the burned residua of copper pyrites.

In the year 1861, during the negotiations of the French treaty of commerce, it was estimated that the total quantity of salt decomposed in Great Britain for the production of soda was 260,000 tons. Of this quantity, 125,000 tons were decomposed in what is called the Newcastle district, and 135,000 in the Lancashire district. According to the returns of the Alkali Manufacturers' Association for the year 1869, the total quantity of salt decomposed for the manufacture of soda was 326,000 tons, thus showing an increase of 66,000 tons, or 25 per cent. on the total. Of this quantity, the decomposition in the Newcastle district, in 1869, was 142,000 tons, which, being compared with 125,000 tons in 1861, shows an increase of 17,000 tons, or 13·6 per cent. The decomposition in the Lancashire district is returned as 184,000 tons in 1869, against 135,000 tons in 1861, showing an increase of 49,000 tons, or 36 per cent. It would thus appear that the total quantity of salt decomposed for the manufacture of soda in the Lancashire district in 1869 exceeds by 30 per cent. the total quantity decomposed in the Newcastle district during the same year.

One of the most important applications of soda to other manufactures is that of the producton of soap, and it may be interesting to notice the increase in the production of this article, which is so essential to cleanliness, and, therefore, to civilisation. In the year 1852, when the excise duty on soap was finally abolished, the total production of soap in Great Britain was equal to 1,600 tons per week, less than one-half of which was produced in the Lancashire district. From some inquiries which I have recently made I am satisfied that the present production of soap in the Lancashire district is fully equal to the total production in 1852. We may, therefore, infer that the production of this article has doubled during the past eighteen years.

THE SOCIAL SCIENCE CONGRESS FOR 1870.

Mr. Phillips Bevan, F.R.G.S., read a paper on

LEGISLATION TO PREVENT ADULTERATION OF FOOD AND DRINK.

Although it is one of our most important social questions, the apathy and ignorance of the public on the subject of adulteration is astonishing. As each person thinks that all others are mortal except himself, so he imagines that adulteration affects any class but his own; and although we acknowledge its prevalence, and cry shame when we read of any particularly bad case, the sensation is but momentary, and we go on our way as before. What is adulteration, and what does it mean? It means the lowering of the physique of the nation, the poisoning of the people, the deterioration of our constitution; and, morally, a fraud practised by the seller on the buyer, a cheating, to which we have become so callous, that it has hardened our conscience for honesty in other and bigger things. The great difficulty in dealing with it is, that the Government is so slow to move; and even men in high places practically defend it, by declaring that it is not so bad as it might be; that the buyer must look to himself, and so on. It is also very common argument that people bring adulteration on themselves by buying such very cheap articles; so cheap, that they cannot be good for the money. But they do so in ignorance; and if the seller was compelled to label his goods with the names of the real ingredients, such as "best butter mixed with starch, mashed potatoes, and horse-bone oil;" "coffee, with bread-crumbs and sand;" "tea, with iron-filings;" "sugar, with chromate of lead;" "beer, with salt and cocculus indicus," it is not the least likely that their cheapness would tempt the buyer; and, if a certainty of detection and punishment followed, we should find that the sellers would think twice before they offered such articles. It is strange that, in all our sanitary machinery, the food question and its purity have been so overlooked; but pure food is as necessary as pure air, good drainage, or wholesome water; and it ought not to be left to the philanthropist to remedy the evil, with the tolerable certainty that he will only get snubbed for his pains. It is a Government question, as important as that of education or the Irish Church; and it ought not to be the duty of a private member of the House of Commons to bring in a Bill.

With a view to arouse public interest, in conjunction with Messrs. J. M. Johnson and Sons, of Castle street, Holborn, in February last, I established the *Food Journal*, feeling that there was a great want of some public organ to discuss these matters; and so convinced was I that no Bill could properly be passed without the knowledge of the legislation which prevailed in other countries, that the late Earl of Clarendon was applied to for permission to address the various British Legations and Consulates abroad on the subject. His Lordship not only gave that permission, but evinced his great interest in the matter by requesting that a circular should be drawn up, embodying all the enquiries on food matters that it was desired to make. A thousand of these were accordingly issued through the Foreign Office; and Earl Granville, who has taken up the subject in the same warm and earnest spirit as evinced by his predecessor, has forwarded for publication in the *Food Journal* a mass of valuable information, which has never before reached this country. To detail even an epitome of these answers, would take up far too much of the time of this meeting. I will, therefore, only briefly touch on some of the main points of the first question of the Circular—viz., "What legislative enactments at present exist in the country to which you are accredited respecting the adulteration of food and drink? Are these laws actively enforced; and how far do they appear to meet the evil?" "Very valuable information come to us from the United States, in Mr. Thornton's report; which adverts to the difficulty of getting systematic information, even through the well-arranged machinery of official correspondence. The *State* legislation varies very much in the different states, some possessing no legislation at all, and others inflicting very severe penalties. Each state legislates independently; and, in so doing, often delegates the regulation of these matters to the various town or county authorities within their borders. As a general rule, the adulteration of alcoholic liquors is almost universal.

In Rhode Island, the penalty for adulteration of food, drink and drugs, or for selling unwholesome food, is imprisonment up to six months, or a fine up to 200 dollars.

In Vermont, for adulteration of medicine, imprisonment up to two years, or a fine up to 400 dollars. For selling adulterated intoxicating liquors, from 10 to 300 dollars for each offence. For selling unwholesome provisions, imprisonment up to six months, or fine up to 300 dollars. For adulterating bread or any food with impurities injurious to health, imprisonment up to two years, or fine up to 300 dollars.

In Ohio, for adulterating spirituous liquors a fine of 100 to 500 dollars, *and* imprisonment for ten to thirty days.

In Indiana, for adulterating any food or drink, a fine of from 50 to 500 dollars, and, at discretion of the court, imprisonment up to three months.

In Illinois, a fine up to 100 dollars, or imprisonment up to three months.

In Missouri it is a *misdemeanour*, punishable with imprisonment up to one year, or a fine up to 500 dollars; but adulteration of intoxicating liquors with strychnine or any other injurious substance is a *felony*, punishable by imprisonment from two to five years. Every liquor seller has to appear before the county clerk, and enter into a bond of 500 dollars, with good security, not to mix or adulterate his liquors with any material, not even water; the penalty for non-compliance is a fine from 50 to 500 dollars. There is also a very rigorous inspection and testing of all spirituous liquors imported into this state.

In Mississippi adulteration is punishable by an imprisonment from one year to five years.

Cincinnati appears to turn its attention more to milk, for the sale of which the rules are extremely strict. Each milk seller has, under a penalty of one-hundred dollars, to have his milk inspected and tested, that it should not be watered, or the produce of diseased cows, or of cows kept in stables and fed upon garbage. The address of the dairy, whence the milk came, must be legibly painted on each stall.

In Georgia every baker, brewer, distiller, grocer, merchant or other person selling pernicious or adulterated food and drink, and also all accessories after the fact, are liable to a fine up to 1,000 dollars, imprisonment up to six months, whipping up to thirty-nine lashes, and to work in a chain-gang up to twelve months.

In Texas the fine for adulteration is from 20 to 500 dollars.

These laws generally work well throughout the states, but all the reports show that there is generally a pretty high standard of reputation amongst the dealers, although it is at the same time true that the system of comprehensive laws, and the knowledge that they will be strictly enforced, tends to preserve this feeling.

The Prussian Penal Code provides that any person selling adulterated or spoiled goods shall be liable to a penalty up to fifty dollars, or imprisonment for six weeks, with confiscation of goods. In these cases, it is not necessary that the seller be aware of the adulteration, for he is liable just the same. If death ensue, the seller is punished with death; but if only severe bodily injury, the penalty is imprisonment from ten up to twenty years. At Konigsburg there is an additional law respecting the sale of damaged meat, and particularly of pork containing *trichinæ*. At Leipzig the same regulations are in force, but the police are not active. At Hamburg, if any injury happens to the buyer, the seller is liable to be imprisoned for from three months to four years.

In Holland the Dutch law is very similar to the Code Napoleon, and inflicts a punishment of imprisonment for from six days to two years, with a fine of from 16 to 500 francs. The adulteration of bread with copperas or vitriol is dealt with by an imprisonment of from two to five years, and a fine of from 200 to 500 florins. Not only is punishment provided for people who mix ingredients for adulteration, but also for those who manufacture or sell the ingredients, knowing that they were to be used for adulteration.

Any fresh legislation on this subject should be compulsory in its character, and not permissive. All articles of consumption which are manufactured should have their ingredients declared, for there is a feeling prevalent amongst manufactures, as for instance, cocoa makers, that as long as their articles contain nothing hurtful, they are at liberty to call them by the general name of cocoa. Still, a sophistication is to a certain extent a fraud, and every purchaser has a right to know what he is purchasing; and although we might be safe in the hands of the largest and most respectable manufacturers, there is a considerable class of unprincipled makers who are not above taking advantage. Differences of opinion sometimes occur as to the relative hurtfulness of certain common adulterants; and an eminent authority has assured me that he had grave doubts as to whether alum was not a good thing instead of a bad one. I would suggest that there should be a Food Sub-department formed, which should take cognisance of all food legislation and supplies. To it a board of two or three of the most eminent analytical chemists should be attached, who should examine and pronounce upon all disputed chemical questions, and whose opinion should be law. The sub-department should have the election of, and a certain amount of control over, the county and borough analysts, whose appointment should be compulsory and not permissive; neither should it rest with vestries or corporations, many of the members of which are often largely concerned in adulteration. Inspectors should have power to visit and take samples from all dealers in articles of food, subject to certain checks, so as to prevent any risk of tyrannical domiciliary visits. They should also have the power of testing the supplies furnished to public bodies, such as union contracts; for guardians have frequently a habit of accepting tenders for food at a price at which the real article cannot possibly be supplied; as a London Union Board did the other day in the case of butter. In cases where a petty dealer declares his ignorance that the goods which he sells are adulterated, I should make the onus of proving this fall upon him, and then it would be for the Food Sub-department to take the matter up, and prosecute the manufacturer. When adulteration takes place before importation, as in the case of the Maloo tea mixture, the department might well provide the machinery for setting consular and other influence to work to prevent it; and might also step in as the proper arbiter between conflicting interests. In this very case, a great fraud on the public was allowed to go unpunished, because the Customs could not legally forego the duty.

As to offences, when proved, I am no believer in either a very small or a very large fine; but I would have no sliding scale at the option of the magistrate. For the first offence the penalty should be sufficient to make the offender smart in his pocket; for the second, I would double it, and have an *affiche* detailing the offence put outside his door, as also outside the door of the church, police-station, and town-hall, for a month. The case should also be advertised in the local papers at the offender's expense. For the third offence there should be imprisonmebt for one month, with hard labour. Adulteration is either a fraud, or it is not, and it should be punished like any other cheating.

Abstracts of Lectures.

SESSION 1870-71.

QUEEN'S COLLEGE, BIRMINGHAM.

After a word in favour of the provincial schools, Professor Berry, F.R.C.S. said:—As far as medicine was concerned they had a right to demand that the General Medical Council should be properly constituted, that the various grades of our profession should be truly represented, that the education in the three kingdoms should be more uniform, and that the members of the profession should have perfect freedom to practise untrammeled by mediæval privileges. He directed attention to the fact that while practical science had been making, during the present century, great and rapid advances, medicine had not been behindhand, but had achieved results as striking, and advanced with strides as rapid, as in any one department of science. He then went on to show the progress that various departments of science had made during the present century, and having said much of surgery, turned to medicine in which the advance, he thought had been as remarkable. The physician had acquired a far more extended knowledge than his predecessor of the last generation had of the nature and diagnosis of the various diseases to which the body is liable. In proportion as his knowledge had been precise and clear, so also had he been able to use his remedial means with greater precision for the relief and removal of them. They had also learnt to know more precisely when they ought to strike into aid nature with the resources of art, and when they ought to leave nature to her own unassisted efforts. Every step of true progress in this knowledge formed, undoubtedly, a step of trne advancement in practical as well as scientific medicine. As evidence of how much practical medicine had progressed, he adverted to many improvements in the practice of medicine in relation to particular diseases, as scurvy, now banished from our fleets; the improved treatment and detection of the oxalic, phosphatic, and other diatheses, indicated by the state of the urine; to our increased knowledge of the diseases of the head, chest, abdomen, and pelvis; and to the vast addition made latterly to our previous knowledge of the importance of various prophylactic and hygienic resources in the prevention of disease.

QUEEN'S HOSPITAL, BIRMINGHAM.

The Introductory Address was delivered by Dr. Fleming, who devoted much of his address to the science and art of healing. The art consists, he said, of a series of rules of action directing how to cure or prevent the disease which the science has enabled us to understand. There are many arts, however, which may be practised with success where the sciences on which they are founded are unknown to the practitioner; take photography and telegraphy as examples. The student may therefore ask, Why should he spend so much time in studying the science of medicine in order to practise the art? When the science on which the art is founded is perfect, the rules which form that art are certain, and admit of universal application; and the more nearly the science approaches perfection, the fewer exceptions do we find to the rules in the arts dependent on it. At present the science of medicine consists of a number of groups of biological facts, often unconnected by any known fundamental law; it is, in fact, an imperfect science. And though in the greater number of cases certain effects follow certain remedies, there are always sufficient exceptions to remind us that we have to deal with vital phenomena of a very complex and uncertain nature, and which oblige us to fall back on the science from which our art springs. Were the public made more cognisant of this fact, it would put a stop to a great amount of evil, and amateur doctoring would be looked upon as too dangerous, even for the most adventurous. "Infallible cures" and "universal remedies" would then meet with the contempt they deserve.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

The Address was delivered by Dr. T. C. Nesham, who urged the necessity of devoting the first two or three years of their studentship to the study of human anatomy, physiology, and chemistry.

Having shown how these are to be learned practically, he said that at the end of two or three years they would pass on with a sound basis of preliminary education to the study of morbid action—to the science of the practice of medicine. And where were they to learn this? A little in the lecture-room, a little more in their study at home, but most of all at the bedside of the patient, where they would see morbid action in all its different phases of development, trace its course from day to day, and mark the result of efforts made to alleviate and cure. In the study of medicine they might avail themselves of either the inductive or deductive methods of reasoning; but whichever they employed they must be sure to verify every step of the argument by practical experience, or else the complete theory would be a source of danger, and the propositions they had deduced would be found in practice to be erroneous. He desired them to remember that, more than 2,000 years ago, Hippocrates had recognised the fact that nature when attacked by disease had a tendency under certain conditions to restore herself to health. If they wished to be successful practitioners they must remember this power, the "vis medicatrix naturæ." It was one great secret of the advance of our knowledge that we used as far as possible, in the study of medicine, scientific argument and logical sequence, but at the same time qualified and regulated them by practical experience, and thus endeavoured to establish the agreement of "theory with practice, and of reason with experience."

In urging the advantage of pathology the lecturer proceeded:—"The post-mortem room must be as familiar to you as the walls of the hospital. I would have you enter it with feelings of reverence and awe, with your minds earnestly bent on scientific investigation. You go there to rifle the dead of their secrets, for the benefit of the living, and not to gratify inquisitiveness or idle curiosity. Much that was dark and obscure will be revealed, the cloud of uncertainty which hung over many perils will be rolled away, and perhaps some errors of diagnosis detected. Pathology is as yet only in its infancy, and I look to improvements here as one great source of the future advance of medical science."

LEEDS SCHOOL OF MEDICINE.

The Address was delivered by Mr. E. Atkinson, the lecturer on botany, who dwelt first upon the importance of established principles of conduct, and next upon the value of an orderly and methodical disposition of time to the student. "Before presenting yourselves here for the commencement of special professional studies, you have all, as in duty bound, submitted to one or another of those very moderate previous examinations in arts (as they are rather magniloquently styled) which the authorities require. But let me hope that the measure of knowledge exacted from you on that occasion is no true guage of your acquirements. Indeed, it is difficult to imagine what art is illustrated by this elementary process, except it be the art of legerdemain, in converting a very ordinary schoolboy into a certificated student. Greek, for example, is an optional subject, while half the technical terms employed in medicine and the allied sciences are derived from this language; and how, then, are we to expect you to understand words which will meet you at every turn unless you have some previous knowledge of it. Mathematics, again, are required to so small an extent that, unless you have proved yourselves more than a master for your examiners, it may be doubted whether the main object of this branch of science—viz., the acquisition of a habit of close reasoning—has been attained; while the rudiments of chemistry and the natural sciences are left out of the field altogether. The authorities have, doubtless, done well to require satisfaction as to the previous knowledge of candidates for medical education by instituting these examinations; but have they gone far enough? Our daily experience says they have not. The four years usually allowed to special professional study are not any too long for the purpose." Mr. Atkinson thought the student, therefore, ought to come to a medical school thoroughly grounded in all preliminary knowledge, and he urged that botany and some knowledge of chemistry, with zoology, should be considered necessary parts of a liberal general education.

MEDICAL POLITICS AND THE INTRODUCTORIES.

We have given so fair an account of the several Inaugural Addresses that our readers may think sufficient space has now been accorded to them. Before, however, it is too late, we desire to draw attention to the hopeful sign that more than one lecturer ventured to mention questions of medical politics. There are, unfortunately, those among us who exhibit indifference to such points, but their apathy is the result either of ignorance or of too narrow a view of what is comprised under the term. Medical politicians, we know, do not make money, but a good number of them give their time and zeal to elevate the position of their brethren; and they include in the

term medical politics, everything relating to the general welfare of the Profession as a body. Education is, then, one of their fundamental questions, and these introductory addresses could not but be full of interest to them.

The regulations of the various examining boards, the means at our disposal to meet them, the condition of our schools, the changes that have been made, the improvements contemplated—all these and many other points deserve fuller attention than they have yet had, and must give rise to much discussion.

Mr. Hancock gave a series of figures relating to the preliminary examinations at the College of Surgeons, that he did not hesitate to call "disastrous," and which clearly shows how little prepared to study medicine are many who aspire to practise it. It can hardly be said that this college has pitched its standard too high, and yet we have distinct proof that it was much higher than the general public supposed. Is that one reason why the public valued the Profession so little? One of the liberal professions should comprise only men of a moderate education like that shadowed forth. This revelation, however, at least, points to the danger of transferring other subjects, such as chemistry and botany, to the preliminary list, as urged by some lecturers. Any student entering our schools with such knowledge would be at a great advantage, but to enforce it might diminish the supply of practitioners too suddenly for the public to submit.

Dr. Cayley, at the Middlesex Hospital, as we have already stated, touched on the London University examinations with great discrimination. One scarcely likes to complain of too great stringency, and yet there is danger even in that. It is a fact that men who have taken high honours at the London University have been found sadly deficient in certain kinds of knowledge that cannot be obtained from books. The London graduates are obliged to take other diplomas under our present system, and this is a point deserving the attention of the Senate. We do not become doctors for the sake of passing examinations, and every examining board ought to consider the wants of the public and the real requirements of the practitioner. Let us turn from this to the Scottish Universities, which now require a year's residence. To all who can afford to do so it would be of permanent advantage to spend a year in one of the great Northern Schools of Medicine, and in that way they would take a degree which is every year increasing in prestige, and they would reap the advantage of a year's study under celebrated Scotch professors. This fact alone should render the London University more thoughtful of the career of its men *after graduation*.

Mr. Gascoyen boldly took up another subject—the amalgamation of the London Medical Schools. This topic must come to the front. The Parisians were lately envying us. Many among us seem to have been envying them. Perhaps the best plan of all would be a medium. We see defects in the multiplicity of schools, but they are more tolerable than complete centralization and only one Faculty.

At Queen's College, Birmingham, Professor Berry succinctly stated what we had a right to demand of the Medical Council, and so introduced another question of medical politics. Taking, then, all these points as mere illustrations of what large subjects are embraced under the much abused name of medical politics, we are prepared to demand the attention of our readers to them, and, looking forward to the future, are encouraged at the tone of the Introductories this year, and hope that medical politics are no longer to be pooh-poohed.

LIFE INSURANCE.

Our American cousins, whom nothing daunts, are trying the experiment of doing business in life insurance on this shore of the Atlantic. There may be difficulties in the way of success; but they regard difficulties as things to be conquered and overcome. But there may be compensating advantages also. At any rate, a New York Office would lose nothing by assuring English lives on the same terms as American.

The New York Life Insurance Company is one of those Transatlantic offices which have committed themselves to the bold venture. It lifts its front, we observe, in the very heart of London, of Manchester, and of Liverpool. A better time, perhaps, could not have been chosen. A statute has just come into force, the whole policy of which is drawn from arrangements of public laws and administration, under the restraint of which the New York and other American Life Assurance Associations have grown up, and are conducting business. If, therefore, Mr. Cave's Act affords guards and securities for those who, as policy-holders and their families, are in the hands of British Companies, the mere fact of a new candidate for favour among ourselves hailing from New York, should be, other things being equal, one great point of recommendation.

It is boldly affirmed that no American office, confining itself exclusively to *Life* Insurance business, has ever yet failed; and, assuredly, the one already named is not the least of those in either importance or success. We have companies of greater age, as is natural to an old country. But the New York has been in existence for a quarter of a century, and, during that time, it appears to have assured 73,000 lives, to have paid policies to the amount of £1,152,000 sterling, with another million in cash consols; yet retaining in hand a third of a million after the discharge of every liability.

The mutual method, the proprietary method, and a mixture of the two—all have their advocates and admirers in this country. The tendency of modern opinion, however, is in favour of mutuality. If, indeed, the tone of Parliament and of the Press, in connection with the late panic, and with the debates on Mr. Cave's Bill, may be relied upon, there is a growing inclination among us to regard the policy-holders as having, not merely the first and chief claim upon their own premiums and the fruits of them, but even an exclusive title to the fund, which is formed by their contributions, and to the proceeds of it, less only a rigidly economical charge for office expenses.

This being so, the New York Life Insurance Company, being purely mutual, presents itself under an aspect which might be expected to prove attractive to the British public.

Another advantage which it possesses in common with any American office that might solicit our custom, is the fact that in the States money yields a higher rate of interest than either in Great Britain or on the Continent of Europe.

The laws of the State of New York have made a provision with respect to life-policies which commends itself

to every rightly-constituted mind. They cannot be attacked by creditors. Even though the assured person should die insolvent, his widow and orphan children would derive the full benefit of his providence. We presume, though without consulting the text of the law, that they would not be able to claim upon a policy assigned for valuable considerations by the original holder to another hand.

Besides the general advantages belonging to an American office as such, the New York, we observe, puts in several special claims, particulars of which may be found in their prospectus, one of them being, that the Company is the originator and sole issuer of "non-forfeiture investment policies." This kind of policy, on payment of a yearly sum, assures to the holder, on attaining a specified age, a certain sum, together with all the profits and payments made; or, in the event of intervening death, his surviving representatives will receive all the money paid in, together with the accumulated profits and amount insured.

Notes on Current Topics.

About the War and Wounded

A GREAT question is as to the supplies in Paris. The circular which anticipated the death by famine of hundreds of thousands at the capitulation may only foreshadow what may occur before the inhabitants and garrison yield. What may occur none can tell, and the data on which to form any judgment are few. By balloon, amongst other news, we naturally note that the Commission of Health have appointed committees to study the best way of utilising the blood of the animals slaughtered, a new system of saving 20 per cent. of grain, and the best plan of cooking whole grain. This seems to point to scarcity of meal and scarcity of flour, and it illustrates a well-known fact that Paris is badly off for mills to grind her corn. The measures may be adopted early intentionally, but we are assured positively that the supply of meal has been limited by command of the Government.

***

Hippophagy may triumph in the beleaguered city as it has done in Metz. We have little doubt that many of the cab horses and omnibus horses have already been slaughtered. There must be hundreds of little use, and their forage may be more valuable than the animals themselves. It would be better to eat them before they get thinner.

***

The prices of meat and bread are fixed by the authorities. Other commodities have risen. Eggs are threepence each. Fresh butter went up to ten francs a pound and then disappeared altogether. Salt butter is five or six francs a pound. Veal fat boiled down as a substitute is two francs. Stories like these show what a mass of misery may be in store for the devoted city. Fish, of course, is not to be expected. But milk—how about infants and invalids deprived of this?

***

A number of surgeons have arrived in Germany from America to offer their services for the sick and wounded.

Dr. Siemon, of the 4th Prussian Field Hospital, has spoken in high terms of the ladies who, with Dr. Luzeron, went out from the Tottenham Deaconnesses Institution in time to help after the battle of Gravelotte. We have heard from many sources of the invaluable services rendered by ladies who seem to be full, not only of sympathy but of ready wit, to turn to the best uses whatever they may find to hand. It is the old story of woman's ministry—

"When pain and anguish wring the brow."

***

The *Daily News* is raising a fund for the peasantry of North Eastern France, who are in a state of famine. Some £3,000 has been subscribed, and a good deal of provisions sent out. We have no doubt of the value of such a plan, of the urgency of the case, or the ability of the gentlemen sent out to superintend by our contemporary. We hope there is no chance of such food being confiscated by the Prussians, who seem rapidly to be degenerating, and if the war lasts long will become complete barbarians.

***

Dr. Thudichum has sent home an account of the Field Hospital we lately noticed as under his care. Mr. Simon has now left him for a town in Italy to recruit his failing health. Dr. Dupré, of the Westminster Hospital, has superintended the arrangements for water. The hospital is on a good soil, and ventilation has been attended to. There are ten assistant-surgeons (qualified) and five dressers. Dr. Thudichum and Mr. Simon both speak highly of all. We are sorry to observe that pyæmia, typhus, and dysentery have all been met with in so well arranged an hospital. What may they not do in other places where the sick and wounded may be conveyed? A bale of common oakum sent out was useless. It should be all carded, and Dr. Thudichum thinks it would be still better carbolised.

***

Around Metz we have already stated how serious is the amount of disease. We cannot expect it to decrease. Cattle plague, too, must add to the sufferings of the besieging army. But what of inside Metz? Could we get a reliable account of what is passing within the fortress we might find sadder scenes than many think about. Much is said, but anything reliable cannot be gathered. We can hardly hope, however, that the mass of human beings within are as healthy as the Government of Tours professes to know. Disease and death are probably enough rapidly reducing the ranks of the defenders. Professor Frerichs has been sent from Berlin to investigate the amount of disease round Metz.

***

It seems clear that some ambulances have had a surplus of useful articles of a particular kind, while others have been without these very things. Even in regard to chloroform this has happened. No doubt the haste with which they had to be despatched is the cause of this unfortunate mistake.

***

The German Aid Society has distributed sanitary tracts to a large extent—a few paragraphs relating to water, food, bathing, and other points of importance to the health, have been put in a popular form and freely given to the soldiers for their guidance. This seems a very sensible thing. Campaigning may be made more dangerous by ignorance, and many a soldier may save his life by mastering his tract.

The Germans, very wisely, continue to distribute their wounded as widely as possible. Several new modes of transport have come into use. By a plan of Professor Esmarck's, litters are hung up in railway trains by strong india-rubber rings, and patients ride thus with comfort when it would have been impossible to move in olden times.

***

The steamer *John Bull*, chartered by the National Society for Aid to the Sick and Wounded in War, sailed from the Royal Arsenal, Woolwich, last Thursday evening, with an ambulance train, complete in all its arrangements, and intended to operate in the neighbourhood of Paris. The personal staff consists of Dr. Thomas Guy, Deputy Inspector-General of Hospitals, who will be director and principal medical officer; Mr. Reginald Shee, secretary, Mr. J. S. Young, of the Army Control Department, commissary; Surgeon J. H. Porter, 97th Regiment; Staff-Surgeon Tertius Ball, Surgeon W. G. N. Manley, V.C., Royal Artillery; Staff-Surgeon J. Jameson; and Assistant-Surgeons M'Nalty, Power, Moore, Melladew, Macrobin, Malcolm, and Barroll. The stores shipped on board the steamer comprise eight ambulance waggons and twelve store waggons. The hospital will consist, unless a building be set apart, of twelve hospital marquees and twenty bell tents which will accommodate at least 200 patients. Provisions sufficient for 200 patients and 100 attendants for ten days accompany the ambulance, and a regular system of supply weekly will be organised by the society, with Havre as a basis. Lord Bury will meet the ambulance train at Havre, where he has been for some time purchasing horses and engaging drivers, and it will move forward without delay towards Versailles.

***

The *Indian Medical Gazette* devotes the chief place in its last issue to a review of the military medical organisation of France. The information on which the notice is founded is derived from a recent work, "De la Mortalitè de l'armèe" published by M. Chenu, and favourably criticised by M. Tuboulage in the *Revue des Deux Mondes*.

***

The two great evils that are complained of are mistaken economy, and the vice of centralisation that subordinates the Medical Service to the Intendance. Alongside of the combatant army is the second army of supply, which is termed the Administration. This is represented at head-quarters by one man, the Intendant-en-chef. He is responsible to the General for supplying all that is necessary, and to the Government for economy and control. In his hands are the supply of food and necessaries, transport, pay, hospitals, and general control. It is impossible that such different specialties can be efficiently combined. Hovering round armies are enemies usually more deadly than those they have to meet in the battle-field—typhus, cholera, and other zymotic diseases, which have always been the scourges of densely aggregated bodies of men like armies. As much special science and skill are required to combat these, as are required for the strategy and tactics of the campaign. During the Crimean war the French lost 95,000 men; of these 10,000 were killed in battle, about an equal number are calculated to have died of the effects of their wounds, leaving about 75,000 deaths due to disease, mostly zymotic and preventible. In the winter of 1856-57, 19,303 cases of typhus were admitted, of whom 10,278 died; while the English, with a third of the strength, had only 31 cases, of whom 17 died. The duty of the Intendance was honestly and faithfully to carry out everything according to regulation. There was an order from the bureau that no field hospitals were to be made, except in the Crimea. As long as the minimum of cubic space was supplied, the intendant had done his duty; crowds of fever patients were emptied into the hospitals at Constantinople, and it was in vain that the medical officers demanded barracks, bivouacs, space and air in any shape, to combat the epidemic. The theory is, that the surgeon is all-powerful at the bedside of the patient. He can bleed, blister or purge as he thinks best; but the hospitals are established, medicines are supplied, the hospital corps is directed, and transport authorised by the Intendance.

Clinical Society.

The first meeting of this Society was well attended, the President, Mr. Paget, occupying the chair. There seemed a slight feeling of disappointment when the President proceeded at once to business without gratifying the meeting with some of his excellent observations as a short preliminary address.

Mr. Spencer Watson exhibited some well-marked cases of parenchymatous keratitis in process of cure, drawing attention to the association of this affection with a rheumatic diathesis in the system.

Dr. John Harley narrated a most interesting case of intra-abdominal abscess, resulting from an injury inflicted by a restiff horse. The patient was a country surgeon, seventy years old, and for several weeks his life was in great jeopardy; after the loss, however, of a considerable quantity of purulent matter by the bowels, the patient made a good recovery, and eighteen months after the accident was able to ride and drive as usual.

Dr. John Ogle read his notes of a case of tetanus in St. George's Hospital, cured by ice applied to the spine, and belladonna given internally.

A good discussion on the therapeutics of tetanus followed: Mr. Croft said he had certainly seen recovery follow the administration of chloral, while he had found the calabar bean, given in full dose, quite inert. The President had seen a case treated with chloral without the least benefit; one case he had cured by the inhalation of oxygen; but in the next that came before him he tried this same remedy, but it had no effect whatever; as yet we were much in the dark as to the treatment of tetanus.

The Threat to Destroy the New Boulevard.

In Wednesday's *Times*, under the head of "City Commission of Sewers," we find the following paragraph:—

"In answer to Mr. Elias Davis the engineer (Mr. Haywood) said he believed it was the intention of one of the City Gas Companies to open up the Poultry in a short time to lay down pipes; that it would occasion no injury to the asphalte, and the repairs would be quickly made. He added that he informed the company in question, before the paving was undertaken, that the Commission intended to take up Cheapside and the Poultry for the purposes of the work."

Is it not really too bad that as soon as we are delivered from the fearful misery of our old granite in one short

street, it is to be handed over to the natural enemies of our thoroughfares. Let us hope the new asphalte may stand it well, and then perhaps we may get more of it.

The Curtain Falls.

Now that Margaret Waters has paid the last penalty of the law, we cannot refrain giving her credit for her becoming conduct during the few days preceding her execution. The woman's behaviour indisputably proves that she was not thoroughly depraved, but that she was rendered debased, and that she committed acts for which she deservedly suffered, through the iniquity of others, prompted by want, and the exorbitant demands made upon her by a nefarious, scheming son of Shylock. She did not become bad at once ; step by step she became hardened to the horrible traffic in infant life ; their innocent lips found no compassion in her breast, any more than in the unnatural parents who deserted their own offspring, and confided them to what they knew must be sure death. She became poorer month by month as she followed the profession of a baby-farmer ; and, for the sake of obtaining money to supply her wants, she was ready to carry out any villainous act with regard to the infants committed to her care. We do not believe the woman ever directly stamped out life, but if health flagged, and disease invaded the children of the farm, no effort was made to save them. Those in the background, who breathe the free air of heaven to-day, who abetted this woman, encouraged her in her evil trade, and gave into her care their children, are virtually as guilty as she, who lies within the precincts of a gaol, and has just expiated on the scaffold all she had to give in return for the lives she neglected, and allowed prematurely to pass away. We publish to-day a letter from a correspondent, who asks that seducers be ranged in the same category as baby farmers ; or, to employ Dr. Waring-Curran's own words, that the act of seduction be punished as a criminal offence. We enter heartily into the suggestion. Were *seducers* unknown to us, possibly Margaret Waters, with her more than ordinary intelligence for women of her class, might have wafted into some honest means of fighting honestly and honourably the great battle of life, and, instead of being as she is at the present, a degraded corpse, have been a useful member of society. It has been otherwise ordained, and, all things considered, since baby-farming does exist to so alarming an extent, we cannot regret the single life which has paid the penalty of the law. Considering the revelations made at the time of trial, and the very awful (to those whom it applies, if they possess feeling, or retain a spark of humanity or christianity in their hearts), accusation, that she died not alone for her own shortcomings and evil propensities, but for many who cruelly connived with her in secretly ridding the world of those who should be dearest to them. The death of Margaret Waters is the death warrant to seduction as practised so openly, so fearlessly, and so infamously at the present time. It is, as Dr. Curran says, the root of prostitution, the nest for baby-farming. If seducers were punished—and we only want the act of Parliament to allow it, and it will be quickly done—as criminals, the number of illegitimate births would soon rapidly decline, and the great evils of prostitution, ostensible and secret, with the consequent ravages effected by venereal disease, would be found to decline too. No grade of society, no profession or body of men is without well-known seducers. Seduction to these morbid minds becomes natural and of little consequence ; they perfect their cruel ignominious tricks only too easily without having anything to fear. Cowards at heart, they only need the strong arm of the law to be held out and they will quickly desist. A few examples, and female society will be saved the scourge which ever threatens, and only too often strikes home—strikes destruction to the victim, endless misery, privation, disease, and an early grave, whilst the breath of the destroyer withers all the comfort and united happiness of a once quiet home. We repeat, Margaret Waters has died for others as well as herself. We ask the co-operation of all our brethren in trying to carry into effect further legislation on this important topic, and we shall not cease until we obtain for the act of seduction a criminal punishment.

Snubbing a Member.

The proceedings of the Convocation of the Queen's University, Ireland, on Tuesday week, were attempted to be made formal and uninteresting by a process of management which ought not to pass unnoticed by any journalist interested in the success of a body which claims to be the National University for the granting of medical amongst other qualifications. The meeting was held under the presidency of Sir Robert Kane, the Principal of the Queen's College, Cork, and whatever view may be taken of his conduct in the chair, we are bound to acquit that gentleman of any *mauvaise honte* or undue timidity in the exercise of his powers. The adoption of the report having been moved and seconded with the proper amount of complimentary adjectives, a Mr. O'Donnell desired to move an amendment, but was peremptorily informed that the motion had been put and carried, against which decision he protested, saying that he had waited to hear the opinion of the "No's" asked, and had not heard the Chairman put the question.

While ruling that the motion had been disposed of, the Chairman, nevertheless, consented to Mr. O'Donnell moving his amendment, which declared the report to be deficient, but finding its terms not to his mind, the Chairman immediately declared the amendment informal, and refused to receive it, recommending Mr. O'Donnell to bring it before the Senate—a tribunal in which neither Mr. O'Donnell nor any other person outside the official circle has much confidence.

The following squabble then ensued :—

Mr. O'Donnell—I would beg to take exception to a portion of your ruling—(cries of "Chair")—that convocation is not the place to discuss these important matters.

Chairman—It is not open to any individual member to take exception to the ruling of the Chairman. I cannot hear you further on the subject.

Mr. O'Donnell—In that case I beg to move the rejection of the report. I speak against that report, which if we adopt it will go forth to the world as our opinion.

Chairman—I beg leave to rule, as it is necessary to preserve order in an assembly such as this, from the course the matter has taken, that the report was read. Professor Nesbitt moved its adoption, and having been seconded it was put from the chair and declared carried.

Mr. O'Donnell—I beg your pardon, you never asked us ; and never hesitated, to give an opportunity for a speaker to move an amendment. There was not the slightest opportunity ; I carefully listened for the smallest delay in your voice, and then I addressed you. I

protest against the idea of an important motion being declared carried without full liberty being given to the members of Convocation to express their opinion upon it.

Chairman—I have ruled that this resolution has been adopted ; we have proceeded to other business, and I shall not hear any further remark upon it.

Mr. O'Donnell—Mr. Chairman, I beg to insist that the motion was not declared carried within my hearing, and that there was no time given for speaking ; that furthermore, inasmuch as you allowed the proposal for an amendment, you will necessarily permit me to speak. It is now too late to go back. You have stated that it was from courtesy you allowed me to speak. I say I have a right to speak, and I protest against my mouth being shut on this important occasion (order, order).

Chairman—That does not in the slightest degree alter the course I have stated. I have declared the motion carried. As a matter of courtesy I allowed you to show me whether you had any *bonâ fide* amendment to propose. Your amendment I found not consistent with the order of proceedings, and I declared I would not receive it (hear, hear).

Mr. O'Donnell—If that is so, has a member of Convocation power to move that the Chairman do leave the chair ?

Chairman—You have—that is if the Convocation think fit.

Mr. O'Donnell—I beg to propose, in order to mark my extreme dissatisfaction at the course you have adopted, that you leave the chair.

Chairman—I have just consulted the Clerk of Convocation, and having read the rules I believe it is not competent for a member of Convocation to call for the removal of the chairman.

Mr. O'Donnell—Then I beg to propose that this house do now adjourn, inasmuch as I feel that fair liberty is not given to proceed.

Mr. O'Donnell again rose, and inquired what time might be given in protests ?

The Chairman—If you tell me what the protest is, I will then be able to answer your question.

Mr. O'Donnell—I am forbidden to protest. I don't get time to do it, and I now leave this Convocation, never to enter it again. I shall take care to tell the public of the manner in which I have been prevented from speaking.

The Chairman—In the proper time, and in the proper place, you will get liberty to speak.

Mr. O'Donnell—I was denied the right of speaking. I spoke at the proper time, but the authorities of the University dare not hear the bare truth told.

Mr. O'Donnell then left the hall.

Whether Mr. O'Donnell be characterised as an independent member of Convocation or a troublesome person, the effect of these proceedings on the public mind will be the same—a very strong feeling that the authorities of the University desire to suppress the discussion of debatable questions, by relegating them to their own tribunal, the Senate, and to make Convocation useful only for the purpose of humbly agreeing to all that the governing body puts forward. It is quite possible that Mr. O'Donnell's views are objectionable ; of that we know nothing, but we do know that a resort to such means to put him down, enunciating decisions, and immediately reversing them, is undignified, despotic, and, we believe, perfectly illegal. In our opinion, Mr. O'Donnell was perfectly in order in every one of the motions he made, and Sir Robert Kane entirely irregular, and acting *ultra vires* in refusing to hear him.

The Sanitary State of Lincoln.

As we predicted, an enquiry was opened by one of the Commissioners from the Home Secretary on Wednesday, in order to enquire into the sanitary state of Lincoln. There were legal representatives for the promoters, for the Town Council, local Board of Health, and for the memorialists who petitioned the Board against the scheme. The enquiry still proceeds. Already the evidence of architects and leading doctors prove the inefficiency of sanitary arrangements. We forbear making any comments until all the evidence is fairly before us, but we cannot refrain prophecying that the member of the local board who pronounced the report of Dr. Harrison to be a lie, will have the epithet thrown back upon himself, and that Mr. Maltby will see the fallacy of his statement that the laudable object of stamping out disease is to bamboozle the town. Our contemporary, *The Lincolnshire Chronicle* merits our warmest approval for its persistent advocacy of the efforts made by the medical men of Lincoln, and for the able manner in which it has so materially helped to bring about this investigation, which cannot fail bringing home disgrace to the doors of a certain clique in Lincoln.

The Sanitary Committee of the Dublin Corporation.

The Public Health Committee of the Dublin Corporation does its best to disconnect itself from that notorious body by a most creditable activity in the discharge of its duties. Its members really appear to be the only members of the Town Council who fulfil any useful purpose, and it is to their honour that they don't follow the example of their colleagues, and shirk all disagreeable or responsible duties.

The Sanitary Reports for September were submitted at the last meeting of the committee, and it appeared from them that during that month 38,000lb. of beef, 1,200lb. of bacon, 9 barrels of herrings, and 2 cwt. of other fish, and 11 cwt. of fruit and vegetables—constituting a total weight of about 43,000 lb.—were detected by the sanitary staff, and confiscated as being unsound and unwholesome, and utterly unfit for human consumption, for which it was intended.

A resolution was adopted directing the attention of the sanitary officers to the numerous complaints of the frauds now extensively practised in the adulteration of milk and butter.

Six persons were fined in sums ranging from £1 to £12 for the possession, for sale, of adulterated food, and one for the sale of adulterated porter.

Two hundred and thirty summonses had been served, and 220 convictions obtained in sanitary cases during the month, ten cases standing over. In no instance was any sanitary proceeding dismissed during the month.

272 dwellings in which infectious or preventible diseases had occurred were inspected and cleansed. In six instances chemical disinfection was found necessary.

1,169 articles of clothing were sent for disinfection to the Corporation Hot-air Chamber at Marrowbone-lane.

In Dr. Mapother their Medical Officer, and Dr. Cameron their Public Analyst, the Corporation has two invaluable servants, and we earnestly trust that now that the obstacles to the initiation of the system have been surmounted the sanitary *surveillance* of Dublin will never again be allowed to fall into disuse.

To one point in the foregoing report we take exception. It is but little use that the inspectors detect and seize diseased meat or adulterated articles, so long as the rascals

who are guilty of these frauds are shielded from publicity by the concealment of their names. The patronage of these gentry is too valuable for the daily papers to disoblige them, by making known their misdeeds, but the Committee have no interest to subserve other than the protection of the public, and it is, we consider, part of their duty to put the public on their guard by publishing the names of persons detected in selling diseased meat or sophisticated articles.

Funeral Cars.

We desire to call attention to the funeral car in common use in provincial districts and country villages, wherein the coffin is placed beneath a row of seats upon which the mourners sit. We have received intelligence of a case which should act as a caution to others. A girl dies of malignant scarlatina. Her remains placed in a coffin, are deposited in a receptacle underneath the relatives who sit above; in a week or so, every single person who occupied a seat in the hearse is struck down with scarlatina. It is to be presumed the wood of the coffin was as bad as the partition of the car, which separated the dead from the living, was defective. If such vehicles are still to exist, and we question their utility, we advise the coffin to be placed on the roof, for where the journey is a long and necessary tedious one, and the wood of the coffin new and emanations from the dead body likely to occur, we consider it highly detrimental to the health of those who desire attending the funeral to sit in such a funeral car.

Over-crowding in the Upper Classes.

We have heard enough of the over-crowding among the poor, and are apt to forget that the same evil may occur in houses of high rent and in aristocratic positions. The other day we encountered as out-patient at an hospital, a housemaid in one of the clubs in Pall Mall, and thinking her symptoms due to want of fresh air, we questioned her as to her habits, and elicited that she occupied part of a bed-room in the club-house in which seven of her fellow-servants also slept. This, we consider, demands the investigation of the Committee who cannot wish to breed fever in their club-house.

Eggs—How to Keep them.

The value of eggs in the sick chamber is only too generally known to be commented on, our object is to give timely warning that this most valuable food, for which no substitute is to be found, should be economically dealt with, as a very great scarcity must inevitably result. We need expect no importation of French eggs this season, the consequence will be the supply of English and Irish eggs will be inadequate to the demand. We recommend hospital authorities, and all those who will likely need eggs in mid-winter, to store away a supply now that they are plentiful, and comparatively inexpensive. The best means of preserving them is to pack them in salt, with the smaller end directed downwards. The "buttering" system is expensive and uncertain, but packing them in salt so excludes the air and keeps them safe, that the discovery of an unwholesome or decomposed egg is the exception. Fowls may be induced to keep laying by feeding them on morsels of uncooked beef and fat, and by mixing a little Cayenne pepper with their food.

Army Medical Department.

Staff-Surgeon Jameson, doing duty at Armagh, has been ordered to proceed to the Seat of War to join the International Society's ambulance. Staff-Surgeon Birnie and wife, Staff Assistant-Surgeon Pont, and Staff Assistant-Surgeon Kearney embarked in H.M.S. *Serapis* at Portsmouth on Saturday, for conveyance to India. Staff-Surgeon Burke has been ordered from Dublin to Aldershot, to take medical charge of the 2nd Battalion, 22nd Regiment. Staff Assistant-Surgeon Canny has been transferred from Dublin to Ballina, Staff Assistant-Surgeon Flood from Gort to Dublin, and Staff Assistant-Surgeon O'Malley to Boyle. Staff Veterinary-Surgeon Gardiner has arrived at Dublin for duty, vice Gloag, to half-pay.

Royal College of Surgeons in Ireland.

At the Quarterly Examination held on the 11th and 12th inst., the following gentlemen passed the first half of their examination for the Letter's Testimonial, viz.:—Joseph Athearn, Edward Morris Day, William Donovan, Jeremiah J. Donworth, Robert Drury, Michael Fitzgerald, Thomas Sargent Floyd, Edward Mulany, Joseph William Neligan, Domenick Rice, John Ryan, and William H. S. Westrope.

The subjects of the Fothergillian Gold Medal, value twenty guineas, offered by the Medical Society of London, are, in 1871: Some subject in Obstetrics (including the Diseases peculiar to Women). For 1872: On Croup.

The next Primary and Pass Examinations for the Diploma of Member of the College of Surgeons of England, will commence on the 5th and 11th of November respectively; and the First and Second Professional examinations for the Fellowship on the 19th and 23rd.

The next Meeting of the Pharmaceutical Society of London will be held on Wednesday evening, November 2nd, at Eight o'clock. The following Paper will be read:—"On some of the Infusions of the Pharmacopœia," by Mr. J. R. Barnes.

The Session of the Medical Society of London commenced on Monday last, October 17th, at 8 p.m., when an Address was delivered by John Gay, Esq., F.R.C.S., President, entitled "Surgical Art and its Limitations," followed by "A Practical Account of Basic Disease of the Lung," by Andrew Clark, F.R.C.P.

In the Faculty of Medicine of the Queen's University in Ireland, fifty gentlemen have within the last year been examined for the Degree of Doctor, of whom forty-three have passed; thirty-six for the degree of Master in Surgery, of whom thirty-two have passed; and 131 presented themselves at the First University Examination in Medicine, of whom ninety have answered to the satisfaction of the examiners.

Dr. Pantaleoni, who some years since was banished by the Pope, and who has sometimes contributed to our columns, has been appointed Inspector of Hospitals by the new Government of Rome, and will, we hope, again favour our readers with some articles. Professor Maggiori and Dr. Toscani have also returned to their posts at Rome.

SCOTLAND.

EDINBURGH.—The foundation stone of the new Royal Infirmary was laid on Thursday last by the Prince of Wales. The event was made the occasion of a great masonic display, it being the first masonic act in Scotland performed by the prince as patron of the order. The Princess of Wales was present at the ceremony.

ON Wednesday the Prince and Princess of Wales visited the Sick Children's Hospital, and inspected the wards under the guidance of Dr. Matthews Duncan, Chairman of the Board of Directors, Dr. Peel Ritchie, and Dr. Gamgee, acting physicians. The utmost satisfaction was expressed by their Royal Highnesses with the arrangements and comfort of the wards.

WE are glad to learn that the University of Aberdeen is fully alive to the propriety of establishing bursaries in connection with the Faculty of Medicine, and that measures will shortly be taken for accomplishing this object.

DR. ANGUS FRASER, Aberdeen; Dr. Fiddes, Aberdeen; and Dr. Trail, Moneymouth, have been appointed Examiners in Medicine in the University of Aberdeen.

SPECIAL CORRESPONDENCE.

[LETTER FROM OUR SPECIAL CORRESPONDENT.]

[This letter has been held over in consequence of the recent pressure on our space by the Congresses, &c.—ED. MED. PRESS.]

PARIS.

I SAID that I would endeavour to send you a few notes from the able lectures, recently delivered by Dr. Peter, on "Diseases of the Heart," at the Hôpital de la Pitié. Dr. Peter remarks that all observers agree in having noticed that the aortic valves are more frequently injured in old age than the mitral valves. This is because the sigmoid valves form part both of the heart and of the aorta. The symptoms of disease of the heart in old persons are less distinct than among the young, because the heart is old, and the blood which it sends forth is feebly launched, and thus less violently directed against any obstacle than it is in the vigorous adult; but if you listen carefully at the base of the heart in old persons with intermittent pulse, you will be able to detect a bruit. The fourth left intercostal space is the best position for listening to such bruits, near the juncture of the fifth cartilage with the sternum. As the organism is aged, and the sensations less acute, palpitations—those painful symptoms of heart disease—are either not perceived, or are not felt. Thus, we see old persons with clearly marked heart disease, and with tumultuous disorder of arterial pulses, denying that they felt any kind of pulsation, and quite unconscious of their pulse being intermittent. In old persons, also, the functional disorders of other organs are far less marked than in the young. The engorgements of the viscera take place much more slowly; but, if you listen carefully at the base of the thorax, you will detect fine râles, indicating a permanent condition of œdematous conjestion, and the malleoli are often œdematous. Heart disease is common in old age; but frequently unrecognised. The use of alcohol produces more rapidly than old age the using up of the tissues of the heart, and is thus only premature senility. Budd has pointed out the frequency of heart disease among drunkards, and we have shown by numerous autopsies of drunkards, that their heart is always injured, and usually most gravely, as in old persons, in the aortic valves. Rheumatism and chorea, a disease connected with rheumatism, are causes of acute valvular disease, as old age and alcohol produce chronic disease. Gout rarely attacks the heart; it is the great vessels it injures. Syphilis, when it attacks the heart, injures the muscular tissue rather than the endocardium. Eruptive fevers, and more particularly scarlatina, when intense, may produce heart disease. The endocarditis of scarlatinal, or puerperal, or typhoid origin may be the starting point of an organic affection of the heart. In the last named disorder there is found frequently after death of typhoid fever, epithelial proliferation on the mitral and sigmoid valves. The lesions due to alcohol are frequently seated on the ventriculo-aortic valves, and are frequently complicated by a fatty addition to the heart at its base, and along the anterior coronary artery, just as takes place in old age. In rheumatism, again, the endocardium is alone usually affected, and especially the mitral valves. Scarlatina, of all eruptive fevers, is the one which most frequently gives rise to endocarditis. We ought to listen daily to the heart in scarlatina patients, so as to be able to combat any endocarditis which may arise by means of blisters, &c. It is probably in rheumatic persons that the fever causes disease of the valves.

Dr. Peter observes that it would seem as if the knowledge of the exact relation of the different parts of the heart with the thoracic parietes ought to furnish information useful at the bedside, and permit us to precisely localize the seat of abnormal sounds. But nothing is more illusory. The heart, when diseased, is of larger volume, and thus its relations to the chest walls alter. According to Gendrin, among others, outside of the left edge of the sternum are found the two-thirds of the pulmonary artery and one-third of the aorta. The heart's apex beats normally between the cartilages of the 5th and 6th ribs at lowest, or between the 4th and 5th at highest. According to Luschka, cited by Dr. Gairdner—1. The aortic orifice corresponds to the third right chondro-sternal articulation; the pulmonary orifice to the most internal part of the 2nd intercostal space a little higher. 2. The left auriculo-ventricular orifice is situated behind, and to the left of, the aortic orifice, in the 3rd left intercostal space, one centimetre from the sternal edge. 3. The right auriculo-ventricular orifice is under the sternum, near the 3rd left intercostal space. All this is only true in health, and misleads when disease is present. The heart is fixed above by the great vessels, and free at its apex; so that when it is hypertrophied, its base remains almost motionless, while its apex descends, as also its valves. In some cases of hypertrophy, too, the base descends also. Now, all grave lesions, whether valvular or otherwise, in the long run, cause displacement of the point of the heart, and also of its base. On the other hand, the elongation of the organ, as well as the hypertrophy of the auricles, produces the descent of the orifices, so that all the relations of the heart to the chest walls are changed. For instance, in a patient in the wards, affected with aortic constriction, the bruit is heard, not at the level of the third *right* chondro-costal articulation, but at the level of the upper edge of the fourth left costal cartilage, near its junction with the sternum, whilst the point of the heart is felt to beat at the upper border of the eighth rib, whilst dulness finishes at the third. At the origin of the great vessels the dulness is six centimetres transversely.

Vivisections have shown that, during the diastole of the heart, the blood penetrates, by means of the vis-a-tergo and gravitation, from the auricle into the ventricle, without effort on the part of the auricle, which may be considered as a very dilated part of the venous system. There is, hence, no noise in this operation, even if there exist more or less considerable constriction of the auriculo-ventricular valve. The auricle, however, may contract on the last few drops of blood, and cause a pre-systolic bruit, coincident with the systole of the ventricle. But the stricture of the auriculo-ventricular valve must be considerable, in order that a pre-systolic bruit should be possible. It must be remarked that this same bruit is always likely to be followed by a systolic bruit, on account of the insufficiency of the valve in such cases; this same sound may continue

after the systole, and then is called pre-diastolic. It may be easily understood from this that the blowing murmur due to the constriction, as it tends to be heard chiefly at the point of the heart, and as the blowing murmur due to insufficiency tends to be heard most loudly at the base, there ought to be heard, in case of stricture coincident with insufficiency, a mean murmur heard neither most loudly at base nor apex, but at a point midway. M. Hérard says he has clinically observed blowing murmur at the apex in four cases, in which the murmur at the apex was double, and in three of these cases, where there was a *post-mortem* examination made, constriction with mitral regurgitation was observed. The following conclusions are adopted by Dr. Peter :—1. That the notions so precise as to the relation in health of the orifices of the valves of the heart to the chest walls are rather useless when disease is present, since then the relations are destroyed. 2. That the blowing murmur of the systole heard most loudly in the neighbourhood of, or at the level of, the fifth left intercostal space, where the heart's apex normally beats, is characteristic of mitral regurgitation, this point of the chest wall no longer corresponding to the apex of the heart. 3. That the blowing murmur of the systole, in the neighbourhood of the point where the heart's apex really beats, indicates stricture of the mitral orifice, and, *à fortiori*, if this murmur is pre-systolic. 4. That the blowing murmur during the diastole at the point, which would be characteristic of mitral constriction is problematical.

It is above all important in practice to remember both for the patient and the physician, not so much what is the exact lesion of the heart ; but that there is *a* lesion, and to be acquainted with the general condition of the subject of this lesion. There is no relation between the functional disturbances caused by a disease of the heart and the intensity of the murmur which exists so that the prognosis of this disease is not to be drawn from the seat of the lesion, but, it is in a ratio compound of the intensity of the lesion, its duration, the age of the patient, and his habits and force of resistance ; so that, if we must learn to recognise the seat and the nature of a cardiac lesion, we must also learn that this is a mere artistic satisfaction, and that the work of the physician commences here. What you have still to know, and what is still more important is, the state of the vascular system and of the organs of hæmatosis and the general state of the system, because in this it is that we must, and ought to, look for our therapeutic indications.

Corvisart said that " in the last period of cardiac aneurisms, we sometimes remark delirium, especially at night." Dr. Peter has seen cases similar to this in heart disease, and accounts for them as he would account for coma, somnolence, &c., mentioned by some authors in like cases. Cerebral hyperæmia supervenes caused by venous stasis in certain cases. Independently of the exacerbation of the different symptoms, the morbid temperature rises every evening to redescend each morning. The occurrence of nocturnal delirium in cases of heart disease is no exceptional fact, and has for its material causes a passive habitual hyperæmia of the brain, so that this delirium is the index of grave and habitual disorders of the brain circulation, and one of the proofs of the thorough disturbance of the whole circulatory process ; it shows, as Corvisart says, that the patient has come to the last period of his cardiac affection.

All lesions of the *left* heart first of all take effect on the hæmatosis, *i.e*, on the oxidation of the blood globules ; all lesions of the *right* heart affect hæmato process, or the fabrication of these globules. But, in spite of the localizers of heart affections, the sole practical consequence which would result from the notion of the seat of the lesion, *i.e.*, the knowledge of the more or less tardy apparition of the consecutive functional disturbances, does not follow from this notion, and, besides, the functional disturbances are precisely the same, whatever be the lesion of the heart existing. Both in cases of aortic constriction, and in mitral regurgitant, there soon takes place tendency to pulmonary congestion. Whatever be the primitive lesion, it affects gradually the whole heart, and travels from the left heart to the right heart. Consequently, the gravity of a heart affection of the left heart commences when the difficulty of the circulation of the lung commences : since this difficulty does not only prove stasis to exist at the left auricle, but becomes an initial phenomenon, after which the consecutive lesion of the right heart is about to appear.

Dr. Peter says with regard to the localisation of sounds, he takes as his stating point the left nipple, and considers two regions, one above, and the other below that nipple. Nothing more is necessary than to see whether the blowing murmur is heard in one or other of these spaces. 1. If we perceive a murmur in the sub-mamillar region, it is always with a first sound or a little before it, and is always due to a cardiac lesion (mitral regurgitant, or constriction). 2. If you perceive a murmur in the supra-mamillar region, it is sometimes with the first and sometimes with the second sound. In the first case doubt is possible ; when with the second, it is always cardiac, aortic insufficiency. As to a blowing murmur with the first sound, if it be rough, intense, without great propagation to the vessels of the neck, if the patient has not the tint of chloro-anæmia you all know you will conclude that you have to do with a constriction of the aorta. The pulse, small in the former, and large and compressible in the latter, will complete the diagnosis.

If there is anything rare in the world, it is the simultaneous existence of a heart affection with tubercles. Why is this ? The tuberculisation of the lung commences at the apex, because that is the part of the lung which does the least work. Now, in persons affected with heart-disease, these are habitually passive congestions of the basis of the lungs, and this causes the apices to become more active. This is, again, the reason why asthmatic persons are so rarely tuberculous or, in a great measure, emphysematous patients. Peter remembers but one asserted example of the existence of phthisis and cardiac disease and that was in a drunkard.

One very important question in morbus cordis is, what is the state of the vessels ? In respect to the pulmonary artery, its functional derangements manifest themselves long before we can observe any sign of material lesion. There is dyspnœa and anæmia to guide us. The dilatation of the pulmonary veins of the capillaries and of the artery, cause passive congestion of the lung with œdema, hæmorrhage, or inflammation, all of which we can judge of by the stethoscope. As soon as you perceive râles of engorgement of the lung capillaries, you may conclude that the pulmonary artery no longer compensates, and that its contracting power is partially conquered. In many cases, there results for the pulmonary parenchyma from its basis to the middle part of the lungs, a definitive condition of induration and of friability, a mixture of œdema, of hæmoptoic infarctus, of cirrhosis, and of partial inflammation, and finally, the lung becomes thus struck with functional incapacity. Such are the necessary consequences of the dilatation of the pulmonary artery, vein and capillaries. From this dilated state of the capillaries with congestion of blood in the vesicles, there occurs a difficulty in the oxidation of the blood globules, which explains the anæmia we notice in patients who do not cough. There is too much blood to oxidise in the wall of the vesicle, and too little air in the vesicle to do it with. You may, from such a condition, conclude that the patient has arrived at the second stage of his disease of the heart. This may endure several years, during which time the patient is always in danger in case he become affected by bronchitis, &c. In practice, the repetition of pulmonary accidents, such as sudden and intense congestion of the lungs or bronchitis, in the form of suffocative catarrh, hæmoptysis, &c., in a non-tuberculous person may make us think of morbus cordis. Good hygiene may do much in such cases ; but unfortunate working people may soon be overwhelmed by the disease. Among the wealthy such cases may last for years, whilst they are rare among hospital patients.

Is it possible to prognosticate what is the anatomical condition of the heart? We can certainly know the volume of the heart by percussion, but we possess no actual method of ascertaining if the augmentation of the organ is accompanied by a dilatation of its centres. If there be a valvular lesion, dilatation is probable as well as the hypertrophy. As to knowing whether the fibres are intact or fatty, we can only judge by the functions. It is only in the third period of heart disease, that the heart degenerates. The *arcus senilis* which might better be named fatty circle, since it is fatty and is observed in some young persons, is a very good sign of alteration of a similar nature in the muscle of the heart. If we have a fatty degeneration of the cornea, we may deduce from it immediately the existence of an alteration of like nature, almost certainly in the endocardium, in the lining membrane of arteries and in the muscle of the heart. These remarks were made first by Canton. Endarteritis and periarteritis are common in gouty persons, and angina pectoris likewise.

In my next letter I shall attempt to give you a few more notes from Dr. Peter. It may serve to keep up our courage during the existence of this terrible war, which I fondly trust, Mr. Editor, may not last much longer. If it does, our beautiful city must certainly be grievously injured.

Correspondence.

BABY-FARMING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I observe you do me the honour in your "Notice to Correspondents' column," of quoting a remark made by the Editor of a much respected contemporary *Public Opinion*, respecting a letter written by me on the subject of *Baby-Farming* The Editor of *Public Opinion* gives me the credit of being the first to advise the punishment of seducers in order to strike at the root of the great social evil of baby-farming, and that all seducers be punished if the evidence be strong enough to convict in a criminal court, according to the nature of the seduction, and the attendant circumstances of the case—to make, in fact, seduction a criminal act. Now, the suggestion originated not with me, but emanated from a writer of a clever editorial article in the columns of another esteemed contemporary *The Daily News*, who lucidly showed that so long as designing men practised the cruel act of seduction, that in spite of detective police, the speeches of Crown prosecutors, the charges of Chief Barons, the convictions of special juries, and the sentimental termination by a private execution in the interior of a prison, that baby-farming will continue. The root of the evil exists with the men. We all know the seducer, no town or country village is without him. I loathe attempting his description, well-to-do in the world, gifted with the art of pleasing, and blessed by nature with good personal appearances, he wins his heartless game easily, and some I know, boast of the number of half-crowns they pay weekly to condone their guilt, in another's weakness—the sufferer or the victim entangled into the meshes of the silken woven web. Upon half-a-crown she cannot subsist, and support her illegitimate offspring. She is deserted as a rule by the seducer, who despises her for her weakness, and she is destroyed for ever in the eyes of her relations. As in the case of a man, there is no retracing the step in the wrong path. She goes for work where she is unknown, and places the child in the hands of a *farmer*. Recent events disclose the last scene of the performance. All this time, Seducer, Esq., is at large, boasting perhaps over his exploits, and hailed by his admirers as a hero. It is as curious as it is disgraceful to remark how this sort of man is fawned upon by friends of his own sphere of life, and how enthusiastically he is received into society with open arms. In truth such a man, and there are only too many thus encouraged to go on in the evil work of destruction, and of ruining their poor dupes for ever. In order to control prostitution and ring the death-knell to baby-farming, seducers must be made amenable to legislation and punished according to the nature of the evidence adduced against them. What effect would such a law have upon our garrison towns? Upon the unmarried, well looking squire, ever on the *qui vive* to betray and to destroy? Prostitution must have a starting point, and Dr. Drysdale, or any one who has specially listened to the sorrowful tales disclosed by hospital patients, in the hour of suffering and repentance, could tell that ruin came through some one in a better position of life than the erring, that the tempter or the betrayer was not on the same level so to speak.

The question only requires agitation that attention may be directed to it elsewhere, and the clever suggestions of the Editor of *The Daily News* be brought to bear good fruit, for if it be desired to out-root baby-farming, I repeat seduction must be made a criminal act.

I am, Sir, your obedient servant,

J. Waring-Curran.

Oct. 13th, 1870.

P.S.—Since writing the foregoing, I find the following remarks made to-day, by our foster-brother the Editor of the *Law Journal*, called forth by the case of a tradesman, who at the Southwark Police Court, was ordered to pay two and sixpence per week for the support of the illegitimate child of a girl whom he seduced under the promise of marriage. These observations are worthy the source from whence they emanated, and I congratulate the *Law Journal* upon them.

"We denounce baby-farming, and yet maintain a law which renders it almost imperative. Why should not a man be compelled to fully maintain his offspring? At present the mother, if left without provision, cannot even by an appeal to the law obtain a sufficient support for her child. Instead of a maximum of 2s. 6d. we would raise it to 20s. a week—the magistrate to make an order according to the circumstances of the case and the position of the parties. Not only would there be less baby-farming, but the man, knowing his legal obligation to keep his offspring, would be disposed to make a fair arrangement without compelling the woman to appear in open Court."

I would add, *abolish the rule of the necessity* that exists, *of swearing the paternity of the child within a twelvemonth*. This is the next best step to the suggestion of *The Daily News* commented upon above.

WHAT IS WRONG? WHERE IS IT? WHAT WILL BE DONE WITH IT?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Aug. 21st.—A. B., a stout healthy young man, twenty-eight years of age, who cannot recollect ever having a moment's illness, ate his breakfast this morning as usual, and then took a book to read, the window was open and a gentle air was passing through the room. At 10 a.m., he felt chilly, which was almost immediately followed by rigors, or cold shivering; at 4 p.m., the skin is hot and dry, headache, mouth dry, thirst, countenance slightly flushed, loins painful, and general pain and uneasiness, nausea and bilious vomiting, some uneasiness over the epigastrium, bowels opened this morning; pulse 135, and full. This is a case of what is called typhus fever. What is the meaning of the word typhus? It is derived from the Greek, and means stupor. What is the meaning of the word fever? it is derived from the Latin, and means heat. The name of this disease is from two different languages, and means "Stupor, Heat, or Typhus Fever." But, where is it? The head aches, is it in the head? The skin is hot, the pores are closed, refuse to perform their usual functions, and the blood refuses to part with its watery portion in the form of perspiration, is it in the skin? There is general pain and soreness, is it in the muscles, veins, or nerves? The pyloric orifice of the stomach is relaxed, and the bile flows back into it which it rejects, is it in the liver? Is it in the lungs? There is increased respiration, is it in the kidneys? as their secretion is rather high coloured, or is it in the blood? The blood is the life of man, and from it everything is secreted pure or impure. Have the lungs absorbed a poisonous miasma and thrown it into the general circulation? Is the blood poisonous? What produced the rigors! What excited the heart's action? If the blood is poisoned it is in the whole system, and it will soon injure some vital parts. What about the stomach, as it has a most important part to play? The bowels have been freely opened, and what now is to be done with this stupor heat? We have diaphoretics, diuretics, and specifics, &c., &c., what will they do? If you draw blood from a vein and throw a solution of the nitrate of potash on it you see the result; and if it acts thus upon dead

matter, what action may it not have upon the living? It might neutralize or destroy the poison ; whatever is put into the stomach to do good must be absorbed. But, what have we to contend against here ? Certainly not typhus fever, or stupor heat ; what have typhus, or stupor, and fever or heat to do with it ? What keeps up the heart's action ? Certainly, neither the typhus or stupor, or fever or heat, the principal or chief enemy is that which caused the rigors, and it is keeping up the heart's action, it is in the blood and vitiates every secretion, what does the tongue say ? What about the stomach and the intestines ? There is air or gas in the intestines, will the stomach absorb anything now ? Petechia have appeared, what are they ? What caused them ? The artery deposited a particle of blood which the vein could not absorb, which shows great debility. What have the diuretics and diaphoretics done ?—Nothing—what should they have done ? Excited the skin and kidneys to action, would these lessen the heart's action, or carry off the poison ? were they absorbed by the stomach ? Stimulants are now given to excite the heart's action through the nervous system, what will this do ? Will it destroy the poison or alter the constituent particles of the blood ? I had a case once in which I gave a pint of brandy, and the patient recovered, after a long sleep of twenty-five hours, and a hard struggle against great debility ; but, in this case, the poison must have lost its virulence, its power must have been destroyed, but whether by exhaustion or the powerful stimulus, I cannot say. No, he has sank gradually, he is dead. What killed him ? No disease has been found in the skin, muscles, veins or arteries ; none in the liver, brain, or lungs ; the heart is sound, and we have only to look for the result in the stomach and intestines. It is with them we have been working since the commencement of our labours, and in them will be found the result of the cause. It is, I believe, an acknowledged fact that no two separate actions can exist in the system at once, at one and the same time. It is, I suppose, upon this principle that I have never lost a patient labouring under this affection whose system I could place under the influence of mercury. I have saved many by saturating the system with the nitrate of potash, and I have combined the saline with the mucinese with good results ; but much depends upon the virulence of the poison, if it is very active, I place my sole reliance upon mercury, and it has never failed in Africa, India, or any other places. It is strange to say that one has died from typhus fever, when we cannot tell what it is, at least, I cannot, nor could I ever find a man who could. People run from it as from a mad dog, without knowing what they run from ; they say that the "fever," "the heat" will catch them ; what is contagious or infectious in this ? The poison died with the patient, he could not exhale it from his lungs, though the poisoned blood passes through them, it seems to destroy the vitality or the oxygenizing principle of the blood, and produce a strange action in the terminal arteries and veins of the whole chylo-poetic viscera.

ALEXANDER LANE, M.D., R.N.

Chen, Salop, England, Sept. 23, 1870.

P.S.—If we, at the commencement, place the system either under the influence of mercury or potash, or both, we save the patient, or at least, in my opinion, give him a far better chance than by any other mode I know of, as if we leave until the absorbents of the stomach lose their action and cannot absorb what is thrown in, our chance is lost. If the patient recovers, no thanks are due to medicine, but either to the exhaustion of the cause or the strength of the constitution to resist. What is typhus fever, and how will you treat it ?

"CHLORAL HYDRATE."

A TRUE VERSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad to find your respected and spirited correspondent, Dr. Waring-Curran coming forward on the subject of Chloral Hydrate, which he truly says is an "over-estimated drug." Our profession is only too fond of new things, surgical toys, and therapeutical novelties ! An eminent Dublin hospital surgeon the other day, in conversation with myself, had reason to shake his head very seriously over the chloral. More power, then, say I, to Dr. Waring-Curran, and all therapeutists like unto him who have the courage to say what they believe, and who fear, so to judge from the boldness of their communications, neither to court displeasure nor cultivate favour. What about podophyllin ? What about pancreatic emulsion ? What about carbolic oil ? carbolic silk ? carbolised ligatures ? Where will hydrate of chloral be in another twelve months ? On the same shelf with lactate of iron and granulated tin.

Much time is lost—valuable to the patient, for his life not unfrequently is in the balance, because, as Dr. Curran says, over-drawn pictures effect more in the eye of the physician than is evinced by the patient's yielding to a rainbow treatment. *Veritas vincit !*

I am, &c.,

A DUBLIN PHYSICIAN.

Obituary.

THE LATE MR. RICHARD BARTER, M.R.C.S.

WE deeply regret to have to announce the death of MR. Richard Barter, M.R.C.S., at his residence at St. Anne's Hill, Cork, on Tuesday, the 4th inst. As regards his professional career, he studied at the London, Dublin, and Edinburgh schools of medicine, and gained his diploma at the College of Surgeons in 1828. We must state that by him the Turkish Bath was first introduced in England. As a literary man he was the author of "Lectures on the Turkish Baths at St. Anne's Hill, Cork," a treatise on the "Treatment of Cholera on Rational Principles," and he also contributed several papers to the MEDICAL PRESS relative to the same topics.

Medico-Legal Intelligence.

POST-MORTEM EXAMINATIONS AT HOSPITALS.—IMPORTANT DECISION.

THE decision in the matter between the authorities of St. Thomas's Hospital, and a person named Leverett, was on Saturday given by Mr. Ellison, the presiding magistrate at the Lambeth Police Court.

Mr. De Tracy Gould again appeared for Leverett, the complainant, and Mr. Poland for the hospital authorities.

There was one summons against Mr. Frederick Walker, the steward of the hospital, for causing the body of Everalda Matilda Leverett (wife of complainant) to be removed for anatomical examination from the place where she died within forty-eight hours of her decease. Mr. Richard Whitfield, the resident surgeon, was also summoned for having permitted the removal of the body within the time, but that summons on the last occasion was withdrawn.

Mr. Ellison, in deciding the case, said the summons was against the steward of the hospital for non-compliance with the provisions of the Anatomical Schools Act, the 9th section of which required amongst other things that forty-eight hours should elapse before the removal of a dead body for the purpose of anatomical examination. The case had been very properly described as a matter of great public interest. It was most important on the one hand that the feelings of surviving relatives should not be outraged by hasty or indecent proceedings, and, on the other hand, it was of equal importance that the researches of science, by which medical knowledge was extended, and by the prosecution of which alone it could be hoped to cope with disease, should not be fettered by unnecessary restrictions. The patient died under circumstances which made an examination advisable. The examination was conducted with decency and propriety, the regulations of the hospital being in no way departed from ; but it was conducted without the knowledge or consent of complainant. Although complainant had made no application at the hospital the whole of the day after the patient's death, it might not have occurred to the authorities that any objection was likely to be felt on the part of the husband, yet the authorities knew that he was aware of his wife's being there, and that he had been required and had agreed to bring her some necessaries ; that he had been at the hospital on the 16th September, and again on the 18th, when he saw the body and had expressed his intention to remove it on the Monday at half-past nine o'clock in the morning, and went at that time for the purpose. He (Mr. Ellison) therefore thought it would

have been better if the authorities had taken some little trouble and placed themselves in communication with the husband and ascertained his feelings in the matter before proceeding to the examination, and he would strongly urge upon the authorities that it would be advisable, whenever practicable, to take the addresses of the representatives of the patients, and to place themselves in communication with them before they proceeded to an examination. He was, however, obliged to come to the conclusion that there was no removal as contemplated by the statute in this case, and for that reason the summons would be dismissed.

The Complainant asked the magistrate whether he could carry the case further, as it was of great public importance.

Mr. Ellison said he could consult his attorney.

Mr. Poland said the authorities were fully prepared, and willing to meet any inquiry or further application.

Medical News.

The St. Bartholomew's Dinner.—This annual gathering took place on Monday evening week in the great hall of the hospital, when ninety-six old students sat down to dinner under the presidency of Dr. George Paget. Nearly all the medical staff were present, and the guests and visitors included the Rev. Dr. Bell, Professor Humphry, of Cambridge, Sir Trevor Laurance, Bart., Dr. Stenhouse, the Secretary of the College of Surgeons, Mr. Daniel of Ramsgate, &c.

St. Mary's Hospital Dinner.—The members of the staff, and the old and present students of this school dined together at Willis's Rooms, on the evening of Saturday, October 1st, Dr. Sibson, F.R.S., being in the chair.

Prizes Awarded at the Opening of the Manchester School of Medicine.—Third year Scholarship, value 20*l.* Mr. H. Reston, Manchester; first prize, value 5*l.* 5s. Mr. Webster, Manchester; second prize, value, 3*l.* 3s. Mr. C. Holmes, Ardwick. Second year Scholarship, value 15*l.* Mr. E. Bishop, Manchester; first prize, value, 5*l.* 5s. no award; second prize, value 3*l.* 3s. Mr. A. M. Edge, Rusholme; third prize, value 2*l.* 2s. Mr. R. T. Morris, Rochdale; fourth prize, value 1*l.* 1s. Mr. H. P. J. Price, Hulme. First year's Scholarship, value 10*l.* Mr. J. T. Hall, Rusholme; first prize, value 5*l.* 5s. Mr. J. Green, Bolton; second prize, value 3*l.* 3s. Mr. E. A. Birch, Rusholme; third prize, value 2*l.* 2s. Mr. F. W. Jordan, Manchester. Certificates of merit; Mr. F. Daniel, Crumpsall; Mr. G. Stansfield, Bacup. Mr. Turner's prize, 3*l.* 3s. Mr. E. A. Birch, Rusholme.—The following list of first, second, and third year men, who had obtained certificates of honour, was also read:—J. M. K. Buckley, H. B. J. Price, C. F. H. Kitchen, A. M. Edge, A. Kershaw, J. W. Sellers, G. Garside, A. Hurst, H. Reston, F. H. Walmsley, F. O. Bentley, J. Green, F. W. Jordan, C. L. Smithard, J. W. Whitehead, E. A. Birch, C. Holmes, E. M. Garstang, W. P. Counsellor, J. H. Cottam, J. Daniel, J. Hutchinson, H. C. Smale, R. T. Morris, W. Needham, J. C. Allen, P. L. Booth, J. F. Harrison, G. S. Stansfield, J. T. Hall, R. H. Hammond, H. W. Webster, H. P. Ilderton, F. H. Smelt, W. Swift, J. Hindle, J. H. Hall, J. T. Appleby, W. Holt, J. O. Smith, G. Morris, F. W. Buck, and R. Hartley. The students were addressed by Mr. Turner, and several of the lecturers to the Institution, who were loudly called for; after which the proceedings terminated.

The London Hospital Medical College.—The following prizes for the Session 1869-70., were distributed at the close of Dr. Sutton's Introductory Lecture, by Edmund Hay Currie, Esq., Chairman of the London Hospital House Committee,—*Clinical Medicine:* 20*l.* scholarship (given jointly by the House Committee and the Medical Council). Mr. George Earnest Herman and Mr. Tom Robinson, (Equal).—*Clinical Surgery:* 20*l.* scholarship (given jointly by the House Committee and the Medical Council), Mr. Tom Robinson; honorary Certificate, Mr. C. W. Vickers.—*Clinical Obstetrics:* 20*l.* scholarship (given jointly by the House Committee and the Medical Council), Mr. Tom Robinson; honorary certificate, Mr. George Ernest Herman.—*Dressers' Prizes:* given by the House committee for zeal, efficiency, and knowledge of minor surgery, 15*l.* prizes, Mr. Alfred Kebbell, Mr. C. J. Stocker, Mr. Alfred Hill, 5*l.* prizes, Mr. Lewis Mackenzie, Mr. Albert Morton, Mr. Kelly White.—*Buxton Scholarships:* given this year by the Medical Council, for proficiency in the subjects required for the preliminary examinations, 30*l.* scholarship, Mr. F. E. Pocock, 20*l.* scholarship, Mr. C. J. Vallance.—*Osteology:* 20*l.* scholarship (given by the Medical Council), Mr. C. W. Drew; honorary certificate, Mr. H. T. Shapley.—*Anatomy, Physiology, Chemistry:* 25*l.* scholarship (given by the Medical Council), Mr. John Blunsom; honorary certificate, Mr. H. T. Shapley.—*Special Certificates of Honour Awarded to Medical Assistants:* for three months service, Mr. R. W. Parker, and Mr. H. C. Fox; for six month's service, Mr. G. E. Herman; or four month's service, Mr. H. W. Page; for three month's service, Mr. W. Ley, and Mr. Philip Thornton.

Dr. John Lloyd, F.R.C.S., has been appointed one of the Commission of the Peace for the city and borough of Bath.

Queen's College, Birmingham.—The session at this college was inaugurated on the 3rd inst., by a *conversazione* got up through the instrumentality of Dr. Balthazar Foster, more than 300 students, professors, visitors, and medical men of the neighbourhood being present as guests. We hear that it is intended to open the session every year in the same manner.

Cholera in the Crimea.—A dreadful epidemic of cholera at Kertch, is reported by Mr. Barrow, H.M. Consul there. The generality of the cases have been very severe, death ensuing for the most part, in twelve or fifteen hours. In an adjoining house two victims died in twelve hours, and another is now at the point of death. The total number of deaths up to Sept. 17th, was 141, and, the number of cases up to the same date 318, the recovery of twenty-three being doubtful according to last accounts.

Cholera in Cuba.—Fifty-three deaths are reported from cholera in Havannah on the 5th, and eighty on the 6th inst. By all accounts the disease is rampant.

Bequests to Hospitals.—The following are bequeathed by the late Sir G. Philip Lee, K.T., in his will proved under 180,000*l.* To the Victoria Hospital, Surrey County Hospital, King's College Hospital, London Fever Hospital, St. Mary's Hospital, St. Marks Hospital, and the Cancer Hospital, 1,000*l.* each. To the Weybridge Convalescent Hospital, Brompton Consumption Hospital, Middlesex Hospital, City Orthopædic Institution, and the Ormond street Hospital for Sick Children, 500*l.* each.

The will of Dr. John Wilson, Inspector-General of Hospitals, was proved under 16,000*l.*

Medical Club.—The annual general meeting was held on Wednesday last, Sir W. Fergusson, Bart., in the chair. After the ordinary business had been transacted, the question of removing the Club to new and larger premises was discussed, and Dr. Lory Marsh stated that he had obtained the refusal of the lease of the house in Pall Mall East, at present in the occupation of the Union Bank. The outlay required for purchase of lease, furniture, &c., is estimated at £5,000, and it is proposed that the sum should be advanced by the members in debentures of £25 each, bearing interest at 5 per cent., and secured by a conveyance of the lease, furniture, &c., to trustees. The present members would be continued upon the same terms as are now established in the Club—£5 5*s.* for town, and £3 3*s.* for country members; and any new members joining before 1st January next would be admitted on the same terms and the payment of the present entrance fee of £8 8*s.* After this year, the entrance fee is to be £10 10*s.*, and the annual subscription to be uniformly £5 5*s.* for all members at home. It is believed that, when once finally settled in a suitable and commodious building, the Club will rapidly develop into one of the best in town.

The Present Medical Staff of the Prussian Army.—The *Allg. Med. Centr. Zeit.* of Berlin (No. 76, 1870) gives the following figures:—One medical officer for every 500 men. Besides this there is a special body of surgeons intended for the sick and wounded in the field, which body is called the sanitary detachment. Every corps of the army is followed by twelve field hospitals, each completely organised for 200 patients, so that every corps is provided with the means of treating 2,400 wounded. Each corps has besides a reserve, composed of three surgeons and three assistant-surgeons. There are also 200 civil surgeons, who have volunteered their services, attached to the army; and most of the great medical and surgical authorities of Germany have been appointed inspectors and consulting officers to the army sanitary department. Altogether there are about 2,700 medical men in active service with the German host. We find, however, in another part of the same paper that the Secretary at War has decreed that all medical men, who have chosen to serve as militants, should leave the fighting portion of the army, and take up medical duties, thus showing that surgeons are not too numerous.

NOTICES TO CORRESPONDENTS.

Correspondents sending newspapers will please mark the paragraph or item of news to which they desire directing our attention.

Prolegomenon.—Don't ask us to print your letters. Solicit a friend to mediate between you. The contemporary you name is only too fond of printing and amusing its readers with these personal brawls, or professional misunderstandings. We consider you more sinned against than sinning. At most the grievance is trivial, and you retain the patient. Forget and forgive.

Grist.—*Gratia gretiam purit.* We shall not forget your kindness. The three new subscribers shall have the Press regularly. We are indebted to you for similar acts in that part.

J. B.—The fault must be at your post-office, enquire further.

Philalethes.—"The people of Calabria feed their hogs on pears," as Horace says, *verbum sap.* Consult a properly educated physician. We cannot prescribe.

Dr. S.—Our respected correspondent may believe us when we assert the book is a *farrago libelli.* The other is in the hands of one of our reviewers.

A Numine Lalus.—You remember Lord Mansfield, on seeing your motto on the carriage of a noted quack, translated it "God help the patient." Without the motto we accept your contribution however.

R.—The fee is usually a guinea, but depends on circumstances.

Medical Education.—We cannot recommend any particular hospital or school for your son. We refer you to our "Student's Number." The sooner he enters the better, as the Session is advancing.

Raven.—Your letter is not acceptable in its present form, which is libellous, please remodel it.

Dr. E. M.—We send the additional copies to the addresses you give.

Antrim.—Yes, Dr. McCormack of Belfast. He does credit to Ulster by his operative surgery and splendid hospital management at the Seat of War.

Magnus.—You shall receive a private note by the end of the week, when we have enquired further in the subject of so much professional importance.

J. L. T.—We received the paper, but could not find the article; you should mark the subject to which you desire directing our attention.

A Lady Authoress.—Thanks, your communication shall receive the attention which it merits. We shall be glad to hear again from you.

A Medical Student Poet.—We don't print verses. We admire, however, your spirited attempt. Read Locke and you will find the reply to your question which would be too long for reproducing here.

F.R.S.—We hear that there are several candidates for the Regius Professorship of Natural History in Edinburgh, vacant by the resignation of Professor Allman:—We may mention William N. McIntosh, M.D. Edin., F.L.S.; H. Alleyne Nicholson, M.D., D.Sc. Edin., F.R.S.E.; and Wyville Thomson, LL.D. St Andrew's, F.R.S. We believe we are correct in stating that there is no truth in the rumours that either Prof. Flower, of the Royal College of Surgeons, or Prof. E. Perceval Wright, of Dublin, is a candidate for the chair.

M.D.—For publication your communication must necessarily be condensed—brief and pithy.

Sporans.—The fee should be five guineas.

Benjamin M.—1. The salaries of the Dublin Poor-law Medical Officers have been raised £25 per annum, the Belfast Dispensary doctors must try again. 2. Chemists ought not to prescribe. 3. No.

The Lady Adelaide.—Upon sending us your address we shall confide to you the author's name.

J. M. M.—We sympathise with Mr. Macaulay and the cruel persecution of the Duke of Buccleuch; write to the Hon. and Rev. Mr. Marsham, the Duke's nephew.

C. W.—The "Mystery of Pain" is a small philosophical book, generally attributed to a distinguished member of our Profession.

Maria.—We have heard that several applications from ladies for admission to the London Medical Schools have been made this year. They have been declined. The fact is that none of our Schools have accommodation for separate classes.

To Contributors—Accepted Communications received:—

"On the Treatment of Delirium Tremens," by Dr. Ludwig Meyer, of Berlin, translated specially for the Medical Press, by Thomas Bookin, F.R.C.S., to which is appended a few practical observations by the Translator.

Clinical Memoranda.—"Subcutaneous Injection of Morphia (Continuation), by John W. Martin, M.D.

"Cases of Pyelitis," by J. C. Thorowgood, M.D.

Dr. Kinkead, "On a New Digestive."

Mr. Milton, "On Eczema."

Dr. Hayes, "Cases in Country Practice."

Dr. Clarke, "Injuries of the Spine."

Dr. Dolan, "Clinical Memoranda."

Dr. Dickson, "On Baby-farming."

Dr. B. Taylor, "Paper read at the Science Congress."

A SUGGESTION.

To the Editor of "The Medical Press and Circular."

Sir,—I read with interest the communication of Dr. Bolton, of Leicester, who calls a certain journal "a Speaking-trumpet." The Leicestershire sheep are the largest in England, as Dr. Bolton knows, twice as big as South Downs! Dr. Bolton should call a spade a spade, for he well knows as I do that the speaking trumpet is a *tin-whistle.*

I subscribe myself, Sir,

A Roasted Apple with the Core in.

NURSES FOR PRIVATE PATIENTS.

To the Editor of "The Medical Press and Circular."

Sir,—Engaged in country practice I have been for the past few days trying to get a trained nurse for a wealthy private patient, but my efforts have been futile, because I did not know where to write for one. I have experienced the same difficulty before. You would confer a great favour upon me by stating the address of the best institution. I see advertisements in your journal to supply almost every want but nurses, and it is to be regretted that such institutions, if there are any, do not advertise in a Medical Journal like yours (as few country practitioners can afford to take two) stating wages to be paid, &c., according to the nature of the duties to be performed. Midwifery nurses so much per week; fever nurses so much, &c., &c. Excuse my encroaching on your valuable space.

I remain, Sir, your obedient Servant,

An English Country Physician.

GOING TO FRANCE TO DRESS A MAN'S HAND.

To the Editor of "The Medical Press and Circular."

Sir.—I thought your article "Glitter" would have eclipsed the light and put the extinguisher on false moons. Going to France to dress a man's hand, to breakfast on black bread and eggs, dispense cigars, behold the *British Medical Journal* in the battle-field (to light the cigar with?) and rest the weary bones on a sofa, could'nt all this have been done nearer London? Do you not think, Sir, "Sportive Visit to the Seat of War" would be a better title than "Surgical Visit" is?

My qualified assistant here went for his holiday to France. He tells his stories much better than any I have yet read. Will you accept them if I get him to write an account specially for the dear old independent Medical Press—dear to the hearts of us all who do not belong to the genus butterfly. My assistant did some *really clever* things with his knife. He has become quite a hero since his return, and is victimised by the ladies accordingly. Will it be said of your London men as of my assistant that he went for the name of the things? I have not the *heart* to go and see the ruin of a country I admired in the noonday of its beauty.

Yours,

Liverpool, Oct. 15th, 1870. Delta.

VACANCIES.

Charing Cross Hospital.—Surgeon-Dentist. Honorary.

Royal Free Hospital, London.—Senior House-Surgeon, Honorary, with board and residence.

CASTLEBAR UNION—Saturday, Oct. 1.

DR. BEAUMONT'S SALARY.

Mr. Hughes, pursuant to notice, moved that the salary of Dr. Henry Beaumont, the newly appointed Medical Officer of Castlebar North Dispensary District be raised from £90 to £110 per annum.

Mr. O'Donel—I have great pleasure in seconding the motion.

Mr. Nally—Let us first see if he deserves it. Why was the situation not advertised at £110? The extent of his district has been lessened since his appointment.

Mr. O'Donel—I second it for the reason Mr. Nally mentions—the diminishing the area of his district in taking two of the best divisions in it from him, by which he loses the registration and vaccination fees, and all the private practice that is to be had; for, it is well known that Turlough is much better for private practice than all the rest of his district. I think it would be just as well for us to act on principle. I would just as soon vote for increase before I know whether or not he is deserving of it, as after. I do not know Dr. Beaumont, but I know the district, and I believe a medical man at £90 a year not paid. Medical men, as a rule, are badly paid. We will be acting fairly and considerately by raising the salaries of each of the medical men as they came on.

Mr. Nally asked if the salary of any of the other medical officers had been increased?

The Chairman—Dr. Walsh's.

Mr. Cannon—The case stands thus: A doctor comes down; his work is lessened; and his landlord serves a notice of motion to increase his salary before he takes charge of his district.

Mr. Nally—The landlord ought to be applauded. He is an example to the landlords of the country (laughter).

Mr. Cannon—With reference to Mr. O'Donel's argument, I am surprised that he did not put it forward at the time the doctor's salary was being fixed—he knew the district then as well as he does now. It is rather soon of Dr. Beaumont to seek for a rise.

Mr. O'Malley—I think it is unnecessary to say more, because we are not the Dispensary Committe, which is the proper tribunal, and not the Board, to deal with the matter. It was I who gave notice to have Dr. Knott's salary increased before the Dispensary Committe, and on the increase being granted, it was then approved of by the Board of Guardians. Now the Guardians might as well appoint the doctor as raise his salary; but they have no power to do either, because the Dispensary Committee is the authority appointed by Act of Parliament. The appointment of the medical officer is made by the Committee, his salary is regulated, and both must be confirmed by the Guardians and the Poor Law Commissioners.

Mr. O'Donel—No such thing. I am quite satisfied to hang the issue of the whole question on that.

Mr. O'Malley—Dr. Blackwell's salary was reduced by the Dispensary Committee of Balla, and then brought here for approbation of the Guardians. The Act sets out that the Committe of Management shall appoint from time to time, subject to approval, one or more medical officers, with such qualifications as the Commissioners shall determine, and with such salary as the Guardians, subject to the approval of the Commissioners, shall determine, meaning that the appointment, as well as the salary, is settled by the Committee, and then determined by the Guardians and the Commissioners.

Mr. Cannon—Uuless it meets with the approval of the Board you would not trouble the Commissioners with it.

Mr. O'Malley—Certainly not.

Mr. O'Donel asked the Clerk his opinion.

The Clerk—With reference to that, Dr. Roughan was here within the last fortnight, and he asked me was there a notice given by a guardian to increase Dr. Walsh's salary. I said it had been given at the Dispensary. He said the Dispensary Committee had no power but to recommend: that it rested altogether with the guardians to reduce or increase the salaries of the medical officers.

Mr. Nally said the guardians should have been properly notified that the question was to be considered to-day. For his part, the only intimation he received of it was through the press. That he knew another guardian also who got no notice.

The Clerk—I sent it to you, Mr. Nally, and to every other guardian as well.

Mr. Nally—I did not receive it, and I get my letters regularly.

Mr. O'Malley again called attention to their treatment of the Dispensary Committee—that it was being thrown over board altogether.

Mr. Browne—I am very sorry to differ from you in your interpretation of the Act. The way in which I read it is this, that the Committee of management of the Dispensary investigate into the qualifications of the doctor, but the fixing of the salary belongs to the Board, because in the Act it says, "and with such salary as the guardians, with the approval of the Commisioners, shall determine." If there be any doubt upon the matter, the simplest way is to postpone the consideration of this motion to next Board day, and in the meantime obtain the opinion of the Commissioners. As regards the question of affording medical relief I look on it to be totally distinct from pounds, shillings and pence considerations, as entirely concerning the lives and health and wealth of her Majesty's subjects in the district, and no matter how high it may cause the rates to become, I conceive it is our duty to get the best medical man it is possible to obtain, and give such a salary as will bring an educated, well-qualified man to take charge of those people. You all know what I am going to say cannot apply to this country, as I am only a short time amongst you. I have seen the poor neglected, lives lost, and a great deal of cruelty resulting from too great a regard for pounds, shillings and pence. Guardians of the poor ought to be obliged by law to employ properly qualified doctors. You cannot expect £90 a year to be adequate remuneration. He must keep a

horse which will cost 10s. a week, amounting to £25 a year. When appointing a properly qualified man to the district, it is but right that we should give him a fair salary. Now, the doctor in Balla came here on a salary of £120.

The Chairman—£110.

Mr. Nally—£85.

The Clerk, on referring to a book, stated that Dr. Blackwell was appointed Medical Officer of Balla Dispensary District at £110 per annum, on 2nd July, 1863.

Mr. Cannon—At the time of his appointment a dépôt was established in Ballintubber, and that having been since taken from him, it was deemed right to reduce his salary likewise.

Mr. Browne—You must bear in mind that when you bring a medical man here you deprive him of every chance of medical advancement that he would have by going anywhere else.

Mr. Cannon—He would agree with a great deal of what Mr. Browne has said ; but his advice comes too late. Before advertisement issued all this should have been done.

The Chairman—I think we are all entirely too early.

Mr. O'Malley—Let the motion go on now, and the Commissioners will decide whether we are regular or not.

Mr. Nally seconded Mr. O'Malley.

Mr. O'Donnel proposed that the motion be postponed in order to receive the Commissioners' opinion on the Guardians' ability to raise the medical officer's salary.

A poll having been taken, there voted—For postponement, 6 ; against, 4.

Pending the Commissioners' decision, it was agreed to adjourn the further consideration of the notice of motion for a fortnight.

MITCHELSTOWN BOARD OF GUARDIANS.

THE KILDORRERY DISPENSARY QUESTION.

Mr. Therry—This day fortnight a wish was expressed at this board that the Rev. Mr. Riordan should endeavour to ascertain the feeling of the inhabitants of the Kildorrery Dispensary district towards their medical officer. The result is the petition I now hold in my hand, which bears 890 signatures of poor people, expressing their want of confidence in that officer. No pressure by solicitation, threat or otherwise was resorted to by the Rev. Mr. Riordan to obtain these names. I was not present on the occasion when these people were invited to pronounce their sentiments, but from all I can learn, from persons who attended, nothing could be more fairly or impartially conducted than the proceedings. Mr. Riordan told his congregation distinctly that they could express their confidence, or want of it, according as they felt, while, if they preferred it, they were at liberty to withdraw from declaring themselves one way or other. Mr. Therry read the petition as follows :—

To the Chairman and Guardians of the Mitchelstown Union County Cork.—Gentlemen,—We, the undersigned inhabitants, entitled by the Medical Charities Act to Dispensary relief in the Kildorrery district of your Union, beg respectfully to draw your attention to our grievances in our relations with your present medical officer. From the evidence of late investigation at Kildorrery, conducted by Mr. O'Brien, Poor-law Inspector, published in *Cork Examiner* and *Constitution* newspapers, as well as from the general testimony of dispensary patients and from our own painful experience, we are fully satisfied that the treatment of your medical officer has been so unsatisfactory for some years past as to cause your petitioners very serious anxiety regarding his immediate unconditional resignation for this district, or his absolute removal by the Commissioners as a Poor-law officer. We pray that after giving this memorial the benefit of your thoughtful consideration, that you will have it duly recorded on your Board minutes, to be transmitted for like purpose to the Poor-law Commissioners, and your memorialists will ever pray.

[Here follow 890 Signatures.]

Mr. Hennessy—That is strong enough, certainly—there can be no doubt about its meaning.

Mr. Therry—As Poor-law Guardian of that district, I have reasons to believe that the statements set forth in the memorial are perfectly correct (hear, hear).

Mr. Bailey would like to know what means were resorted to for the purpose of getting the petition signed, whether the names appended were all those of persons present at the chapel on the occasion, and whether people were not sent for to sign it, but did so voluntarily.

Mr. Therry—Let Father Riordan explain himself, and you will be satisfied that no undue influence has been used.

Rev. Mr. Riordan said, in accordance with the wish of the Board, expressed at its last meeting, he had drawn the attention of the parishoners to the subject of their treatment of Doctor Rogers for the few years previous, stating that he wished them to declare whether they deemed such treatment satisfactory or the reverse. He told them a difference of opinion existed among the members of the Dispensary Committee on the question, and that he was now anxious to know the opinion of people whose relations with the doctor were direct, and who might be reasonably supposed to know more than any member or members of of the committee. He told them also he had no feeling in the matter except to find what their opinion was, and to convey it to the Board of Guardians, and subsequently to the Commissioners. He stated, further, that there should be no pressure whatever put on them ; that they were at perfect liberty to express their satisfaction or dissatisfaction with him, as they thought proper. Having put the matter in the fairest manner—a guardian of the Board being present on each occasion—he found the result to be something over six hundred names furnished to the memorial from within the parish, the balance of the 890 names being from portions of the Dispensary district outside the parish. Nobody was to sign that memorial who was not sixteen years of age and upwards, thereby giving Dr. Rogers the fullest fair play. That was the course of election he had taken, and he could defy any contradiction, at that Board or elsewhere, as to the truth of the statement he now offered in reference to it (hear, hear).

Mr. Bailey said he had heard something about two little boys being sent round to a potatoe garden in his neighbourhood, and of signatures having been got of men from Kerry, Kinsale, Bantry, and other places. Were the 600 names signed in the chapel ?

Father Riordan said six hundred names were signed in the chapel. There was no ground whatever for any such statement as that which Mr. Bailey alleged had been made.

The chairman and other guardians while allowing that Mr. Bailey's inquiry was perfectly legitimate, and that such a course, if adopted, towards the Doctor would be totally unjustifiable, were satisfied that nothing of the was attempted.

Mr. James Hennessy—I have been hearing this long time the character the people gave of the Doctor. I heard them often say it was a terror to have to go near him. It is a terrible responsibility for any person that would try to keep him if he is not fit for his place.

Mr. Bailey—I have every confidence in him as a medical man.

Mr. Therry proposed, Mr. Magner seconded, and it was resolved (Mr. Bailey dissenting) that the petition from the Kildorrery Dispensary District, presented by the Rev. Mr. Riordan, C.C., bearing 890 signatures of persons entitled to medical relief under the Medical Charities Act, and which is, in our opinion, a faithful expression of their feelings of confidence, with respect to the medical officer of their district, be forwarded by the clerk for the consideration of the Commissioners.

In the foregoing proceedings is embodied the first open and avowed attempt to make the office of Poor-law Medical Officer subservient to religious influences, and we trust

that the Commissioners will have the courage to treat the proceeding as it deserves, and put the petition behind their office fire. Dr. Rogers has been already tried on charges raked up against him by the author of this petition from year to year, and he has been acquitted. He cannot, therefore, again be put upon his trial, and no re-opening of the question ought to be permitted. As for the petition, we would observe, that signatures obtained by such influences, from no one knows who, are only the blotting of good paper. If Dr. Rogers were the most exemplary of officers, and humane of men, the same pressure would secure the same result; and the Commissioners need not, therefore, hesitate in entirely disregarding it.

COOLRAIN DISPENSARY DISTRICT.

TO THE EDITOR OF THE "LEINSTER EXPRESS."

SIR,—Allow me, through the medium af your influential journal, as an individual dispensary medical officer, to express my feeling of sincere gratitude to Mr. Cullen for the very strong case he has made out for the dispensary medical officers of Ireland in his elaborate statistics in your last issue. He has proved to the most superficial mind that they are a most efficient and underpaid body. Mr. Cullen has stated in his letter that there were 775,327 dispensary and visiting tickets issued during last year. Now, Mr. Editor, that speaks volumes. How many of those 775,327 persons who got tickets may not have been fathers or mothers of families (which in Ireland are proverbially large), who, on falling sick, would have been incapacitated from supporting their families, and thus throw a heavy burden on the ratepayers, but for the timely assistance of the much despised dispensary medical officer? Or how many of them might have been valuable farm servants, whose labour their master could not afford to lose during a lengthened illness which might have been warded off by timely medical aid? The farmer well knows in these days of short help that the doctor is a valuable ally.

Mr. Cullen has found out by calculation that the rate of remuneration for each ticket attended is 2s. 1d! How munificent! Such unparalleled liberality! Can Mr. Cullen forget that a great number of the visiting tickets in rural districts represent thirty, fifty, hundred miles, or even more, travelled often in the night, or through rain or snow, to visit all kinds of contagious diseases, of which numbers of the laity are more afraid than of a mad dog? Mr. Cullen seems to writhe under the accusation of running the risk of endangering the efficiency of the staff in his solicitude to save the rates. Now I will ask any impartial man could any gentleman keep a horse and servant and himself, and pay rent, on £60 per annum! If not, he will have to dispense with the horse and servant, and then will he be able to discharge his duty efficiently? I have tried it in my district and found it impracticable. The fact of so few tickets being registered in the Coolrain district proves that sanitary arrangements are attended to, and the extension of disease prevented. I am sure that Mr. Cullen does not intend to insinuate that, in order for a medical officer to have his salary raised, he should make the poor sick. His duty is to keep them well as far as in his power lies. Mr. Cullen further states that the Poor-law Commissioners, guided by thirty years' experience, sanctioned only £60 per annum for the Coolrain doctor, but he seems to forget that the expense of living has increased very materially since that time.—I remain, Sir, your obedient servant,

HENRY R. RUCKLEY, L.R.C.S.I., &c.

P.S.—I hope the medical officer, whose salary Mr. Cullen states to be £5 11s. 4d., has good air in his district, as some gentlemen seem to think a man can live on that pabulum.

TO THE EDITOR OF THE LEINSTER EXPRESS.

SIR,—In your impresssion of the 1st inst., Mr. Cullen, P.L.G., writes in reference to the subject of the proposed increase, to the medical officer of the Coolrain dispensary district, Mountmelick union, and labours to prove that he and his followers on that board were justified in opposing an increase to his salary, mainly because he already received an income as high, and higher in some few instances, than other dispensary medical officers in Ireland (*the special circumstances however of such cases he carefully suppresses*); but Mr. Cullen must first prove "that two wrongs make a right" before he can lead men of enlarged or equitable disinterested views of economy to side with him. His premises are false, his conclusion consequently false, and his views narrow minded. He sets himself up as a champion for the rate-payers, and he supposes reduction of rates is almost the only duty of the guardians of the poor; but I am certain if the ratepayers, even of the division he represents, were fairly canvassed on the subject he writes upon, they would not endorse his niggarly sentiments; and I am equally certain the ratepayers of the Coolrain dispensary district, who have to pay an increase of salary to their medical officer, would cheerfully endorse the recommendation of the local committee and guardians for it; and I do trust also that should the case be fairly and forcibly put again before the Mountmelick board of guardians, there are members enough on that board who will be impelled by a sense of justice to support the Coolrain dispensary committee and guardians in their desire to fairly remunerate their medical officer. I maintain of all the districts in the union Coolrain is the one most requiring a liberal scale of remuneration, because all the doctors located in other districts have large towns or wealthier populations, consequently a larger field to supplement their dispensary salary by private practice. Coolrain district being very mountainous, entails on its medical officer several disadvantages, viz.: the visiting tickets he receives are mostly from parties scattered at considerable distances from Coolrain village over a wide mountain range very inaccessible, and entailing on the doctor the unavoidable expense of the purchase and keep of a horse, vehicle, harness, &c. His chances of private practice are *very small*, therefore he has mainly to depend on his salary as dispensary medical officer for the support of himself, his wife, and children. His case stands somewhat thus at present:—

Salary		£90 0 0	per annum.
House rent and taxes	£25 0 0		do.
Keep of horse, &c.	30 0 0		do.
	——	55 0 0	
Balance left of salary		£35 0 0	

From which he has to provide the necessaries of life, food, clothing, &c. He has also to sink for the time being in purchase of horse, vehicle, harness, and in the furniture of his house, and he his expected to maintain his position as a professional gentleman on such scanty and totally insufficient means—which I maintain no properly educated professional man ought to be expected to struggle to survive upon. I believe, however, the time is not far distant when the ratepayers, the guardians, and the Commissioners will find it is false economy to attempt to degrade the members of an educated, enlightened, and noble profession by treating its members as Mr. Cullen would fain do, viz., not better than second class artisans, and think the law will provide an adequate minimum salary for every poor-law medical officer.

The dispensary medical officers of Mountmelick Union I believe to be an independent body of gentlemen, and not without influence; and I call on them in the name of their Profession to rally round their brother, and use to the utmost their influence to support the laudable exertions of the Coolrain Dispensary Committee and Guardians in their desire to see simple justice done to their medical officer.—Your obedient servant, MEDICUS.

P.S.—Not being a Poor-law medical officer, I feel myself free to express my opinions.

Correspondence.

THE EXAMINATION OF PROSTITUTES.

TO THE EDITOR OF THE IRISH MEDICAL ASSOCIATION JOURNAL.

SIR,—I find it stated at the Social Science Congress, that Mr. Dalrymple, M.P. for Bath, had witnessed the examination of 300 Algerian women in company with several French generals. It will be doubtless interesting to your readers to learn how far such a disgusting, indecent, and brutalising exhibition of poor Arab girls, herded like cattle in the interests of debauchery and instrumentally violated in turn, in the presence of a number of men, has served its avowed end in checking disease. If you will allow me I will therefore quote a few lines from an article in the *Medical Times and Gazette* of Sept. 24th, 1870, in which the returns of venereal disease in the French Army are given. The article in question states that in Algeria the increase of venereal disease has been of a progressive character, and has been doubled since 1862. In 1865 there were 70 per thousand of effective strength suffering from venereal diseases ; in 1866 there were 86 per 1,000 ; in 1867 there were 145 per 1,000 ; in 1868, 309 per 1,000. Of 1,000 sick treated a l'hopital, 179 suffered from venereal diseases ; that is, more than one-sixth of the total number. The number of men non-effective from veneral diseases was equivalent to the loss of the entire army for 3·2 days, and of the men actually present 3·6 days, and each case was on an average thirty days under treatment. The utter failure of the filthy perquisitions of suspected women practised by the French administration is thus demonstrated. The folly of inspecting women for the benefit of soldiers as well as the inefficiency of the inspections of soldiers themselves as at present carried out in the French army, is proved by the fact that the increase was due in a great measure to an influx of fresh troops, and the editor of the *Medical Times and Gazette* very pertinently remarks, "we recognise in the spread of disease, in spite of preventive measures, one of the strongest proofs of the inefficiency of measures of repression under circumstances naturally favourable to the development and spread of venereal disease. In Rome there are no Contagious Diseases Acts, all such measures being very properly denounced by the Papal See ; and I would call your readers' earnest attention to the fact that the amount of venereal disease among the French troops quartered there is actually less than at any other station. Thus we find the relative proportions of venereal patients to the effective strength, and to total sick treated, were, in 1865, 81 and 85 ; 1866, 131 and 54; 1867, 73 and 26 ; and 1868, 20 and 9.

Mr. Donald Dalrymple has studied the working of these infamous laws to little purpose, if he has not learned that they are as futile in a sanitary point of view as they are obscenely cruel and hideously unjust.—I am, Sir, your obedient servant,

A SURGEON OF THIRTY YEARS' PRACTICAL
Oct. 15, 1870. EXPERIENCE.

Cinchona Cultivation.—The cinchona trees are taking well in Jamaica. *Nature* says that experiments on the culture of American tobacco in India are being made by the Maharajah of Burchwan in Midnapore and Cuttack. The last year's experiments with seeds from James River, Virginia, were very successful. The same journal informs us that the Cinchona cultivation has so well succeeded in the English hill settlement at Darjeeling, in the Himalayas, that last year 5,000 lbs. of bark were sent to London from Cinchona trees planted in 1862 on one plantation. Tea produced, in 1869, 1,319,743 lbs. from 10,769 acres of hill land formerly said and reputed to be worthless, and unsuited to give a return to Englishmen. We shall now hear of Indian bark as well as Peruvian, as we know Indian tea to hold its own against Chinese.

Baby Farming.—At a preliminary meeting held on Friday last, it was resolved to establish a society, to be called the "Infant Life Protection Society," having for its first object the introduction of a Bill into Parliament for the registration and supervision of nurses who receive children of others into their homes, and of the children entrusted to their care. The next meeting of this new society will be held on Tuesday, November 1st, at 3 p.m., at the rooms of the "National Association for the Promotion of Social Science," 1 Adam street, Adelphi, and all those interested in the subject are invited to attend.

Romford Sewage.—On Saturday a deputation from the Metropolitan Board of Works, accompanied by a number of scientific men, paid a visit to the farm of Mr. W. Hope, at Hornchurch, near Romford, in Essex, to witness his method of applying sewage to the cultivation of the crops.

The Preservation of Meat.—The subject for discussion at the Metropolitan Association of Medical Officers of Health last Saturday night, was the preservation of meat. Specimens of home and colonial manufacture were placed upon the table and examined by many present with much interest.

Testimonial to Dr. Dudfield.—We have much pleasure in announcing that a subscription has been entered upon in order to present Dr. Dudfield with a testimonial on his resigning the office of Hon. Secretary to the Poor-law Medical Officer's Association, which office he has discharged for four years, with the greatest zeal, tact, and ability, and thus contributed in no small degree to the success of the association. Mr. Benson Baker, 42 Grove Road, Regents Park, N.W., has consented to be treasurer to the "Dudfield Testimonial Committee," and will receive subscriptions. The labours of Dr. Dudfield in the cause of Poor-law Reform, have been very great—perhaps greater than those of anyone living, and we are glad that his modest work is about to be recognised.

Cambridge University.—The following appointments were made in the Medical Department, on Thursday last "That on the nomination of the Board of Medical Studies, C. Trotter, M.A., of Trinity College ; and T. W. Danby, M.A., of Downing College, be appointed Examiners for the first M.B. Examination during the ensuing year. That W. H. Drosier, M.D., and Mr. John Wood, F.R.C.S., be appointed Examiners for the second M.B. Examination during the ensuing year. That G. E. Paget, M.D., and E. Liveing, M.D., be appointed Examiners for the third M.B. Examination during the ensuing year. That Mr. Savory, F.R.S and F.R.C.S., and C. Lestourgeon, M.A., F.R.C.S., of Trinity College, be appointed Examiners for the degree of Masters in Surgery during the ensuing year. That A. W. B. W. Barclay, M.D. be appointed Assessor to the Regius Professor of Physic during the ensuing year."

Insurance against Accidents.—A new company has just been started, called The Carriage Accident Insurance Company, Limited, at St. Michael's House, Cornhill, for the purpose of granting insurances against accidents to carriages and all private vehicles against damage caused by accident of every description. As the number of accidents occuring daily is very considerable in all large towns, doubtless many of our readers will think it worth while to cover the risk against their brougham, by means of this new phase of insurance.

MISTAKEN ECONOMY IN THE FRENCH MEDICAL SERVICE.—The next great evil complained of is the mistaken economy used towards the Medical Service. The deficiency of officers is severely felt. The whole Corps de Santé numbered only 1,053, in 1868, for a strength of about 500,000. In the Crimean war, in May 1855, there was only 78 Medical Officers attached to the field and rear hospitals, for a force of 108,000 men ; or ·72 per 1,000 of strength, In the Italian war, the number was ·82 per 1,000. In the hospitals at Constantinople, each French surgeon had to attend about 300 patients daily ; while the English had to attend each only about a third of that number. It is during war that this want becomes so deplorable ; as in our short but bloody modern wars, as many as 10,000 to 20,000 men may be brought into the hospitals in a few days.

ON BABY-FARMING.*

By Thompson Dickson, M.A., M.B. Cantab.

In entering upon the subject of baby-farming this evening, I feel that no apology is needed for its introduction. Marvellous as the fact is, we live on in a sort of apathy, and though revolting dramas may be playing under our very eyes, we heed not the performance until some enormous catastrophe startles us out of our reverie. Even then too often we again relapse speedily into indifferentism, resume our enervate habit of seeing and not observing, and perhaps continue for ever afterwards in a sort of happy somnolence, forgetful altogether that the scene has been acted at all, still less acted upon the stage of daily life; and unless a second catastrophe should again rouse us to consciousness, we rather prefer the repose of oblivion. Even after many warnings it is rare for us, without a crowning disaster, to take action, or to attempt the enaction of laws which may sweep abominations out of the arena of our social systems altogether.

This representation indicates exactly our position in regard to the subject we are about to review; and, though we are perfectly cognisant of the fact, yet our minds seem closed to the truth that we are living in an age in which the mother has forgotten her sucking child, and has ceased to compassionate the son of her womb. She has abandoned her offspring to the mercy of the stranger, and the little ones have become the prey of worse than vampires.

When Gulliver described the baby-farming of Lilliput, he could hardly have imagined that such a business existed in England. The farms of the ideal Lilliputians were regulated by excellent laws; it is a pity that the actual farms of our own country are not under as good an administration.

We seem to have forgotten the case of Charlotte Windsor, and the story told by the child Harold McDonald of his foster-mother, Jagger, and her "Dop o' din in a dottle." We seem also to have forgotten the scathing articles in which the *Pall Mall Gazette* contrasted the highly moral tone of precept and the demoralizing tendency of the practice of some of our daily newspapers, which lent their advertising columns to proprietors of apartments furnished for ladies, with piano on drawing-room floor, nurse recommended by physicians, baby linen and other requisites found—others with all medical attendance provided, and some even with the audacious announcement that the child can be either nursed or adopted.

At the time that an old "hag" made some incautious statements to the Commissioners appointed by the managers of the *British Medical Journal* to institute inquiries, general attention was aroused. A knowledge of the fact that a deeply-rooted evil was living and growing like a vigorous upas in our midst spread, and a general outcry was raised, to be, alas! but too soon hushed by whispers that fed the fire and supported the life of the system; and unless society had been convulsed, and that nondescript something, the appendage of polite society called morality, had been shaken to its very foundations by the horrible revelations of the Brixton case the practices of baby-farming and baby-murder might have gone on undisturbed. Even the Brixton case has already become history, and there is a danger lest we become careless of the fact that a systematized traffic in infant life is going on.

* Read before the Dialectical Society.

The subject, however, is still in every one's mind, and the necessity of legislation generally felt; and if we can but now fan the smouldering embers into a flame, we may succeed in initiating a better condition of things.

Although there can be no doubt that there are numbers of women after the type of "the old original," "the jokelar person," who "says funny things and cheers 'em up," whose houses are but charnel-houses, and whose doorways but the mouths of the sepulchres, ever open to engulf the helpless dependent and confiding nursling; women whose profession is more properly defined as that of the murderer than the nurse; yet there is another side to the picture, and it is not impossible that in some lights parts of that picture may even appear beautiful. Regard, for instance, the foster-mother of the helpless infant orphan whom she fondles with tenderest solicitude and care; she is nevertheless a baby-farmer. Such baby-farmers often cultivate their charges with earnest devotion, and conscientiously fulfil the duty which it has fallen to their share to perform. Among these, however, there is often heartless neglect, avarice and love of gain being too often the incentive to pitiless deprivations and merciless cruelty. Again, we have another view of the picture in those nurseries in the manufacturing districts which are absolute necessities, and which go far to elevate baby-farming into the position of a self-made institution that cannot be pulled down, and therefore the more demanding that we should so deal with it that we may secure to each member of the commonwealth his due share of protection.

There is another class still, though one regarding which it is not easy to obtain statistical information. It happens, however, that among the upper grades of society, and from an endless variety of causes, a large number of children are put out to nurse. And since the nurselings are not free-will agents, but under the control of those deriving profit from their care, they seem at least entitled to state supervision.

Our subject naturally divides itself into two divisions, the one which is baby-farming in the strict sense of the term, the other that in which the term baby-farmer is but a synonym for baby-murderer.

In the five years 1863 to 1867, the Registrar-General recorded in England and Wales 578,394 deaths of infants under one year of life, and the majority of these only survived their birth a very short time. What proportion of these died from neglect, whether criminal or the result of absolutely uncontrollable circumstances it is impossible to say. Comparing the number with the total of living births of the same period, viz., 3,730,613, we have an average of 15·5 per cent. of infant deaths, which it has been estimated from the statistics of the Society of Friends, taking their returns as the nearest approach to a normal standard, that 11·1 per cent. would far more nearly represent the average infant death-rate under one year if criminality, ignorance, and carelessness be excluded. It is hardly necessary to show that the proportion of deaths of illegitimate children is vastly in excess of the legitimate.

Dr. Lankester, in his sixth annual report, says that he finds in his district that the inquests held upon illegitimate are equal to nearly a half of those upon legitimate children; and when it is remembered that only one child in seventeen is born illegitimate, it will be seen how large a proportion die under circumstances that demand an inquiry.

Mr. Acton, who has studied the subject with the greatest care, has given figures which correspond with those of Dr. Lankester. The former states that in the year 1867 there were 1,153 inquests upon illegitimate children, aged one year and under, against 2,960 inquests held upon legitimate children of like age, so that though the proportion of legitimate to illegitimate children exceeds 16 to 1, the number of inquests upon the former are a little more than double the number of those held upon the latter.

These figures, if they show nothing else, at least indicate that of the children who die under suspicious circumstances, the illegitimate bear to the legitimate a ratio of eight to one.

Dr. Tyler Smith, in a most able address on infanticide and excessive infant mortality, delivered in 1866 at the annual meeting of the Harveian Society, stated that in the year 1864, 47,440 illegitimate children were born in England, the total of births being 740,245, or a proportion of 6·4 per cent., and that the ratio of increase of illegitimate births to increase of population was as one-half to one-third.

It is not easy to arrive at a very accurate estimate of the death-rate of illegitimate children in England on account of the faulty registration. The returns show percentages of from 46 to 96; but judging from the returns of foundling institutions in France, in which the mortality percentages range from 60 to 90, we may conclude that 96 rather than 46 per cent. is nearer the average of our own death-rate; and Dr. Tyler Smith attributed to illegitimacy the cause of a large proportion of the infanticide which formed such a lamentable page in our national annals. And he remarked that the birth of what is called an illegitimate child is held to be a disgrace, especially to the mother. The responsibility of the maintenance of such a child is imperfectly defined; for the most part, if reared at all, it is reared in poverty, without participation in the ties and safeguards of home or family, and therefore it is not to be wondered at if illegitimates fail to reach maturity. From Dr. Tyler Smith's statistics domestic servants form the largest class among whom infanticide is practised, and the inducements of women of this class to conceal and destroy their offspring are certainly very great.

The workhouse treatment of unmarried mothers is tyrannical, and the women shrink from the union shelter; or if they avail themselves of it during their confinement, they are forced to take the infant away with them when they leave the big house. If a mother succeeds in getting an engagement as a wet nurse, her infant must be placed under the care of a dry nurse, when from want of natural food, inexperience, and improper management on the part of the nurse, and often, too, from neglect, it usually dies. The humber of infants brought to the workhouse as foundlings mostly all die also.

In London a large number of perfectly respectable and honest persons endeavour to add to a scanty and precarious income by undertaking the charge of

"nurse-children," and not infrequently fulfil their duty with a careful attention amounting often even to tenderness. Nor would it be a happy day for London and many other parts of England should such a system be done away with. Numbers and numbers of children daily stand in need of foster parents, and the causes which give rise to this need are almost innumerable. Vast numbers are illegitimate, and the necessity imposed upon the mother of supporting entirely by her own exertions both herself and her child, renders imperative that demand for nurses and nurseries which we have seen has lately been made the cloak and cover for crime.

The constant demand in our manufacturing districts for female and child labour, and the too lamentable poverty produced by wretched customs, such as the "truck system," compelling women in those districts constantly to work, necessitates the consignment of all the babies and the children not fitted for factory employment to the care of nurses, who are, as a rule, old women who have passed the age of serviceable factory hands, and who during the day, and often during the night as well, take charge of a number, sometimes a large number, of children, the elder of whom assist in keeping the younger quiet.

The standard of morality among the factory hands is proverbially low, and great numbers of illegitimate children are born amongst them; but whether legitimate or illegitimate, the necessity of the mother to continue her service in the factory is almost equally the same, and the nurses or baby-farmers are in requisition alike for both classes of children.

The inducements to infanticide among the factory girls are not nearly so great as among domestic servants. The factory girl requires only the character of a skilful manipulator, and sometimes not even that, and as the child's labour will after a few years be productive, their first engagement being to assist the old woman to take care of the babies, some sort of effort is made to preserve their lives; but, notwithstanding this fact, great numbers die. Nor is it to be wondered at, when they are deprived, to a greater or less extent, of their natural food, while that administered to them is, as a rule, wholly, or almost wholly unfitted for them, added to which the practice of the administration of narcotics—usually Godfrey's cordial or laudanum—to the fractious, is continually followed, not with any mal-intent, but often with honesty of purpose, both nurse and mother being fully persuaded that these abominable poisons are harmless, the nurse using them in the day to lull noise, which would otherwise convert the nursery into a Babel, the mother giving the dose at night to ensure her own rest, so that she may be fitted for her work in the factory on the morrow.

There can be but little doubt that much might be done by manufacturers themselves, in mitigation of the evils that exist, could a little more of that spirit called Christianity but actuate them. By affording the mothers more time to feed their children, and teaching them that the cultivation of domestic comforts is the surest way of rendering their lives happy, their labours more profitable, and their earnings more sufficient. Not only would some of the worst results of the present state be saved, but manufacturers would themselves reap a benefit by reason of the universality of accuracy in their hands resulting from the general improvement to their tone.

I have certainly no sympathy for that inhuman class of women who are too selfish to bestow upon their offspring those maternal duties which nature has prescribed. It is beyond all question, however, that many women in the higher walks of life prefer the enjoyments and luxuries of society to the performance of their maternal duties, and therefore they hand over the care of their little ones to the hireling; for those nurses and nurslings will continue to be in demand, and for members of the same classes of society. Also, those disgraceful advertisements I have mentioned were intended.

Running from the highest to the lowest of the monied classes, a demand for nurses and nurseries will continue, and homes will still be open for the reception of infants, whose parents desire never to hear of them again, and who are ready to pay any compensation for the child's adoption. I believe it to be impossible for any law to wipe out this state of things altogether, and as this is just the case where the greatest inducements for criminality are combined, it is the condition imperatively demanding the recognition of the state.

Under present circumstances, we detect one case while the many are left alone; and, on account of the supineness of our Legislature, we allow thousands to suffer, comforting ourselves with the mental promise that we will punish the offenders if we find them out.

In 1866, the Harveian Society appointed a Committee to inquire into the subject of infanticide, and the materials collected by that Committee were most valuable. Their labours were supplemented by an investigation, undertaken for publishing in the *British Medical Journal*, and the result of these inquiries combined was, that on the 12th March, 1868, Mr. Van der Ryl asked the Secretary of State for the Home Department whether his attention had been called to the statements in the *British Medical Journal* concerning the criminal practices connected with the system of baby-farming in the Metropolis; and whether he intended to put the law in motion to suppress such practices; and whether he would lay upon the table all letters and documents relating to infanticide and illegitimate children received at the Home Office during the years 1866 and 1867. Mr. Gathorne Hardy replied that in respect to the second part of the question, he was informed that there were not in the office any documents such as those described. He had read the statements in the *British Medical Journal*, but his attention had not otherwise been called to them. He had no hesitation in saying that, if true, they reflected great disgrace on any nation in respect to which they were made. At the same time, he must observe that the offences charged were crimes within the law; and it was no part of the Home Secretary's duty to act the part of public prosecutor. The attention of the public had been directed to the subject since the publication of those articles; but it was obviously very difficult, if not impossible, to get evidence of the transactions described in the *British Medical Journal* which would be available in a Court of Justice.

Again, in July of the same year, the Earl of Shaftesbury asked the question of the President of the Privy Council, in the House of Lords, whether the attention of the Government had been directed to the system of baby-farming; and, if so, whether they intended to institute any inquiry into the subsubject. The Duke of Marlborough replied that the matter was rather one for police than sanitary investigation. Measures might be adopted for putting an end to so inhuman a practice either by registering the houses of persons taking these children to nurse, or by a system of licensing, combined with periodical inspection by properly qualified officers. Government would turn their attention to the question during the recess, and he hoped that they would be able to discover means which, embodied in a Bill, would obviate the dangerous abuses to which attention had been directed.

Before Parliament met again, however, a new Ministry occupied the Cabinet, and nothing more was heard of baby-farming until the famous Brixton case forced upon us once more the fact that the business flourished, and, under the cloak of the system, the grossest crimes might be committed. How widespread the evil is may be estimated from a perusal of a letter, signed "A. B.," published in the *Times* on the 14th of July last.

The present condition of our law, without doubt, is the reason of the existence of so many of our social troubles; and the disinclination on the part of our law-givers to admit any principle, which they term foreign to the spirit of British Jurisprudence, is exceedingly great. The actual condition of many of our laws permits the doing of wrong; and, like the law of the Spartans, considers no sin to be a sin until it is found out.

The sentence of death passed upon Margaret Waters will not act as a deterrent to others as might fondly have been hoped. Baby-farming and baby-murder will go on as heretofore, with one or two slight variations in the present system; the first will be that baby-farmers will raise their prices, having learnt by the late trials that they are running greater risks than they formerly imagined they did; they will demand such sums as they think will equipoise the risk. A parallel occurred in the instance when some of the most devoted of those "immaculate" bodies, the London Vestries, with a sort of laudable activity, attempted to sweep out prostitution by indicting the keepers, of what they termed "houses of ill-fame," for nuisances. The immediate consequence of which was to drive a number of the bawds into other houses, where they recommenced business at increased charges, while deficiencies in accommodation were made up by certain hotels which immediately became brothels.

The second effect of the sentence passed on Margaret Waters has already begun to show itself in the increase of infanticide. Unfortunate mothers are, and will be, unable to pay the advanced prices of the baby-farmers, and so will be themselves the murderers. We have good evidence of this from the fact that some days since Dr. Lankester held no less than four inquests upon infants in one day.

In his eloquent Inaugural Address to the members of the Social Science Congress, at Newcastle-upon-Tyne, the Duke of Northumberland, adverting to permissive legislation, characterized it as a species of legislation anything but desirable, indicating at once a want of conviction and courage on the part of the law-giver, and inviting neglect of the intentions of the Legislature in deference to local prejudices.

It is a questionable sort of legislation, at best, that allows harm that good may come of it; and to allow a gross evil to live and flourish, in its own grossness, in order that an occasional prosecution may crop up by reason of some advertising growth, is monstrous. The spirit of the English law is only to step in when actual harm is shown; but it is, to say the least, a very imperfect law. When one instance of cruelty to an infant sufferer is shown, thousands of innocents are undergoing the same sentence. There was a time when the lunatic community were regarded in very much the same light. If they became troublesome and burdensome to their friends, they were handed over to the care and tender mercies of strangers, by whom they were maltreated, until at last their cry was heard, and the Legislature recognized the necessity of asylums, and passed permissive laws legalising such institutions, but requiring that they should all be registered and under supervision; and also that every person detained as a lunatic should be registered and visited by commissioners appointed for the purpose. However imperfect the existing Lunacy laws may be, and I, for my own part, am convinced that they are highly defective, yet they have worked a vast amount of good, and have, at least, saved many thousands from the ruthless torture with which the aliens used to be visited,

If our Legislature were once for all to recognize the necessity for baby-farms—I will call them nurseries—and require that they should be licensed, granting a licence only to those who could show themselves, by their respectability, entitled thereto, and subjecting all such nurseries to more or less frequent visits from commissioners, invested with a sufficient amount of power to deal summarily with all abuses, we might supply a present need, and at the same time wipe out one of the greatest blots upon our boasted civilization.

It has been suggested that the establishment of more foundling hospitals would meet the difficulty, provided that in these institutions were embraced the principles of some of the French foundling institutions. But, surely, the evils of the French system are not counterbalanced by the good derived from its adoption, since it has been shown that the mortality in these hospitals, as I have already mentioned, is 90 per cent.

Dr. Tyler stated that hospitals on the plan of that of the Enfans Trouvés, of Paris, tend to encourage—

1. Illicit connexion.
2. An increase of illegitimate births.
3. The abandonment of illegitimate children by mothers who could afford to rear them.
4. The abandonment of children born in wedlock by parents not desirous of large families.

In the last century, some years after the establishment of the Foundling Hospital in Great Coram street, that charity was, on the responsibility of Parliament, thrown open to indiscriminate admission.

In the first year, the number received was 3,296 ; in the second, 4,085 ; in the third, 4,229 ; and during less than two months of the fourth year, 3,324 infants were admitted.

After this time the system of indiscriminate admission was abolished. But in the short period referred to no less than 14,934 infants were, in this Metropolis, cast upon the protection and charity of the public.

By the present mode of admission into the Foundling Hospital, mothers are requested to make personal application. The father of the child must be dead, unknown, or not to be found. The children are put out to nurse in colonies in the country, and a premium is given to the nurses for rearing them up to a certain age.

The system is a good one, but its value and success lies in the registration and supervision associated with it. And if what has been done by the Foundling Hospital on a small scale was carried out in principle universally and by the State—viz., in detail, a registration of all births, and a registration and supervision of all the women who took nurslings into their houses—especial attention being paid to the food upon which infants so placed are fed, and sufficient authority being exercised to ensure and enforce proper care and attention, we should soon have an end to the gross inhumanity which so shocks us that we almost shrink from reflecting upon it. I will mention one means by which baby murder may be lessened is by the breaking down of some of the unreasoning and stern verdicts of society. I hold it to be a disgrace to our civilization, and to our boasted Christianity, to point the finger of scorn upon the poor girl whose only fault, after all, perhaps, is that she is human, and that she was not constituted of such frigid stuff that she could congeal into stone, and resent the soft behests and imploring tones of perhaps a practised seducer ; the poor girls are not altogether bad, and that they should be outcast and despised for an error is, I repeat, a disgrace to our civilization and our boasted Christianity.

In suggesting the necessity of the concession of society, I am not propounding an impossible proposition. In the sister kingdom, Scotland, where illegitimacy is so common, that the number of such births registered in the year often exceeds the number of legitimate, there is neither the vituperation of society nor the hatred of the family brought to bear upon the girl. It is true that she is usually summoned to attend the kirk session, where she is admonished by the minister and elders, after which she returns to her home, and her offspring is brought up in the midst of her brothers and sisters as a member of the family. So common is this state of things that nobody is ever shocked at it. But to the best of my knowledge infanticide as a common practice in Scotland is unknown. A valuable provision of the Scotch law is the legitimation of all bastards by the marriage of the parents. But the most valuable provision of all afforded by the Scotch law is the facility of marriage. If the father of the child has made any promise of marriage to the girl, she can claim him as her husband, and the marriage stands as a legal marriage in all the Scotch courts of law. And in this is the salvation of thousands of girls. And so perfectly aware of the provisions of the law are all classes in Scotland, that the case rarely comes to trial. The youth accepts the fact that he has a wife, and without any further question causes the marriage to be registered.

I cannot but conceive that a similar facility in England, instead of revolutionizing society, would purge English society of that maudlin sentimentality which is the prolific parent of that concealment that fosters crime. It is true that we should, perhaps, bring about some strange mixtures in families, but any reflections which might result as a consequence would be cast upon the proper persons, or the male members of the community, who now, as a rule, escape and are held harmless, while upon the poor girl falls the scorn of the world, perhaps the remorse of conscience, and the crowning misery of the necessity of providing for herself and her infant under overwhelming disadvantages. Can it be wondered at that in the slough of despair the mother should be tempted sometimes to lay violent hands upon her child ?

And now, Sir, in conclusion, I must apologise for the shortcomings of this paper. I desire to lay no claim to any merit in the manner of dealing with the subject. I have endeavoured to touch upon as many points as possible, my object having been that of opening discussion, not closing it. The compilation of this paper has given me much pleasure. I thank you, ladies and gentlemen, for your kindness in listening to it ; and as out of a multitude of counsellors there is wisdom, I now hand over the matter to you, with one hope—viz., that out of your deliberations upon it may come some action which shall lead to a solid and a permanent good.

ON DISEASES OF THE SKIN.

By J. L. Milton,
Surgeon to St. John's Hospital.

Continued.

Eczema—*Definition.*—An eruption of low, flattened, red papules, generally very small, often assuming the form of a general congestion, as in pityriasis rubra, or of limited congestion, as in tinea circinata ; the papules sometimes few and scattered, at others numerous and confluent ; followed by death and shedding of the cuticle, infiltration of the cutis, discharge of serum, sometimes puriform, and formation of crusts. In some cases vesicles, ill-formed bullæ or pustules may complicate the disease, especially at the outset ; accompanied by great itching ; health generally somewhat disturbed.

Pathology.—Up to a very recent period, eczema was classed, with scarcely a dissenting voice, among the vesicular diseases.* When in a paper, read some years

* "It is characterized in its commencement by an eruption of very minute vesicles."—Rayer, "Diseases of the Skin," 1835, p. 282. "It is characterized by an eruption of numerous minute transparent vesicles." —Neligan, "Diseases of the Skin," 1852, p. 70. "An eruption of minute vesicles."—Copland, "Dictionary of Practical Medicine," Vol. I., p. 547. "An eruption of minute acuminated vesicles."—Good, "Study of Medicine," Vol V., p. 620. "An eruption of small vesicles." —Burgess, "Manual of Disorders of the Skin," 1854, p. 96. "Caractérisé par des vésicules ordinairement petites."—Cazenave et Schedel, "Abrégé pratique," 1838, p. 90. "Les vésicules sont la lesion elementaire habituelle de l'eczema."—Hardy, "Leçons sur les Maladies de la Peau," p. 3. "Charactérisé par le développement d'une éruption de vésicules."—Bazin, "Leçons théoriques et cliniques," 1860.

ago at the Medico-Chirurgical Society, I opposed this view not a single writer, so far as I could learn, with the exception of M. Devergie and Mr. Erasmus Wilson, had ever expressed a doubt as to the propriety of this arrangement, and even these two authors had not gone so far as to abandon the old classification. M. Devergie at this time seems to be struggling against the conviction forced on him by his own observations. In 1857, after saying* that "if eczema be a vesicular disease by virtue of its morbid element, *the development of the vesicles is only momentary*, and appears at the commencement of the attack simply to disappear again in a few hours;" he, in other respects leaves the classification where he found it. What M. Devergie really means by eczema being *vesicular by virtue of its morbid element*, I am quite at a loss to comprehend; but, as the fleeting nature of the vesicles is so fully acknowledged, we need scarcely be surprised to find him stating directly after, that *it is very rarely the physician can see them* (the vesicles), and that their covering is so thin *that they can only be made out by the reflection of sunlight (!)* a very difficult kind of vesicle, I should say, for anyone to find. Yet, a little further on, apparently mistrusting his own words, we find M. Devergie describing eczema as a punctiform, reddened state of the skin, discharging serum abundantly—a view which approximates much more closely to the real state of matters in this respect. Mr. Hunt, too, at the very time he was classifying eczema as a vesicular disease, got very near the true facts of the matter, in one instance at any rate. He says,† in speaking of the symptoms of a case of this affection, "the vesicular character was not distinctly seen, *the original eruption presenting rather the character of papulæ, containing no visible fluid.*"

In the discussion which followed the reading of the paper alluded to, the view I had taken up, namely, that eczema is really not a vesicular disease, was opposed very decidedly, and I need scarcely say that it would be opposed now by many writers. Hebra, McCall Anderson, and others, however, distinctly admit what I then contended for, viz., that the elementary lesion of eczema is not necessarily a vesicle; but, on the other hand, they go farther, and assert that it may be an erythema, a vesicle, a papule, or a pustule—a view which will, beyond all doubt, be ultimately adopted, but which, to my thinking, requires considerable modification.

This change of opinion seems, so far as I can make out, to be entirely attributed to the great influence exerted by Hebra. Not long ago, Dr. Hugenberger, in a paper published in the *St. Petersburgher Medicin Zeitschrift*, and of which a condensed account was given in the *Quarterly Journal of Cutaneous Medicine*,‡ treated the question as if no person but Hebra had ever touched upon the subject. But I believe Hebra first published his views on the nature of eczema in December, 1862, in the *Wiener Medizinische Wochenschrift;* whereas, the paper I speak of, in which eczema was defined as an inflammation of the skin, followed by death and throwing off of the cuticle and discharge of serum, and in which I expressly denied its vesicular nature and described pityriasis and tinea circinata as capable of passing into decided eczema, was read before the Medico-Chirurgical Society in 1860 and 1861, and a translation of it appeared as early as May 1861, or nearly a year and a half prior to the appearance of Hebra's first communication on the subject, in the very journal in which he first made known his views. I speak under correction—M. Hebra may have anticipated me, but I can only judge from those dates I have been able to obtain access to.

Mr. Erasmus Wilson recognizes six essential varieties of eczema:—1. The erythematous; 2. The papular; 3. The vesicular; 4. The ichorous; 5. The pustular; 6. The squamous. The arrangement seems to be essentially faulty. The erythematous is simply a variety of the papular form; the diffused redness arising from the coalescence of a mass of papulæ, is only a degree of the other, and is a different state altogether from genuine erythema. True eczema is not vesicular; the vesicle, as I hope to show, is an accident, a complication, as is the pustule, while the squamous and ichorous forms depend for their existence on conditions incident to the mature state—not the origin—of the complaint, and as such should have been separated at the very outset—unless, indeed, under squamous Mr. Wilson comprehends those cases in which a dry squamous state precedes, or even takes the place of, the watery stage, as for instance cases of eczema siccum of the hands, feet, and ankles.

Hebra* divides eczema into five kinds:—1. Eczema squamousum or pityriasis nigra—a complaint so rare in this country that I have not seen an instance of it in more than sixteen thousand cases of skin disease; 2. Eczema papulosum or lichen eczematodes; 3. Eczema vesiculosum or solare; 4. Eczema rubrum or madidans; 5. Eczema impetiginosum or impetiginoid eczema. He does not class eczema as a vesicular disease; but, on the contrary, ranges it with prurigo; he does not, however, reject the vesicular form, for he not only admits eczema solare, but says†—"While in one case the eruption of vesicles forms the starting point of the eczematous symptoms, we, in another case, see red scaly spots first of all." In other words, he recognizes the vesicle as a necessary lesion in one variety.

I cannot say that this arrangement is, to my thinking, satisfactory. The form of eczema which Hebra considers essentially vesicular, eczema solare, is simply a form of true herpes and totally distinct from eczema. He only allows forty-eight hours for the existence of the vesicles of acute eczema, whereas the true vesicle endures a much longer course; eczema solare, for instance, undoubtedly lasts beyond this time. Again, he maintains that eczema is still the same complaint, whether it appears under the form of vesicles or papules, and this view he upholds on the ground that an artificial eczema—as, for instance, one produced by rubbing in croton oil—will appear in the form of both papules and vesicles, according to the part it is rubbed into, a view which some writers have adopted without appearing to have examined it in any way. But with all possible deference I submit that it is faulty, for it is as certain as any fact can be that the papular form of eczema will appear on the very places where we at times see undoubted eruptions of vesicles; for I need scarcely say that both are occasionally found on nearly every part of the frame. It seems, therefore, clear that there must be a fundamental, essential difference between the process which brings forth the papule and that which generates the vesicle, and that difference in the eruption is not due merely to difference of site. There is another point on which I must also differ from Hebra. He looks upon the infiltration of the skin and the itching as "*the disease*," a view in which he is backed up by Dr. McCall Anderson, who seems‡ to have almost literally adopted his tenets. I consider the essential feature of eczema, the test of its nature, to be a chronic weeping surface, which I have never yet seen called into being by an eruption of true vesicles or pustules.

It simply requires that surgeons should judge for themselves to be convinced that true eczema is not vesicular at any period of its course. It was not without considerable diffidence that I first hazarded this statement, standing, as I then thought I stood, quite alone in this view. Having, however, suffered from this complaint, I had on numerous occasions watched the development of the morbid process hour by hour from the very beginning, and had long before satisfied myself that there was no real foundation for the view so generally entertained. Being unwilling, however, to rely exclusively on the evidence afforded by my own

case, I examined with a good lens a great many patients of all ages, and wrote down the observations just as they were made; but I looked in vain for the vesicles of eczema. I found, it is true, vesicles enough, but none which passed into a weeping surface. Again, on reading a paper in the *Medico-Chirurgical Review*, in which the old doctrine was upheld, I repeated these observations with all the care I could fancy necessary, but the result was the same, possibly the reader may say because I wished it to be so. Some circumstances were, however, noticed which probably contribute to support the view so generally taught.

(To be continued.)

CASES OF PYELITIS AND RENAL ABSCESS.

By John Thorowgood, M.D. Lond.,

Senior Assistant-Physician to the Hospital for Diseases of the Chest, Victoria Park.

Pyelitis, or inflammation of the pelvis of the kidney, when it has existed for some time, and is probably associated with some calculous formation in the kidney, is apt to lead to ulceration through the mucous membrane, and suppurative action being thus set up in the renal substance itself a true renal abscess forms, which may open in various ways, and gradually wear out and destroy the patient. This fatal result is illustrated in the two first of the following cases which have fallen under the author's notice. In the two second cases the pyelitis was simple, and the patients both seem to have done well, as no renal abscess seemed to form in either case.

Case I.—Miss H., æt. thirty-five, almost crippled with rheumatoid arthritis in the joints, was seen by me some years ago, and presented the following symptoms:—Face clear and flushed, is decidedly hysterical, and complains much of pain in region of sacrum. She has prolapse of the rectum, and a certain degree of uterine displacement makes micturition difficult and painful. With the urine is passed much pus, also from the bowels, the vagina, and by vomiting. She declares she has been in the habit of discharging pus in this way for some years, and various opinions have been given as to the source of these purulent discharges. She has cough and expectoration, but never had any hæmoptysis.

On examining the abdomen, attention is drawn to a prominence in the left hypochondrium. Passing round behind a flaccid bulging tumour is felt, which varies in size at different dates of observation.

I considered the case to be a cystic tumour of the left kidney, with abscess opening into stomach and intestine.

In four months she died of exhaustion and constant vomiting. The *post-mortem* examination, for the notes of which I am indebted to Dr. Dryland, showed some adhesions at base of left lung, and patches of tubercle also. In the apex of right lung, a small deposit of tubercle was found; heart healthy, liver much enlarged, extending over the left side; the colon lay between the ribs and the enlarged liver, a fact that explained the existence of a tympanitic space during life abruptly bounded by perfect dulness. In Dr. Ballard's book on the "Diagnosis of Diseases of the Abdomen," this occasional position of the colon is specially alluded to as important to bear in mind.

A very large cyst projected from the upper part of the left kidney, containing much pus. The ureter on this side, all the way down to the bladder, was as large as a finger, and full of pus. Bladder large and distended with purulent urine. The cyst communicated with the intestine, but not with the stomach, so far as could be made out. No calculi were found in bladder or kidney. The early history of this case was never clearly noted down, but the absence of calculi, and apparently of any distinct occlusion of the ureter is remarkable. The other kidney appears not to have presented anything remarkable.

Case II.—A gentleman, æt. thirty-nine, was brought to me by Dr. Lawrence, of Wandsworth, in November, 1868, in consequence of his frequently passing blood in his urine. The blood comes after the urine has passed, and it is now twelve months since it first appeared. There is no œdema; pulse 100; appetite bad; at times vomiting.

Lumbar pain, fulness and tenderness, exist on the right side; over the bladder there is very little tenderness.

The urine is acid; sp. g., 1,020, highly charged with very white albumen, and full of pus and blood corpuscles when seen by microscope.

The hæmorrhage was considered to be of renal origin, and the right kidney to be in a state of degeneration. For some time previous to death the urine was clear and free from pus.

In February this gentleman died. The *post mortem* examination was made by Mr. Bryant, who had also seen him during life, and the right kidney was found to be a sac full of pus, the ureter also full of pus and dilated to within one inch of its entry into the bladder, where it was impervious. The left kidney was healthy, but double its proper size; bladder also healthy.

There was no calculus found anywhere, but it seemed probable that the complete occlusion of the ureter did not take place till some short time before death, after which the urine that flowed must have come solely from the left kidney, and was, therefore, clear and healthy. This patient was always a free liver, and very intolerant of medical control. I only saw him once when he came to my house.

Case III.—A young man, who has been under my observation for nearly two years as a hospital patient has, for more than this period of time, observed his water from time to time to be very turbid with thick white matter. This thick matter abounds in albumen, and becomes very viscid when mixed with liquor potassæ. It contains abundance of pus corpuscles. Has passed blood, but not lately.

The right flank is full and tender, and when he first came under my observation this fulness and tenderness were very prominent symptoms.

The man has kept about on his feet, but did not feel able to attend to his duty in the militia, and now has lost almost entirely the tenderness in the flank; the fulness also is hardly perceptible, and the urine very much clearer. Attention to diet, abstinence from alcoholic drinks, and the persistent use of the tinct. ferri. perchlorid. have been the curative measures in this case.

During the time this patient was under my care, I read in the *British Medical Journal*, for June, 1869, Dr. Edward Mackey's "Reports on Cases of Pyelitis treated with the Tincture of Cantharides." I tried the tincture in plain water in my case, but did not observe any effects therefrom, either for better or worse.

When we find a patient passing quantities of renal pus in the urine, and complaining also of a large and tender swelling in one side, we certainly may consider the case as a rather serious one, and yet with all these ugly symptoms the patients not rarely get well, though they may still retain the remains of an indolent tumour in the side, as in the last of the above recorded cases.

When the case has become one of true renal abscess with suppuration in the substance of the kidney itself, I consider the prognosis bad, and in these cases there is at times found some calculous formation, which by its continued irritation, has led to the fatal suppuration by perforation

of the mucous membrane of the renal pelvis. As long as the case remains one of uncomplicated pyelitis, we may hope for recovery, even though the tumour be of some size, and the amount of pus discharged considerable.

CASE IV.—Was that of a woman, æt. fifty. For many years she had, from time to time, passed large quantities of pus in the urine, but rarely did she complain of much pain.

The right flank was tender on pressure and a very distinct tumour was perceptible there; during the four years in which I have observed this case, I have noted a gradual cessation of the purulent discharge, while at the same time the swelling has very greatly diminished, and now the woman considers herself quite well.

In this case, as well as in No. III., the patients were well able to walk about, and they were encouraged in this practice, as I believe it an important means of keeping the renal pelvis empty, and promoting the downward passage of its purulent contents. Very careful habits of life, and the persevering use of the tinctura ferri., were other means that decidedly promoted the cure.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. IX.

TREATMENT OF SEWAGE BY FILTRATION.

ATTEMPTS have frequently been made to purify sewage by means of rude processes of filtration and spontaneous precipitation, but they have never been successful unless the effluent sewage could be discharged at once into the sea, or into a tidal stream, for none but the grosser particles of suspended matter can be thus separated from sewage.

A *coarse filtration of sewage* is generally practised before it is distributed upon the land for irrigation. At Aldershot and Rugby, for example, the sewage is strained through perforated planks, with apertures of about three-quarters of an inch in diameter, but the purifying effect is not considerable, for the amount of suspended matter in the Aldershot sewage was only reduced from 43·77 grains per gallon to 35·01, the organic matter of which was 14·02 grains and 8·77 grains respectively. Even with a more elaborate system of filtration, as was lately practised at Merthyr Tydvil, where the sewage passed through a filter of course iron slag about three feet thick, and then through a small filter of coarse vegetable charcoal, the suspended matters were reduced from 169·81 grains per gallon to 32·31 grains, and the soluble matters were not at all affected. In this case the flow of sewage was about 915,000 gallons per day, from a district with a population of about 50,000 persons; and as the sewage flowed through a drain nearly four miles in length, the suspended matters were completely disintegrated before they arrived at the outfall at Troedyrhiew, where the sewage received a small quantity of caustic lime before it was passed through the filters of broken slag and charcoal. The slag filter was 219 feet long, 5 feet wide, and 3 feet deep, and the charcoal filter which succeeded it was 7 feet long, 3 feet wide, and 2 feet deep. Samples of the sewage were taken before it entered the filters and after it left them to be discharged into the River Taff, and the following are the results of the analysis :—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	47·27	33·07
Chloride of sodium . .	7·19	5·76
Organic matter . . .	11·23	6·94
Ammonia	2·240	1·582
Ditto organic . . .	0·159	0·161
Nitrogen as nitrates, &c. .	0·000	0·000
Oxygen required to oxydise	1·231	0·711
Matters in suspension . .	169·81	32·31
Organic matter . . .	72·64	14·11
Mineral ditto . . .	97·17	18·20

Mr. Strang, of Glasgow, has designed an apparatus for filtering the whole of the liquid matters discharged from a water-closet. It consists of a box about three feet long, eighteen inches broad, and four feet deep, having a filtering medium composed of the refuse coal ashes of the house, the filtration being upwards, so that the solid matters are retained in the lower part of the vessel, while the liquid portion passes away through the ashes. The apparatus may be placed in connection with the closet or the outfall drain from the house, and the solid matters can be removed from it when necessary. The apparatus has been tried at a public institution in Glasgow with about 200 inmates, and has, apparently, worked very well. Samples of the effluent water which we have examined have been very free from suspended matters, and Dr. Anderson reports of it that so far as deodorizing and decolourizing the fluids are concerned it is perfectly successful, although it allowed the soluble portions of the urine to escape untouched. The composition of the effluent liquid and the retained solids was as follows :—

Constituents per gallon.	Effluent liquid.	Retained solid.
	Grains.	Grains.
Total solid matter . .	13·20	1136·00
Organic matter . . .	3·12	269·92
Fixed salts . . .	10·08	166·08
Ammonia	0·19	59·81
Phosphoric acid . .	0·40	57·93

He reports that when the retained solids are mixed with about their own bulk of ashes, they form a solid compost, which is worth, as far as the ammonia, phosphoric acid, and alkaline salts are concerned, about 9½d. per ton, but that by an improvement of the apparatus a good deal of the superabundant water might be got rid of, so that the retained solids might be procured in a more concentrated state.

The late Mr. Austin, of the Local Government office, was of opinion that sewage might be purified by means of portable filters placed in the course of the sewers, each filter receiving the sewage of about 3,000 persons. In this manner the solid constituents of the sewage would be received into the filters and so retained before they had become disintegrated by the mechanical action of the stream, or by chemical decomposition; and when great

purity is required, he proposed that there should be a second, or even a third or fourth subsidiary moveable filter packed with broken clinkers, breeze, or gravel, and a layer of charcoal; and he enumerates the following as the advantages of this method, namely:—

"1st.—The filtration is easily accomplished, and the great r part of the fertilising ingredients are retained in the solid state in the manure box.

"2nd.—The solid sewage, confined in a portable vessel and surrounded by a deodorizing medium, can be taken from the drains in the course of a few minutes and conveyed without nuisance to the place destined to receive it.

"3rd.—The fluid part rendered innocuous may be allowed at once to escape into the nearest water-way, thus dispensing with the construction of large and costly conduits for its conveyance to distant outlets.'

As regards the profits of the system he considered that the solid manure would freely sell at the rate of 2s. per individual per annum, and that with 2s. 6d. per head per annum for the dust and refuse of a town, there would be a return of 4s. 6d. per head per annum; and allowing 3s. 3d. as the cost of expenses, &c., in working the system, it ought to yield a clear profit of 1s. 3d. per head of the population per annum, instead of the usual loss on interest of capital sunk in irrigation works. Experience, however, has shown that the filtration of sewage is not successful or satisfactory, and it has been invariably abandoned wherever it has been tried, as, for example, at Rugby and Birmingham, where sand filters were used, and at Chelmsford and Bilston, where clinkers and ashes were employed; for if the filtering material be fine in its texture it speedily clogs, and if it be coarse, it fails to remove other than the grosser particles of sewage.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

October 17, 1870.

John Gay, Esq., President, in the chair.

The President opened the Ninety-eighth Session with an Introductory Address "On the Limitations of Surgical Art." The speaker was listened to with much attention, and at the close of the address a vote of thanks, proposed by Mr. De Meric and seconded by Dr. Richardson, was unanimously accorded.

Dr. Andrew Clark then read the paper of the evening—

ON LOCAL INFLAMMATIONS IN CERTAIN DEFINED CONDITIONS AS CAUSES OF PULMONARY PHTHISIS.

The author said that hitherto his illustrations had been drawn from cases of pneumonia and pleurisy, and as yet he had found no exception to the laws he had set forth as regulating these relations to phthisis. In the present paper he proposed to take his examples from chronic bronchitis, which, though a less common, was an equally efficient agent in bringing about phthisical destruction of the lung.

Case 1.—A woman, forty-eight years of age, was admitted into the London Hospital for chronic bronchitis in June, 1866. She has had winter cough for twelve years back. Percussion sounds good over both lungs; with the stethoscope sibilant and sonorous râles are heard everywhere, and at bases there is coarse moist expectoration; pulse, 80; no fever or night sweats. She was treated with alkalies, and afterwards with acids, iron, and creasote inhalations, and was doing well until she was placed on a more liberal diet, with beer and wine. It being obvious that the change did harm the diet was reduced. This displeased her, and she left the hospital. In three months she was again admitted under another physician. She got worse, became feverish, and in February, 1867, dulness on percussion in the supra-spinous fossæ was noted. In March lung tissue was found in the expectoration, she got diarrhœa, and died in the following May. The *post-mortem* examination revealed extensive disease in the left lung, the bronchi were thickened and dilated, and the intervening lung tissue was converted into a dense fibrous mass; a few small cavities were seen, and also some grey tubercles in both apices.

Case 2.—J. L., aged sixty-five, a widow, had winter cough for ten years. On admission, had much cough and muco-purulent expectoration; no dulness on percussion; sibilant râles over both lungs; pulse, 64; temperature, 98. This patient gradually declined owing to a nervous shock; she got hæmoptysis and diarrhœa, and signs of consolidation about right lung. She died, but no *post-mortem* was obtained.

Case 3.—J. W., aged fifty-three, a dock labourer, had bronchitis over twenty years. Four years ago his strength failed, he got profuse purulent expectoration, he became feverish, bronchial breathings and crepitations were heard over his chest, and right lung became consolidated about two years later. The sputa became lumpy, and contained areolar of elastic tissue. In December, 1869, the urine was found to be albuminous, and in the following April he died. The *post-mortem* showed dilated tubes, grey tubercles, and small cavities in the lungs.

Case 4.—Mrs. B., aged sixty-one, lives in Kent, for many years subject to bronchitis. In 1864 general health failed; she became feverish, and bands of elastic tissue were found in the sputa; crepitation heard in middle-third of right lung. The progress of the disease here is slow. Pulse, 80; temperature, 98. The patient is still under observation.

In concluding, Dr. Clark said that the chief causes of phthisical complication, in cases of chronic bronchitis, appear to be repeated colds, over-feeding, and the abuse of stimulants. Loss of strength, feverishness afterwards subsiding, and coarse moist crepitations were signs of the phthisical condition. When the bronchi ulcerate, fibres of lung tissue are found in the sputa. Fibroid or tubercular pneumonic changes in the lung follow, but the progress of the disease is usually slow. By meeting feverish complications with rest, milk diet, and salines, and by the use of inhalations of iodine, creasote, or carbolic acid, and appropriate treatment of tonics and diet, the progress of the disease may be greatly retarded, and life indefinitely prolonged.

Dr. Symes Thompson agreed with Dr. Clark that tubercle was not often the primary mischief; these cases showed the value of early treatment to avert the phthisical complication.

Dr. Thorowgood said that in going over the patient record of the Victoria Park Hospital, he had noticed a large number of the cases of phthisis to have had their origin in a catarrh at some more or less distant date antecedently. This bronchitis was probably inefficiently treated, while doubtless alcoholic drinks were freely taken by the patient, till the lung breaking down he is obliged to become an in-patient of the hospital.

Dr. Hare said that we must not rush too hastily to the conclusion that the disease was of catarrhal origin. Hospital patients usually referred all their ailments to cold caught. He could not agree with Dr. Clark that a pneumonic deposit unabsorbed at the end of three months would never go. He had observed no case of pneumonia where the consolidation persisted for two years and then went quite away. He insisted much on the value of counter-irritation as a curative measure.

Dr. Semple complimented Dr. Clark on his accurate reports. He believed such cases to be very rare, and commonly the sequence of events was the very reverse of that stated. Early tubercle causes the bronchitis, not the bronchitis the tubercle.

Mr. Sheeler made some remarks on the importance of perfect ventilation as a preservative against phthisis.

Mr. Peter Marshall asked if Dr. Clark included the cases of acute phthisis in young persons as sequelæ of bronchitis.

Dr. Wiltshire inquired as to whether there might have been any heart disease leading to mechanical impediment of the circulation and hæmoptysis, which might have caused deduction of lung tissue.

Dr. Clark, in reply, said he must admit Dr. Hare's case of pneumonia to be an exception to the rule he had propounded. He quite agreed with Dr. Hare as to the value of counter-irritation. He did not include cases of acute phthisis in young children as sequelæ of bronchitis. He had no reason to think

that there was any mechanical obstruction of circulation likely to cause such hæmorrhagic destruction of lung as he had himself described in his lectures before the College of Physicians in 1866.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 26, 1870.

LIFE INSURANCE.—No. II.

The concurrent appearance of American Life Offices in the British market and the passing of Mr. Cave's Bill for the better regulation of English offices naturally suggest a closer attention to the comparative condition of the American and the British law and practice. After the scandalous facts which came to everybody's knowledge concerning certain English offices of high pretensions, it was evident to every eye that legislative interference for the protection of personal and family interests, largely involved in such companies, had become absolutely necessary and solemnly incumbent. Although the Act now in force for this end has most stringent regard to Associations which may be formed in future, yet it makes obligatory upon such as already existed, periodical statements of accounts placed before the authorities, the public at large, and the parties more interested especially, of such a nature as to constitute at all events some guarantee against the repetition of that wasteful, not to say fraudulent, trifling with the hard savings and the rightful expectations of the many, of which the revelations of the year of panic afforded abundant and sickening proof.

In considering the claims and merits of American offices, whether as confined to their own country or as proposing to transact business in ours, it must never be forgotten that they took the precedence of ours, and, in fact, set us the example of submitting their proceedings to the periodical inspection of public functionaries appointed for the purpose. In the several States where life insurance is carried on by offices established within their bounds, not only is it compulsory on those offices to report progress from time to time, but special commissioners are appointed to look after them, rigorously to examine the returns made, and officially to report and record the results of such examination. In the Empire State of New York, as in several other States, each Life Insurance Company is required by State law to make a deposit of equal to twenty thousand pounds sterling with the State in which it carries on business. The Companies are further called upon to produce sworn statements annually of their assets and liabilities, income and expenditure, in full detail.

It is the duty of the State Commissioner, with these facts before him, to form a valuation of each office, upon a basis prescribed by law, with a view to ascertaining for the information and guidance of all, the amount of the liability or the reserve under policies outstanding. This important functionary is likewise empowered to investigate for himself the affairs of any particular Company which may be under a suspicion of being in a condition of insolvency. If, after such investigation, he see just occasion for prompt action and decisive steps, he is authorised to arrest by legal process the course of the delinquent office, and prevent its management from continuing to do business.

Provided always that this important and responsible duty is confided to men properly qualified and of inflexible uprightness, the arrangements concerning it leave little or nothing to be desired. Evasion of the requirements can only be effected by the offices by false swearing, which would prove a very dangerous resort. Let tricks of this sort be reasonably suspected, and probing investigation would promptly follow; while detection would lead to instant conviction, and conviction to rigorous punishment. These are some of the grounds which Englishmen taking out policies in an American office would have for persuading themselves that the risk of insurance is far from being in proportion to the breadth of the Atlantic, but that, on the contrary, the straits of Dover joined to a country and people entirely foreign might make a great difference in point of security than that vast ocean joined to a country and people that, though politically foreign, are in law and language, morals and manners, our next of kin.

The State laws in several of the States would seem to give securities which may be admitted to be so far quite satisfactory and perhaps complete, and it only remains to form a general law for the whole commonwealth, based upon the same principles and adapted, on the widest scale, to fulfil the same useful and necessary ends. We take the liberty, therefore, of suggesting to the Government at Washington, through their respected representative at this Court, of establishing a National Bureau founded upon the practice of individual States, and resulting in the formation of a distinct Administrative Department, with uniform laws and regulations for the whole country.

CROYDON SEWAGE AND THE TOWN WELL.

Our readers will perhaps remember that in an article, No. VII, on "The Croydon Sewage Farms," we said "that according to the analytical inquiries of Dr. Frankland, as stated by Dr. Carpenter, the chalk well in Croydon, from which the water-supply for the town is obtained, is charged to a large extent with nitrates and the other oxydised products of sewage." This statement appears to have given great offence to some of the good people of Croydon, for it has been the subject of angry comment and correspondence in a local newspaper, *The Croydon Chronicle*. At first, our statement was described by the Editor as "a pure invention," for he said he was quite sure

that Dr. Carpenter never said anything of the kind. In proof of our veracity we gave, in our issue of the 12th inst., reference to the published writings of Dr. Carpenter, wherein he states that he and Dr. Frankland had publicly discussed the question. In reply to this we are now met by a wrathful declaration from Dr. Carpenter that we were not justified in associating his name with the subject, although it is difficult to understand how we could have done otherwise, seeing that he and he alone is the author of the statement alluded to, and that we should have known nothing about it if he had not raised the question, and put it into print. His letter, in fact, of Saturday last, to the Editor of *The Croydon Chronicle*, affords ample proof of this, notwithstanding that it also exhibits a most anxious desire, on the part of Dr. Carpenter, to repudiate the connection of his name with Dr. Frankland's, and to deny the facts in question, for he says—

> If you will allow me, I will explain how this idea of Dr. Frankland's arose, and how I became interested in it. Dr. Frankland had stated that the appearance of nitrates and nitrites in potable water was an evidence of previous sewage contamination, and that such water ought not to be used for dietetic purposes. I demurred to this dictum at the meeting of medical officers of health at which the statement was made, and asked Dr. Frankland to explain, upon his theory, why, according to his own analysis, the quantity of nitrates and nitrites in the Croydon well water should be greater when supplied to the inhabitants as potable water, than after it had been contaminated with sewage and had passed over the Beddington fields. (It should be mentioned that this is a peculiarity common to most waters obtained from deep chalk springs.)
>
> Dr. Frankland assumed that it must have been caused by percolation from the sewage farm.
>
> I at once objected to this as an impossibility, and stated that the objections against it were the following facts:—
>
> 1—That the surface of the water in the well was higher than the surface of the fields irrigated at Beddington.
>
> 2—That allowance being made for evaporation, as much water ran off the fields as ran on to them.
>
> 3—That the River Wandle ran from the neighbourhood of the well towards the fields, and would be more likely to supply the well.
>
> 4 and lastly—That the analysis of the water from the well, made by Professor Way, twenty years ago, corresponded very nearly with that made by Dr. Frankland, and that that analysis was made years before irrigation had been practised in Croydon.

It is not our purpose to discuss, at the present time, these several questions, but merely to show that we had good authority for saying that, according to the analytical inquiries of Dr. Frankland, as stated by Dr. Carpenter, the Croydon well water is contaminated with the oxydised products of sewage from the irrigated fields at Beddington; and in saying this, we do not, as Dr. Carpenter supposes, produce his name as a witness *in favour* of the statement, but merely as the authority of the statement itself, whether he is in favour of it or not.

We had hoped, as we said in our last communication on this subject, that if the discussion were continued some information would be given of the exact condition of the scheme for forming a company to rent and manage the sewage farms at Croydon; and how many of the towns people who have heard, and perhaps seen, so much of the valuable results of sewage farming, have taken shares in the project; for, after all, the most practical and reliable test of the value of sewage is the money confidence reposed in it by those who have really had experience of its profitable results, and have seen the magnificent crops obtainable from it in all seasons. On this head, however, the learned Doctor is silent, although it would undoubtedly have greatly enhanced the interest of the discussion if he had in some sort alluded to the subject, as by saying, for example, that he himself had largely embarked in the undertaking; but, perhaps this is too much to expect of him, for, to speak metaphorically, whoever heard of a doctor taking his own physic?

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The proceedings at the last meeting of the Council of this College were as satisfactory as they were important. Sir William Fergusson, with that straightforward and manly determination to do what is best for his profession, which we always admire in him, adhered to his determination to resign his examinership. Mr. Curling also, with his high sense of honour, maintained the position he has taken as a genuine reformer by declining to become a candidate at the ensuing election, on account of the active part he took in securing the separation of the anatomical and surgical examinerships. By this action he practically carries out the reform he has done so much to bring about. Of course, this is "without prejudice," as the lawyers say, to his position, in case he should at a future time come forward as an examiner in surgery. Indeed, we should say it ought to secure him the next surgical vacancy. No one is more capable—no one more respected, and we hope, therefore, to see him occupy a post for which he is eminently qualified, and which his present abnegation should certainly secure him.

The 21st section of the Charter of 1843 has hitherto been a dead letter. Now, at last, the College is fairly in the right way. We have actually a President and Vice-President who are not on the Board of Examiners. The names of Fergusson and Curling will be long quoted as those of men who gave a final blow to the obstructive policy that has done so much to injure the College. After this may we not look to them as leaders? There are several other points of importance that must come forward. The *Members*, as well as the *Fellows*, desire to have some privileges in their College, and to feel some tie to the great institution to which they are affiliated.

May we hope that the names of Fergusson and Curling may yet appear at the head of the long list of those who wish right to be done?

MORTALITY AND REGISTRATION IN DUBLIN.

The Registrar-General's Report for the quarter ending October 1 has just appeared, and as it affords some considerations of interest, we append an abstract:—

Births.—In the Dublin Registration District the number of births registered amounted to 2,034, being equal to an annual ratio of 1 in 39, or 26 in every 1,000 of the population. The number of births registered north of the river Liffey was 1 in 32, and on the south side of the river only 1 in 43 of the population. In Rathmines, Donnybrook, Blackrock, and Kingstown, the number was only 1 in 46 of the population. There were registered in London during the same period 26,953 births, being equal to an annual ratio of 1 in 30, or 34 in every 1,000; in Glasgow 1 in 25, or 40 per 1,000; and in Edinburgh 1 in 27, or 37 in every 1,000.

Deaths.—The number of deaths registered in the Dublin District affords an annual ratio of 1 in 48, or 21 in every 1,000.

Diseases.—The deaths from diarrhœa registered during the quarter amounted to 168, showing an increase of 50 as compared with last year; of the total deaths registered, 1 in every 9·8 resulted from diarrhœa. 92 deaths were caused by scarlet fever, or 1 in every 18 of all the deaths. 13 deaths were referred to measles against last year's 80 deaths. 77 deaths were caused by fever—viz., 24 by typhus, 28 by typhoid or enteric, and 25 by simple continued fever. The assigned caused of death in 138 instances was convulsions. 23 deaths were ascribed to croup, 26 to whooping-cough, and 3 to diphtheria. Bronchitis was the cause of 109 deaths; and pneumonia, or inflammation of the lungs, of 18. 82 deaths resulted from heart disease; 5 from aneurism; and 2 from pericarditis, or inflammation of the heart's covering. Disease of the liver, unspecified, was the cause of 28 deaths; hepatitis, or inflammation of the liver, of 3; and jaundice of 1. Kidney disease, unspecified, caused 8 deaths; nephria, or Bright's disease, 6; and inflammation of the kidneys 2. 205, or 1 in every 8 of the total deaths, resulted from phthisis, or pulmonary consumption. Mesenteric disease contributed 49 deaths; hydrocephalus, or water on the brain, 38, and scrofula 11. Cancer proved fatal in 35 instances. The proportion north of the Liffey was 1 in 42; and the number south of the river 1 in 48. In Rathmines, Donnybrook, Blackrock, and Kingstown the number of deaths registered was 1 in 62. The ratio of deaths registered in London was 1 in 43, or 23 in every 1,000; in Glasgow 1 in 39, or 26 in every 1,000; and in Edinburo' 1 in 44, or 23 in every 1,000.

The most obvious inference from these figures is that the system of registration is evidently quite inefficient, and the returns accordingly untrustworthy, except as an approximation to the truth. The statistics tell us that the births in Dublin were only 1 to every 39 persons, while we know that in London they were 1 in 30, in Glasgow 1 in 25, and in Edinburgh 1 in 27. In any case, so serious a discrepancy as this, especially as representing the proverbial fertility of Irish parents, would entirely discredit the accuracy of the returns, and that conclusion is irresistibly confirmed by the observation of the figures for each side of the Liffey in the same city. We are informed that residents to the north of the Liffey have children at the rate of 1 in 32, while those on the south side are prolific only to the extent of 1 in 43, and those in the suburbs in the proportion of 1 in 46. Making allowance for the supposed greater fructification of Irish mothers than their English sisters, we should calculate that the ratio of 1 birth to 27 persons in English and Scotch cities ought to lead us to expect a proportion of at least 1 in 23 in Dublin, and thus we are bound to conclude that nearly one-half of all the births in the south side of Dublin are never registered at all.

This conclusion is greatly to be regretted by us, inasmuch as it will afford occasion for comment as to the inefficiency of medical men as registrars in comparison to the police, to whom it was proposed to entrust the duty of collecting these records. We are not altogether certain that such a conclusion would be a just one, believing that unnecessary difficulties are interposed by the Act in the way of parents desiring to register their children's births. No person who has not been actually present at the birth can give the information, and that person has to go a distance on a given day, and perhaps lose much time in doing so.

Amongst the poorest classes there is often neither doctor or nurse present at the birth, and the duty of registration is thus confined to the mother or the old woman who lent a helping hand, one or both of whom may be engaged or sick, and neither of whom is likely to give themselves much trouble about registration. The fee is not sufficient to make it worth the doctor's while to go to the mother, and the mother may not be able to go to the doctor, and so the case is left unnoticed.

Notes on Current Topics.

About the War and Wounded

Our readers will remember that Deputy-Inspector Gordon and Surgeon-Major Wyatt were sent by the Army Department to report on the French hospitals, &c. They are now shut up in Paris and have taken their part in doing what they can in that position. We hear through a private letter, per balloon-post, that our esteemed *confrère* and contributor, Dr. Gordon was, on some days, very fully occupied in attending to the wounded brought in after the late sorties. We look forward with interest to the reports that will be made.

***

Whatever may be thought of the utility of subsidising the belligerent Governments by giving them money for the wounded, there can be no such scruple about the fund for distressed peasantry of the North-east of France inaugurated by the *Daily News* and to which we have previously alluded.

Mr. W. H. Bullock, the upaid agent of the Fund, describes the whole country round about Sedan as having been desolated by the war. The condition of the population of one village—which he speaks of as the type of hundreds—is thus described :—"There reigns at this moment sad want and distress everywhere—not yet absolute dearth, but plain unmistakeable famine is advancing with fearfully rapid strides, with pestilence in its wake. The famine may be stayed by help from without, and, if we can stay the famine, the pestilence, it may be hoped, may be stayed too. In some villages," he goes on to say, "an almost clean sweep has been made of every conceivable article of food, clothing, or furniture; the savings-banks have, of course, stopped payment in Sedan, where those of the peasants who made any provision for the future had deposits. The cattle-plague is carrying off those of their cattle not carried off by the Prussians. Their pigs and poultry have vanished; typhus and small-pox are ravaging the wasted villages; the cloth-weaving, which is combined with agriculture in the villages about Sedan, is at a standstill; there is no seed to sow; their unthreshed corn was either consumed by the German cavalry, or wantonly strewn about the fields for the bivouacs." The reader may easily fill in this fearful outline. Mr. Bullock has found, in the course of his inquiries, that in all this district not merely the comforts but the necessaries of life are wanting. With the means at his command he cannot afford to supply the sufferers with such essentials as mattresses, coffee, and sugar, but he is obliged to confine the expenditure of the fund placed at his command to the purchase solely of bread, lard for cooking the potatoes which yet remain, blankets, and warm flannel clothing for women and children, especially for the little children, who are perishing

for want of it. "A month hence," says Mr. Bullock, "it may be too late."

***

The large sums that have been raised by the charity of Englishmen have, no doubt, been difficult to apply, and we are not surprised at the complaints that have been made as to its administration. We have commented from week to week on the matter, and even predicted such complaints. It was next to impossible that it should be otherwise. We would maks all allowance for mistake and hurry. English people have a knack of being ready when the war is half over. We feel, however, the gravest doubts as to the propriety of handing over the two sums of £20,000 are equal sums to each belligerent. Such a donation, although expressly stipulated to be used only for the wounded—is a subsidy for each—for it only sets free a similar amount for warlike purposes. We doubt if many of the contributors to the fund would have subscribed had they known that the money would be applied in this way. We have no wish to find fault, but we feel strongly on the point, and we fear this is not the only weak point in the National Society. So many complaints have been made that we do not like to repeat them, but this one involves a great principle. As to the statements of partiality that have been made in some quarters, we hope better things and assure our contemporaries that no one sees partiality so soon as your thorough-going partisan. It is the strongest partisans of France who have cried out on this score.

***

One more special complaint has been made—started by the Society itself—it is said the Committee is so small that they are all overworked. We cannot but think there are many gentlemen who would give their aid freely enough. Work may be, in some cases, more useful than money, and is often given at a greater sacrifice, though just as readily. We know one or two who have been ready thus to help on the good work, and there must be others. The Committee is no doubt much too small, and now the Fund has become so large, a better organisation should be established.

***

Little is really known of the condition of Metz. Correspondents give most contradictory accounts in the assertion of deserters and prisoners. The following is a hopeful statement from the *Telegraph* :—

"The prisoners taken in the affair at Peltre, of which I wrote in my last letter, were sent out of Metz yesterday (Oct. 1), to be exchanged. They describe their treatment as of the best. They were served twice a day with excellent soup made from horseflesh, and also a sufficiency of bread. The only thing that seemed to be wanting was salt, which they say is now served out only to the officers. They describe the French troops as being in excellent spirits, and say that the soldiers talked, laughed, and joked with them in the most friendly way. They were not subjected to any examination respecting the disposition of troops, or anything at all connected with the arrangements of the German army ; nor were they ever visited by any General officer ; but quarters were immediately assigned to them in the suburb of Le Sablon, where they were exceedingly well treated, and eventually sent with a flag of truce to the nearest Prussian outpost. Their report only tends to confirm the opinion I have already expressed in your columns, that Metz la Pucelle will not be taken before winter shall have tried the resources and constitutions of the German army."

***

Other accounts repeat the distressing statements we have previously published. If we turn our attention to the besiegers, we have only confirmatory evidence of the extent of disease on which we have already commented. To the epidemics is now added the dreaded epizootic. The *Daily News* correspondent with the German army before Metz, gives the following sad account :—

"I am sorry to have to inform you of the increased and fearful prevalence of the cattle plague among the vast herds of cattle which have been accumulated in our rear for the supply of the Prussian troops. The plains between Remilly and Bazancourt, and around the latter village, are strewn with the dead. Whole herds have perished. Isolation is impracticable, nor is it possible to keep fresh arrivals off the ground infected by their predecessors. The orders are imperative that the animals which have died of this mysterious pestilence shall be buried as soon as possible, just as they have fallen. From personal observation, however, I can state that this order is not always complied with, and its enforcement must be almost impossible where the herds cover so large an area of ground, and the supervision must necessarily be perfunctory. Many a hide is taken off these dead bullocks before they are buried, and I have reason to believe find their way into the bottoms of the waggons belonging to the hordes of carriers, market-tenders, and what not, that come over the frontier towards Saarlouis, Triers, and Luxembourg. If the people, therefore, knowingly admit the unclean thing within their borders, their blood be on their own heads. Probably the hides are smuggled into the tanneries without the cognisance of the authorities. But the question is one of deep interest for Britain. No doubt the regulations for the import of live cattle from the Continent are framed so as to be effectual against the admission of disease. But Leadenhall and Bermondsey need be told that consignments of 'wet hides' occasionally come over from Continental ports, and it is no impossible thing that some of the surreptitious windfalls from Bazancourt and Remilly may find their ways into these parcels."

Leave of Absence of Medical Men from India.

A REVISED compilation of General Orders has been issued by the Commander-in-Chief, in supersession of the compilation promulgated in 1868. It provides, as regards medical officers, that the application for leave of absence for a medical officer can be proper only when, the regiment being healthy, the attendance of one of the medical officers can for a time be dispensed with, or that the indulgence of leave of absence to any particular medical officer is an object of most material importance to his private concerns or to the state of his health. Deputy-Inspectors-General of Hospitals, previous to availing themselves of privilege leave, must obtain the sanction of the Commander-in-Chief through divisional commanders and the inspector-general. Leave to medical officers on private affairs is restricted to one year.

The Fever Epidemic in Liverpool.

THE Union authorities of Liverpool are exercising a praiseworthy, if tardy, energy in the repression of the fever epidemic, and the disinfection of the districts in which it is most rife.

It appears from the proceedings of the staff sub-committee that they have resolved to authorise the medical officer of health to provide such a number of carts, and engage such men as might be necessary for efficiently carrying out the work of disinfection in houses where fever occurred. The clerk of the Toxteth Guardians had written to the sub-committee to the effect that the guardians were prepared to incur the responsibility of destroying worthless beds used by poor persons suffering from fever, if the committee would undertake the removal of the beds.

The guardians also thought that the disinfection of the clothing was likewise of great importance, and they therefore proposed providing clothing for those who had not a change, to allow of disinfection.

Alas! why is it that all the ardour of the sanitary authorities should be reserved until the enemy is at the gates, and the defence too late. Liverpool is exceptionally well provided for in sanitary matters. It is liberal enough to pay a salary worth the acceptance of a thoroughly good sanitary officer, and its sanitation is accordingly ten times better cared for than that of other cities. And yet how short a way it approaches to perfection.

Hear! Hear!

We read in the *British Medical Journal*:—

"The British Medical Association never appears to greater advantage than when occupying itself with questions of public medicine, it addresses its energies to the solution of problems of sanitary organisation."

Such a declaration should be written in letters of gold as a mediæval decoration of the Council chamber, and then perhaps the administration of the Association could spare something more than a thousandeth of its income for those purposes which, we are told, are the brightest jewels in its crown.

The New Session.

The number of entries is eighteen more than last year. The total number of students now pursuing their careers in the eleven London Schools reaches the figure of 1,298. Guy's heads the list again, having 102 new entries. Charing Cross Hospital is at the bottom with 9 new entries. The remainder are distributed amongst the several schools. The freshmen altogether in London are 433.

Pharmacy in Medical Schools.

The University of Durham College of Medicine at Newcastle has arranged a curriculum for Pharmaceutists, which seems to promise well; and those actually engaged in pharmacy, who enter during the next twelve months, may have a perpetual ticket for the whole for £6 6s. We advise all who can to profit by it. It includes botany, materia medica, chemistry, and pharmacy. Now, the three first are taught in every school of medicine, and the last should be also. We are inclined to think, at any rate, that the instruction in pharmacy might be advantageously placed under the superintendence of professors of materia medica, whenever they felt able and were willing to take it.

The writer has seen in many ways the immense value of a knowledge of pharmacy, and has observed numerous instances in which such knowledge would have benefited his brethren. He can trace a certain degree of success to an intimate and practical acquaintance with pharmacy. Although he would willingly see the two callings as far as possible separated, he thinks every medical man should understand pharmacy. He thinks no one can be said to be up in his materia medica who is ignorant of pharmacy, and he considers that every physician and surgeon should be able to dispense his own prescription. Unfortunately, there are too many familiar instances that such is not the case.

The London Hospital.

Our readers know that at this large hospital, the assistant officers are after seven years' service promoted to full rank, even although they may not have any change of duties. Under this regulation, Dr. Hughlings Jackson, F.R.C.P., has lately become full physician to the hospital.

At the London too, the assistant-physicians and assistant-surgeons, enjoy some other privileges, and in many other respects there is great liberality at this hospital. There have been some recent improvements, to which we propose shortly to direct more particular attention.

Yellow Fever.

We learn that an outbreak of this disease has given some trouble at New York. The Board of Health after investigation, has pronounced that such is the nature of the disease, and quarantine hospitals have been called into use. It is supposed to have been brought in the first instance to Brooklyn Docks, by vessels from infected ports, arriving as early as last August, and to have been smoulder ing ever since. It is believed that deaths among the troops on Governor's Island, returned as due to remittent, have usually been caused by yellow fever, and now that it is decided to be amongst the citizens, very active measures have been taken.

Unattached Students.

At Oxford the Vice-Chancellor, the Rev. the Principal of St. Mary Hall, the Rev. C. L. Wingfield, M.A., Fellow of All Souls, the Rev. G. W. Kitchin, M.A., Christ Church, and the Rev. G. S. Ward, M.A., Magdalen Hall (censors). have just issued their report on the working of the new system, under which students can enter the University of Oxford without being attached to the College or Hall. The report says:—"During the year ending with the Trinity Term, 1870, the delegates in charge of students not attached to any College or Hall have entered forty-seven students on their books. Of these, thirty-four matriculated as *scholares non ascripti*, the remaining thirteen were members of the University who migrated to the Delegacy. In the course of the year twenty-eight names have been removed; one by death, three by withdrawal from the University, and twenty-four by migration to College or Hall; and of these, one as a scholar, five as exhibitioners, and eighteen as commoners. Of the eighteen, six were originally members of College or Halls who have returned again to collegiate life. The total number of entries from the beginning of the system in the Michaelmas Term, 1868, to the present time is 106, of whom seventy-two are still on the books. The system has not yet been long enough in operation to allow the students to appear in the class lists. A voluntary return made by twenty students enables the delegates to answer, with some confidence, the question so often asked, namely, what is the yearly cost of the system to a careful graduate? The average weekly cost of living—board, lodging, and extras—on the twenty returns, was 31s. But if the lowest ten be taken, the average falls to 26s. Taking this average as the sum per week for which a thrifty student can get respectable board and lodging in Oxford, we arrive at the following figures for a-year's expenses:—Board and lodging for three terms of eight weeks, at 26s., £31 4s.: University dues, £4 10s.: Examination fees (on the average), £1 1s.: Tuition expenses (about), £10 10s.: total £47 5s. It will of course be observed that these

figures do not include travelling, books, clothes, pocket-money, or cost of living in the vacations. Still, they prove conclusively that a careful student can get through his Oxford career for a sum not exceeding £50 a-year."

Cambridge University Electoral Roll.

The Vice-Chancellor has just promulgated the revised electoral roll of the University for the ensuing year. It contains 309 names, headed by those of the Duke of Devonshire, LL.D., Trinity, Chancellor, and the Earl of Powis, LL.D., John's, High Steward.

Registration of Diseases.—Deputation to Mr. Goschen, M.P.

On Monday afternoon a very large and important deputation waited upon Mr. Goschen, the President of the Poor-law Board, to urge upon his attention the desirability of making arrangements to establish a Registration of Diseases. The deputation was introduced by Mr. C. E. Cawley, M.P., and Dr. Lyon Playfair, M.P., and comprised Dr. Rumsey (Cheltenham), Dr. Morgan (Manchester), Dr. A. Ransome (Manchester), Dr. J. Harley, Dr. Gibson, and Dr. Farre, London, representing the British Medical Association; Dr. Day Goss, Dr. Ainslie, Mr. Ernest Hart, Dr. Carr, Dr. Fowler, Dr. Stewart, Dr. Ogle (Derby), Dr. Manley (West Bromwich), Dr. Aldis, Mr. Randolph Robinson, Dr. Rogers, &c., the Poor-law Medical Officers' Association being also represented. Dr. Lyon Playfair, M.P., having introduced the deputation, Dr. Rumsey said the object of the Association was to get the Government to adopt a plan of registration of disease in connection with the system of Poor-law medical relief and the relief afforded at public hospitals and dispensaries, and it was proposed to be done at the public cost. The registration of disease was regarded as necessary for the proper administration of general medical relief. It was also essential before any sanitary legislation could take place, and it would be beneficial to science. The proper organisation of medical relief would involve the adoption of the dispensary system, such as exists in Ireland, and a revision of many of our charitable hospitals and dispensaries. The cost was proposed to be left to any department the Government might think best. The President said he thought the arguments in favour of the value of registration of diseases were so clear and strong that nearly everyone would accept them; and the chief point for consideration was by what machinery it could be carried out, with what rapidity, and at what cost. The question of cost would not be for his department, but would be determined by Parliament in the estimates; but if the scheme could be carried out effectually, and at a reasonable cost, he should like to know what was the estimated expense of getting the returns and codifiying them for use. Would the medical officers co-operate in the matter? Dr. Morgan (Manchester), replied that in Manchester the medical officers had co-operated, and he believed they would require only a small remuneration of something like £3 3s. a-year. The President said in conclusion that the Royal Commission's report would determine to a great extent many of the questions under discussion, and as regards the registration of diseases, it would not be desirable to take any steps to carry it out till that report had been issued, which he hoped might be before the end of the year.

The Red Cross.

The old feud between the combatant and non-combatant branches of the military service, has extended to the Red Cross Knights attending the sick and wounded in France. Many of our professional brethren have returned disgusted by the treatment received at the hands of the German officers, who look upon them with undisguised aversion and suspicion.

They are quite willing to accept money and material, but prefer to dispense with the personal assistance of the officials of the National Society for Aid to the Sick and Wounded.

We understand that Col. Loyd Lindsay, who has just returned from Paris, having been permitted by the Prussians to pass into the city, complains bitterly of the difficulties thrown in the way of the representatives of the society.

The Germans on their part, assert that the Red Cross is often assumed as a disguise by spies and others.

The After-taste of Quinine.

In practice there is often experienced a great difficulty in getting patients to take quinine, because of its after taste, which to some is simply unbearable, and when antipathy thus exists, combined with a difficulty in swallowing pills, the therapeutic value of an important drug is lost. We find, and the fact may not be generally known, that the mastication of some acid fruit, as an apple or a pear, will permanently remove the disagreeable after-taste of quinine. The first mouthful of fruit should be well masticated and rolled through the mouth, so as to cleanse the teeth, &c., and then ejected. The second morsel may be swallowed, when it will be discovered all taste of the quinine will be removed.

The Sick Lion System.

Once and for all we beg to express our disgust at the common practice of our contemporaries who, taking advantage of the indisposition of a statesman, or noted member of Parliament, or an aristocrat with a handle to his name, ferret out in a most unbecoming manner, to a most discourteous and unprofessional extent, the exact state and condition of tongue and skin, and what cannot be dissected out, call to acquisition their imaginary faculties in order that a neat little sensational paragraph may be made for purposes of quoting by other journals. It is most unjust to the ailing patient, and to his relations. The first tidings are generally alarming; the consequence is, friends become frightened and loose confidence in those who are in professional attendance, since they have good grounds for supposing and believing that the truth is not spoken, and that the impending dangerous nature of the case is veiled from them when they come to read tidings of alarming danger republished in the morning papers, and quoted in authority from a medical journal. It is injurious to all until the Second Edition throws oil on the troubled waters. We have no desire to make personal remarks expressive of our dissatisfaction in the *Sick Lion* system, or reproduce here the expressions of disgust which have reached us, emanating from the relations of sick persons who have been unfairly dealt by, and from members of our profession, who, to speak the truth, have been temporarily injured, for although not directly superseded, others unnecessarily are called in who share—have unduly conferred on them—the credit of

the case. We are told that it is done for an object—either to injure some medical man, or to push on others. This on behalf of our fellow journalists we repudiate ; but we agree with a clever corrrespondent—a member of the English aristocracy—in his observation that a sick man's case during the progress of the disease, should be no more commented on in a public journal than a trial before the jury have returned their verdict. This, we trust, is the death bell toll to the vulgar unprofessional "Sick Lioning" system.

Post-office Grievances.

The Post-office we are told has not been so successful in its business as formerly. There has been an evident falling off in profit. The new telegraphic department has also not paid so well as was expected. Will the new halfpenny postage remedy this? We expect not, but still would be satisfied, if it were managed as well as it should be. It is not the first purpose of the department to make a profit. What is most of all demanded is public utility. Some of the grievances complained of are small enough, others are of vital importance. All our subscribers have for more than thirty years received their journal stitched, but under the new regulations we are forbidden to give them this convenience, and many naturally complain that the leaves are apt to fall out. When the matter was under discussion we did all we could to obtain the removal of this restriction, but without effect, and now our subscribers would do well to address their remonstrances to the General Post-office. This uncalled for regulation applies to all journals, and hundreds of respectable young girls are thrown out of employment by it.

Again, we cannot but think that better regulations might be made for obliterating the stamps or covers, and thereby avoiding a certain delay that is now taking place. Why cannot journalists be allowed to prepay *en masse* and affix no stamps at all? Or, if these precious stamps are to be insisted on, why could not the last office instead of the first obliterate them?

As to the new cards they are very useful for short messages, and the few complaints made will, we hope, soon disappear.

The Office would, perhaps, confer a further favour by selling stamped envelopes at one penny each, and thereby induce many to use them who for convenience will use the cards. Good quality envelopes supplied for the penny would be better for the office than a general halfpenny postage to which we seem rapidly tending.

No Dose! No Pay!

A Homœopathic paper has amused its readers at the expense of our profession by the publication in detail of the medical bill, alleged to have been delivered to the executors of a lady for fourteen months' doctoring. The total amount of the bill was £113 odd, and it included 870 bottles of medicine and 131 boxes of bills—about three prescriptions for every day of the fourteen months.

Whether our infinitesimal contemporary be only "poking fun" or not, we have a text for our condemnation of the system of doctor-drugging which the *Lancet* is so anxious should flourish. It is ridiculous to expect that the overdrenching system which has driven many victims into homœopathy shall cease, as long as the major part of the practitioner's income is made up of drugs, and the smaller of medical skill. If a general practitioner does a sovereign's worth of work, and is forbidden to ask for more than half-a-crown for his attendance and skill, he necessarily administers seventeen and sixpence worth of medicine and the result is 500 bottles a-year. The motto of the present system is, "No dose, no pay," and we cannot be annoyed or surprised if we make ourselves ridiculous by our efforts to comply with the principle.

A Combination of Leech Sellers.

The competition amongst tradespeople, and the great increase in their numbers, have made impossible in our times the combination between the dealers in any one article to create and keep up excessive prices of which we heard so much twenty years ago, but it seems that the system of "rigging the market" is not yet forgotten by traders whenever the smallness of their numbers or any peculiar circumstances have enabled them to overcharge for their goods. The *Chemist and Druggist* has exhumed a conspiracy of this sort amongst the London dealers in leeches, which it thus describes:—

"Certain leech importers in London, not making their fortunes fast enough, have come to the conclusion that this state of thing might be much improved, for them at least, by simply choking competition. Secret negotiations were carried on, and most, if not all, of those engaged in the business in London were communicated with, and much unanimity was expressed. A strong hope was entertained that all the members of the craft would eventually join this precious fraternity, and a most solemn league and covenant was decided upon whereby it would be agreed to fix a minimum price for leeches considerably higher than the normal quotations. The Franco-Prussian war is the immediate disturbing influence, but the opportunity (which an old proverb tells us, is often responsible for a deterioration of integrity) was by this means created, of which our keen commercial friends saw advantage might be taken. On Tuesday last a meeting of these leech gentlemen was held to consider the matter, with what result, we are not in a position to inform our readers."

We have no fear that any such organization of pharmaceutical "bulls" will succeed in inconveniencing the public or the Profession. There will always be a sufficient number of dealers urged by money interest, if not by honesty, to stand aloof from such combinations, and take advantage of the rise in price to get the trade into their own hands ; and we imagine these traders will soon discover that their conspiracy is no more sensible or practical than it is honest.

Yellow-fever prevails at New York.

There will be accommodation for about 550 patients at the Highgate Infirmary. The nurses will be of Nightingale training. Was it sensible to have such a large hospital, after all the late Sir J. Y. Simpson has written?

Scarlet-fever, according to Dr. G. Johnson, is sometimes propagated by means of linen sent to laundresses to wash. It is, therefore, safer to wash our clothes at home. But, then, must we not get scarlatina at some period of our lives? Why not when we are young, and can be more easily spared if we die?

The Anatomy Act gives hospital authorities the power to make a *post-mortem* examination, provided no objection is offered by the relatives of the deceased.

Horseflesh is said to sell for ninepence to a shilling a pound in Paris just now. After all, why is it that our poor people, who so seldom get meat, do not occasionally get a little of what seems to be a palatable and wholesome kind of food. But, then, poor cats would complain as they consume boiled horses to a great extent.

A meeting of the Fellows of the Royal College of Surgeons in Ireland will be held on Thursday, the 3rd November, at one o'clock, pursuant to the provisions of the Supplemental Charter, to elect a Member of Council in room of Dr. Barker, resigned. The ballot will close at Three o'clock, when the scrutiny will immediately take place. Fellows who may desire to have their names printed on the lists of Candidates for the office are requested to signify their wish, by letter, to the Registrar of the College, on or before Saturday, 29th October.

In the Manchester Medical Society on October 5th, Dr. Bradley mentioned a case of rupture of the gall bladder. Death occurred in six hours, and pus and bile were found in the peritoneal cavity. Dr. Simpson related a case of tubercles in the cerebellum, in a lad aged fourteen. There was palsy of the internal rectus of left eye. He had want of co-ordinating power in walking. At the *post-mortem* examination a little lymph was found about the optic commissure, the whole brain substance softened, particularly at the base. Both cerebellar lobes contained numerous yellow masses of tubercle from a pea to a marble in size. No tubercle was found in any other part of brain or other organ. Dr. Simpson also gave the case of a girl, aged nine, with hydatid tumour of the liver. The tumour was the size of the fist; and a small quantity of fluid was withdrawn by a subcutaneous syringe. A slight peritonitis followed, but the cyst disappeared. Would it not have done as well if the cyst had burst of its own accord into the peritoneum?

SCOTLAND.

University of Edinburgh.—Lady Amberley having offered a scholarship of the yearly value of £50, tenable for three years, to the lady who should pass most successfully the medical preliminary examinations in arts held last week, the examiners have declared Miss Emily Bovill to be the successful competitor. Four other ladies presented themselves, and passed the board.

Royal College of Surgeons.—Dr. Andrew Wood has been re-elected representative of the College in the General Medical Council.

We are glad to learn that an effort is being made to complete the memorial in the University of Edinburgh, begun some years ago, to the late distinguished Professor Goodsir, and which is to take the form of a scholarship in anatomy. £600 have already been subscribed, and a further sum is still required. This amount it is confidently expected will speedily be realised, and we trust intending subscribers will remember the adage, *bis dat qui cito dat.*

Correspondence.

THE PROFESSION AND OURSELVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,— Whilst the Bill lately introduced by Government occupied the attention of legislators and others enthusiastic on the subject of Medical Reform, I dared not presume to express an opinion on a question of such vital importance, and one whose solution seemed to puzzle the wisest legislative intelligence of the day. It has, for the present at all events, been laid aside, and Medical periodicals have ceased to be monopolized by correspondents whose theories regarding professional abuses, and their proposed remedies, were as numerous as they were dissimilar and impracticable. I therefore, albeit with some hesitation, crave a corner of your journal, at every juncture so ready to serve our profession, in order to call the attention of your readers to the fact that it is only within later years that the members of our profession saw that there was a necessity for parliamentary interference in order to preserve, or rather, in reality, to reform the pristine dignity of their art.

'Tis strange that advancing science has failed in itself to maintain the *status* of medicine, while, at the same time she has so steadily and rapidly added to the accomplishments of every branch of her extensive domain, and thereby increased her utility to mankind; there is no profession now whose scientific achievements adds an equal number of brilliant gems to the coronet of science as does ours; none which has sent forth a greater army of illustrious intellects to the battlefields of philosophical inquiry, and none whose labourers have alike reaped the golden harvest of retarding the temporal victories of death, and alleviating the earthly trials of suffering humanity. Notwithstanding, Sir, we cannot shut our eyes to the fact that nevertheless the members of our body have in a manner deteriorated in social regard; whilst the Bar, Church, Army, and Engineers still points to the colours under which they respectively serve as pathognomonic insignia of "the gentleman;" the time has, I fear, gone by when the "professional stamp" of medicine or surgery was sufficient of itself "to mark the man." We now see the dire necessity of obtaining authoritative means to retrieve what we ourselves should have year by year maintained—the prestige of "the Profession and Ourselves."

To whom is this deterioration due? To the Licensing Corporations who are the educational representatives of the Profession, or to ourselves? Can the blame be laid solely at the doors of the former? Can the fault be alone ascribed to their monetary covetousness, to the apathy of examiners, to imperfect curriculums, or to the facile obtaining of their licenses? No, Sir! Had medical gentlemen (as they ought *facile princeps* ever to have been) maintained collectively that they were *per homines honestissimos* medical reform should never have been required; had they upheld their dignity before the world at large, not by paltry, though perhaps loud, declamations regarding "professional etiquette" and "professional status," but by endeavouring to follow more accurately the example which the great Physician Himself left us in the very dawning of modern physic, we should have preserved a prestige in Society as untarnished, as our scientific reputation is unsurpassed. I should be far from being understood to say that the arduous and self-sacrificing duties which ever and anon devolve upon the medical practitioner have not been nobly undertaken and as nobly accomplished; I should be far from speaking disrespectfully of the very large majority of our body who are ornaments to any society they may move in; gentlemen, in the true sense of the word, submissive and inobstrusive, without being servile to those superior to them in learning or position, affable to their equals, kind and forbearing to their inferiors, and courteous to all; gentle to those in suffering—unmindful whether they be poor and rich; peaceable and forgiving towards each other and the public; always making allowance for an erring or less fortunate brother; unostentatious, ready ever to throw lustre on the Profession by endeavouring to raise that brother, even if a rival, in public estimation, rather than add the slightest iota to his degradation by word or deed; and besides, scholars, not only in the theory and practice of physic and surgery, but accomplished forsooth in the more general branches of science and erudition which assist professional study and refine the mind. What I

mean to convey, Sir, is this, that the exceptions to the rule are getting by far too numerous. The profession should show its distaste for anything ungentlemanlike or unkind, its abhorrence of professional squabbles, which tend most materially to prostitute its fair fame and its love of the refined; we should show the public that ignorance we would not tolerate in any member of our ranks, but that we required a high standard of proficiency in both general and special education, and that we not only scouted "shady diplomas," but any members of our body who aided in their being granted. Till we act with more unity, it will fail us to keep our profession as it ought, "διχθαδίας Κηρας φερέμεν θανάτοιο τέλοσδε" till then the uneducated and unstrung will be found gaining access to our ranks; then, and not till then, will the "bone-setter," and the "cancer-curer" be exterminated; then, and not until the injunctions of "Medical Ethics" and professional unity are more strictly observed, shall we succeed in *reforming* "the Profession and Ourselves."

Please accept my individual thanks for the services rendered the profession by your widely circulated organ, and the scientific assistance it records to those who, though qualified, are "Students still."

I am Sir,

Your obedient servant,

FRANCIS E. CLARKE, M.B.

Oughterard, Galway, October 19th, 1870.

CONTAGIOUS DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In this week's number of the MEDICAL PRESS, there is a report of the Chief Commissioner of the Police to the Board of Admiralty, on the operation of the Contagious Diseases' Acts in Plymouth and Devonport districts.

If the numbers are correct, and I suppose they are so, as much as could be ascertained, there is an apparent improvement in that district, with the exception of Portsmouth, where the percentage of the soldiers treated for venereal diseases has not much altered, being in 1865, 19·83 per cent., in 1869, 19·81 per cent., showing at all events, that there the police system did not do much good, although we know that a new broom sweeps clean, so I think we must still wait before giving a decided opinion and accept the police system even in garrison towns.

The Report shows also that 49,389 women free from disease had wantonly been examined during these five years. Now, Sir, what excuse can be made for such a system, by what right were these 49,389 harmless women subjected to such a degrading ordeal, I am not astonished that 2,538 girls left the district, and where did they go? The Report says, it is believed that they have returned to their friends.

This is only, I am afraid, a *police illusion*, and very contrary to what we know of human nature and of the conduct of these unfortunate girls, who generally prefer every kind of privation and misery rather than go back to the locality where once they were innocent and blameless.

As for the clandestine prostitution having diminished, I rather suspect that it will be found by-and-by that it will be in that district, as in Vienna and Paris, and every town where this revolting police system is carried on, and where private prostitution is every year on the increase.

I think I read the greatest part of what has been written on the subject, and I am still of the opinion that nothing will tend so much to diminish prostitution as to put every *obstacle imaginable* in the way of the men who frequent these unfortunate women, such as medical inspections and the police regulations, which I mention in my former letters, they may be thought harsh and arbitrary, but they are not more so than those adopted against women, and we must consider that the men would become the objects of it of their own accord, and without being forced to it by any of the circumstances which influence these poor unfortunate women, such as seduction first, then desertion, misery, want of work, and starvation.

I have the honour, &c.,

E. L.

BABY-FARMING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I entirely agree with the spirit of Dr. Waring-Curran's remarks in your journal to day. The feeling of the public has been all wrong with reference to the crimes of seduction and infanticide, the seducer is regarded too leniently, and in some circles, with shame be it said, his profligacy is considered a feather in his cap! The poor victim bears all the blame, as well as all the sorrow and hardship of her fall, until driven to desperation she adds child-murder to the catalogue of her wrong doings, then Society feeling repentant at its harshness, begs the law to withold its hand; thus infanticide goes unpunished, so seduction and baby-farming and child-murder thrive.

The only way to stop all this, at least to check the evil in some measure, is to make seduction a crime. A society for the "protection of infant life" is talked of, it is to be hoped that no half-measures will be attempted; such a society may do much good if in earnest, it should hunt up and expose the "gentlemen-scoundrels," who are the pests of society, a few exposures of names would strike terror into their midst, for although they are well known in their own set, they manage to keep a fair side of their character to the public view, and to be "black-balled" by a conviction, which would ruin their social prospects. This is the most terrible deterrent that can be held out to them. The following paragraph is from the *Pall Mall Gazette*, and it is so much in accordance with my own views on this subject, that I will conclude my letter with the extract.

"The confession of the wretched woman Margaret Waters discloses a state of affairs sufficiently humiliating to our pride of civilization; but its disclosures, supposing the whole of them to have been made public, have not involved the aristocracy in that disgrace and scandal which the readers of the 'penny dreadfuls' were led fondly to expect. The stories of handkerchief marked with coronets and aristocratic female names having been found among Margaret Waters' effects have melted into thin air. There has been a notable absence of the wicked earl. The clientèle of Margaret Waters, so far as it has been at present investigated, appears to have paused at the level of the upper middle class. 'Among her clients,' we are informed, were a chancery barrister, a well-known gentleman in another profession, and a gentleman whose name was very much before the public in connection with another matter. The two latter gentlemen will, we imagine, have little difficulty in maintaining their incognito under this description."

I am, Sir, yours obediently,

October 19th. PRUDENTIA ET JUSTITIA.

AMMONIA IN HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have reason to think that ammonia will cure the affection or disease, called water-fear or hydrophobia. The poison appears to act chiefly upon the nervous system, upon which ammonia has a powerful effect. I would rub the throat and chest with a strong solution, and also throw it up the rectum, and if possible give it by the mouth. I think ammonia will be serviceable in "Tetanus, &c." I had a case of this latter at Maderia in 1831, from an accident. The officer, a middy of nineteen, was thrown from a pony and received several scratches, superficial tetanus succeeded, his brother was one of my assistants; I held a consultation, and opium was our dependence; I applied ammonia to the nose, and it appeared to relieve the spasms, but it did not appear to me then to have any particular influence; consideration and reflection has induced me to believe that ammonia will prove serviceable, at all events it is worth trying.

I throw out the suggestion, and hope and trust effectually,

Yours, &c.,

ALEXANDER LANE, M.D., R.N.

Clun Salop, October, 1870.

THE VICTIMS TO SEDUCTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Observing a letter in your last issue on the subject of "Punishing the Seducer," I wish to make some comment on it, which may startle a little those who, like many clergy, we hear occasionally denouncing "the monster" with all the earnestness of truth, indulge in the flowery rapsody of your correspondent, who has discovered "the unmarried well-looking squire ever on the *qui vive* to betray and to destroy?" If such an animal exists, and I conclude your fervid correspondent supposes that every village must possess a few, he certainly should be caged

and exposed; but though the theory may be very plausible, that "we all know the seducer—no town or country village," according to the writer, "is without him," and that "the root of the evil exists with the men," I do not by any means allow it; or, that though passion may, no doubt, warp and overpower man's better nature and feelings, can I agree with your correspondent that the maneater, in such a shape as he has depicted, lurks about our towns and villages. Nor can I at all admit, in this country at all events, the truth of the proposition, "that all this time Seducer, Esq., is at large, boasting, perhaps, over his exploits, and hailed by his admirers as a hero." No doubt, to a great extent, this is the popular view, this looks very like what might be the case; but unfortunately for the denouncers of "the squire who is ever on the *qui vive*," the theory is but a theory, and exists with but a few exceptions only in the excited imaginations of old ladies, good natured clergy, and some like your frothy correspondent, who hastily have recourse to anathematizing an imaginary monster. Let us view the subject calmly and practically. As I have been connected with an institution which admits many hundreds of these "victims" annually, I may claim some attention, and avert from our sex some of the execrations that have been invoked on the "hero," "who is fawned on by his friends, and enthusiastically received into society with open arms," so says your correspondent, conferring certainly not a very graceful compliment on his neighbours, or the country which supports him.

The practical fact is, that the chief seducers are women and dress — woman is still the Eve, even of her own sex, it may seem very hard to say so—and may seem very contrary to all her attributes of kindness and solicitude, but such is the fact, and such can be proved beyond question in very numerous instances.

The tale is often repeated, I might say in nine cases out of twelve, a girl living at home with her family, or earning her bread honestly, through perhaps hardly, meets with a female companion, perhaps by chance, perhaps in the course of her business or trade; this companion has herself fallen; directly she sets to undermine the happiness of her friend, *she* instils the poison, shows her that her trade or her business is too hard, that confinement is irksome, and that she may easily escape it. Incredible as it may appear, she often makes the preliminary arrangement for her destruction, and lures her hitherto virtuous companion to a place of preconcerted meeting, or to some concourse where she will be sure to fall; nay, more, she will share the spoil of her ruin.

This is the great cause of the fall of many young servants and work girls, specially where congregated together; one or two black sheep will do incalculable mischief, and each fresh victim who falls becomes in turn a seducer, and that of the most dangerous and insidious character. No doubt the man is the instrument, and those are easily to be found who are but too prone to indulge their licentious habits. While I join in reprobating, I must absolve him from the more detestable crime of silently and assiduously undermining the moral difficulties in the unhappy creatures who fall. "Evil communications corrupt good manners," and a young girl once fallen, *as she may long be undetected*, becomes one of the most subtle elements in the destruction of her sex.

Again, it is by no means very unusual, and admitted by many who have fallen, that they have left home and deliberately went on the town *proprio motu*, sometimes from the influence of recklessness; sometimes, and not unfrequently, from their homes being rendered unhappy by a stepmother, or from some domestic difference, they determine this course.

The love of dress is a most powerful influence—which the present fashion seems specially to favour, from its style, and from the opportunities afforded of showing off the natural endowments of hair, good figure, good feet, &c.; the facility for imitating and appearing "the lady," offers great and irresistible attractions.

In neither of these circumstances does the monster "Seducer, Esq.," or "the squire on the constant *qui vive*," play any conspicuous part.

Let us take another source of destruction, where woman is still the instrument—such cases as these actually have come within my knowledge during the last few months. A virtuous country girl living at home is induced by a neighbouring, and perhaps undetected, girl to rob her father of his savings of 10*l.* and 12*l.* to go to America. They proceed to Dublin; the inducer brings the innocent girl to a lodging of what turns out doubtful character; she takes care of the stolen sum; they go to bed—but by morning the inducer has disappeared, taking her victim's money and even her clothes; her fall is soon secured by the inmates, her own sex. She becomes a mother and is logged for life.

Another young girl of seventeen robs her father of 30*l.*; her inducer, a girl, accompanies her to Liverpool, takes the money to secure their passage and berths for America, tells the as yet innocent victim to wait for her in the street, where, of course, she is left, friendless, pennyless, and victimized. She cannot return home—and falls.

Here, the seducer, man, was not present to exercise his *qui vive*; woman sacrificed one of her own sex for her selfish purposes.

Let us take examples of another kind, where the greatest and most affectionate efforts have been made to prevent or reclaim this unhappy tendency.

A young girl of seventeen was taken back by her parents, well-to-do people, who found her on the town; fearing her again returning, till suitable arrangements were made they locked her in her bed room without any clothing but her chemise, nevertheless she escaped in this condition out of the window, and, with a few shillings she had secreted, got dress sufficient in a neighbouring dealers as enabled her to return to her associates.

Another girl, the daughter of respectable people, was induced to go home. She was allowed no money in the hope that she might remain; but she escaped, and sold her hair to a fashionable hairdresser for such a price as enabled her to refit and launch out again.

Here, there was no seducer, nor inducement held out to continue an evil course, but a home was tenderly afforded by parents in rather respectable ranks of life.

What is to be said about married women who leave their husbands or deceive them?

What about widows who not unfrequently fall? What about mother and daughter? Not long since a mother had three daughters at this institution; at present a mother and daughter are inmates. There was no "silken woven web here to entangle the victims." The question is not one to be disussed theoretically, nor by "blowing off" against the gentleman "well to do in the world—gifted in the art of pleasing, and blessed by nature with good personal appearance." This may be a very good stage property for a heartless deceiver, but the frequent existence of this monster is, I conceive, eminently theoretical, and unsubstantial; and "that such a man is fawned on by his friends," is simply, as my experience goes, preposterous, and certainly with us, I am happy to say, is untrue.

I do not for a moment suppose that there are not very bad and licentious men, and men who are, to a great extent, the slaves of their passions; but that these are the men that cause the fall of so many of the opposite sex I deny; the fact is there is a moral want. There is a *mal au fond* with some girls, often manifesting itself when they are very young, that we cannot well explain. How is it otherwise that there will be five daughters, one will go wrong and nothing will reclaim her, and the four could not be induced to err; or, a virtuous mother will have an only daughter, and yet she will fall and be irreclaimable. How is it that so few, indeed, I doubt if any, cases of real and heartfelt reformation occur, and that even after years of restraint they will again lapse and become more corrupt than ever. There is a moral defect which, much as it may be lamented, is very difficult to combat, and the same deficiency which led to their early fall still swerves them from virtue's path, when to all appearance some hope may have been awakened as to their security.

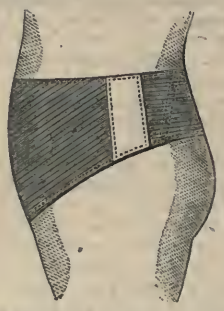
The great want is education—"Just as the twig is bent the tree's inclined." No doubt, "cæteris paribus," the better the education the greater is the security from falling into the ways of degradation, or giving way to the temptations of idleness—sloth and dress. Yet there is doubtless an inexplicable leaven which ferments with some to their destruction, while others are so guarded by the sanctity of modesty, that even your correspondent's incarnation of the Seducer Esq., "though graced with polished manners and fine parts," would find thoroughly and certainly impregnable.

Yours, &c.,
"VERITAS."

The Berlin Society for Help to the Wounded dispatched a few days ago an ambulance from the capital of Prussia to Pont-à-Mousson, under the direction of Professor Virchow. They carry warm clothing for the troops, medicines, and disnfecting agents.

MILLER'S IMPROVED ABDOMINAL BELT.

We have inspected a new belt for ladies, devised by Mr. Miller of Leicester square, of which the following engraving will convey an accurate idea :—



The principal advantage is, that the front elastic being woven diagonally, there is no necessity for extra lifts from below. The belt is, therefore, much lighter in weight and consequently cooler in wear, and we fancy that when once tried, it will be preferred by ladies to any other form.

Medical News.

The Midland Medical Society.—At the opening of the session in the Midland Institute, Birmingham, on Wednesday, the Council Report told unmistakably of increased usefulness and prosperity. Nineteen Fellows were added during the past session, and the resignations had never been so few. It was admitted on all hands that the retiring president, Mr. S. A. Bindley, had powerfully contributed to the satisfactory state of things. Dr. Keyworth has been elected his successor. Mr. J. St. S. Wilders, the senior secretary, has retired, after holding the office very ably for five years. Dr. Sawyer and Mr. Slingsby Mann are now the secretaries of the Society.

The Cholera in St. Petersburg.—The *Golos* states that, up to Sept. 11th, there were 107 cholera patients in the Civil Hospital. From Sept. 11th to the 18th, the number increased to 151 ; from the 18th to the 24th it rose to 185. Out of these patients, 52 recovered, 89 died, and 44 were improving.

Dr. Wm. Johnson Smith, of Weymouth, has been placed on the Commission of the Peace for the county of Dorset.

Royal College of Surgeons in Ireland.—A vacancy has been created in the Council of the Royal College of Surgeons in Ireland by the resignation of Dr. James Barker, whose health, we regret to learn, obliges him to withdraw from the collegiate administration. The election of his successor is fixed for the 3rd of November, and several candidates are declared as likely to compete for the position. Dr. Mapother, Professor of Physiology in the College, and a former Councillor, and Dr. Robert Smith, Professor of Surgery in Trinity College, have announced their candidature, and in addition to these, Dr. Darby, President of the Irish Medical Association, and Dr. Kirkpatrick, Medical Officer of the North Dublin Union, are mentioned as probable claimants.

Garibaldi's Areopagus.—Garibaldi proposes to unite the civilized world in one grand republic under the government of the great powers of America and Europe, with Nice for its capital, and for its constitution—1st. War between nations an impossibility ; 2nd. All differences to be referred to the Areopagus at Nice for pacific adjudication.

Cholera.—From Zanzibar this disease appears to have spread to other places. Mostly in the caravan routes.

Small-Pox.—We hear that this disease is prevalent at Heunslow, and some other places. In Paris it is said by a correspondent to be about the same as before the siege. Some papers say it prevails at Genoa, and in other Italian towns.

Scarlet Fever.—This disease still increases in London. A letter from Edinburgh speaks of an epidemic there also.

Registration of Disease, and Poor-law Medical Reform.—The following propositions have been submitted to the President of the Poor-law Board, by a deputation from the Poor-law Medical Officers' Association, and the British Medical Association. 1. That medical relief and the sanitary care of the poorer classes, with which the registration of disease is indissolubly connected, are questions which ought not to be treated independently of each other, and that they require to be settled on improved principles by a connected and consistent scheme of legislation. 2. That with regard to medical relief under the Poor-law, it is desirable to establish in England and Wales a system of district dispensaries, similar in many respects to that which has been for some years in operation in Ireland (of which a system of registration of disease forms an important part), with great benefit not only to the sick poor, but also to the public health and the control of pauperism ; and that in every district medicine and other remedial appliances be provided under inspection at the cost of the local authorities. 3. That in order to secure efficient treatment of the sick poor, and adequate remuneration to their medical attendants, it is important that the area and population of medical districts and the salaries of the medical officers be resettled as far as practicable on a uniform basis, by a code of regulations or general orders having statutory force ; no local exemptions being permitted without the sanction of the central authority. 4. That the position, the tenure of office, the qualifications, and the duties of the medical officers be determined and regulated by the same code of regulations, and that the salaries of the medical officers be paid either wholly out of the Consolidated Fund, or partly from that Fund, and partly from a county rate. 5. That a general registration of disease be instituted, and that all new cases of sickness, &c., coming under treatment at the public cost, whether in union districts and workhouses or in public and charitable institutions, be returned every week, or oftener in times of pestilence (according to a uniform system of nomenclature and record), by the resident medical officers of such institutions and by the Poor-law medical officer, who should be fairly remunerated for this addition to their labours. 6. That the above returns of disease be collected and revised by a registration medical officer, or by a medical officer of health, acting as such in every superintendent registrar's district or group of districts, so as to constitute a register for the use of the local authorities, and that a copy thereof be forwarded at stated intervals to the central authority. 7. That certain preventive duties be performed by the Poor-law medical officers as deputy health officers, and that they be paid for such sanitary duties, on a scale to be determined, by the central authority. 8. That in order to rectify and prevent abuses, the medical and sanitary care of the poor in districts and workhouses be subjected to periodical inspection, either by the proposed chief officers of health debarred from private practice, or by medical inspectors under the central authority, or by both. 9. That in any re-arrangement of our sanitary organisation, resulting from the inquiry of the Royal Sanitary Commission, it is desirable that the foregoing propositions be embodied.

The King and Queen's College of Physicians in Ireland.—At the annual stated meeting, held on the 18th instant, the following officers were elected for the ensuing year :—President—Dr. Banks ; Censors—Dr. Gordon, V.P., Dr. Ringland, Dr. Hayden, Dr. Walter Smith ; Treasurer—Dr. Dwyer ; Examiners in Midwifery—Dr. Atthill, Dr. Johnston ; Professor of Medical Jurisprudence—Mr. Robert Travers ; Registrar—Dr. James Little.

Royal College of Surgeons of England.—The following is an abstract of the unconfirmed minutes of the last meeting of the Council of the College, on the 13th instant :—The Secretary was directed to inform Mr. Edwin Lowe of his removal from being a Member, owing to his having been convicted of felony, and to call upon him to return his diploma, as required by the by-laws, and, in compliance with the requirements of the Medical Act, to inform Dr. Hawkins of the fact.—A letter was read from Mr. E. Deas-Thomson, thanking the Council for the recognition of the Sydney Infirmary and Medical School ; whereupon a protest was read from Fellows and Members residing in Sydney against the recognition of such institution. The document was referred to the Court of Examiners for consideration.—A memorial was read from Mr. Thomas Monk, late Mayor of Preston, removed in 1858 from being a Member, in consequence of his having been convicted of forgery, and requesting to be restored to the Membership of the College. An answer was ordered to be sent, stating that the Council had not the power to entertain the request. —Letters were read from Sir William Fergusson, Bart., the President of the College, and Mr. Quain resigning their appointments as examiners, and from Mr. Skey declining again

to be put in nomination for the office of examiner; a letter from Mr. Curling was also read, declining, for reasons stated by him, at present to be put in nomination for the office of member of the Court of Examiners.—The following Fellows of the College were nominated for the office of examiner:—Messrs. G. V. Ellis and J. Marshall, of University College; Messrs. W. S. Savory, G. W. Callender, and H. Power, of St. Bartholomew's Hospital; Mr. Timothy Holmes, of St. George's Hospital; and Mr. J. Hutchinson, of the London Hospital. The President explained that, in accordance with the charter and by-laws, the choice of the Council would not be restricted to the Fellows nominated.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

We must also request our Correspondents to write only on one side of the paper and in *legible* characters. We are often compelled to consign MSS. to the waste-paper-basket merely because it is illegible.

Correspondents not answered in the current Number are requested to look to the Notices the following week.

A Traveller.—We recommend *Punch's* statement to you as follows:—"The climate of Madagascar has lately been subjected to a searching chemical analysis by three of the first physicians of the day; the result is most gratifying to every well-wisher of humanity. It is composed of unequal parts of oxygen, ozone, common salt, and the breath of popular app ause, and may be had in bottles for exportation."

Disinfectant.—Mr. Gamgee's new preparation is called chloralum, to distinguish it from chloral (hydrate), it is now proposed to write it as it is pronounced, chlor-alum. It might as well have been called alumchlor.

An Occasional Reader.—If you were a regular reader you would not need the information. The questions have been more thoroughly discussed in our colums than in any periodical.

Mr Brooks.—Our "Student's Number" may be obtained by you in Dublin at Messrs. Moffat, 6 D'Olier street.

G.—The *Medical Temperance Journal* is published by Tweedie, 337 Strand. The article you referred to from us appeared in their April Number, page 140.

Placebo.—Thanks. Your communications and everything coming from you will receive our attention.

MacMahon's Wound.—Will our Correspondent, just returned from Sedan, who writes to us on the Marshal's wound, be good enough to call at our London office if still in town.

C. G. A., Trowbridge.—The work is by Dr. Thudichum. He it is who talks about "Natural Tea-wine."

Dr. A.—With pleasure; but to ensure early insertion be brief, since the topic has been discussed already.

M.D., Manchester.—Accept our best thanks. The Press goes to the gentleman in the future you name. We want more friends like you to get us new subscribers in the Provioces.

Dr. Smith.—The coroner had no right to ignore medical testimony in the case. Write at once to the Home Secretary and obtain an order for exhuming the body and re-investigating the case, which must be through the coroner if he be not superseded.

Dr. Hind.—The case would probably be interesting.

J. G.—The paper has already appeared.

Clinical.—See our "Current Topics" last week.

A. J.—The extracts or abstracts would be inserted if sent.

Dr. Wakley.—The specimen sent has been subjected to careful analysis, and is found to be pure.

Juvenis.—We do not prescribe; consult your family attendant.

To the Editor of "The Medical Press and Circular."

Sir,—Having seen in your issue of October 12th, an account of a "Respirator invented by Dr. Waring-Curran," would you kindly inform me where such may be obtained, and its cost.

I am, your obedient Servant,
L.R.C.S.I., L.Q. and Q. Coll. Phys.

To the Editor of "The Medical Press and Circular."

Sir,—The Medical Officer's Superannuation Bill is hardly worthy of the name; left at the discretion of the Guardians (carried in the House by a majority of a 101), just like a poor man whose labour is done—and past age—applies for relief, and is probably, after a good deal of hemming, &c., granted 2/6 per week. This could never have been the meaning of Dr. Brady's Superannuation Bill!! to lower a man to such a status. Do endeavour to remedy this evil by your widely circulated Journal.

I am, dear Sir,
Your very obedient Servant.
October 19th, 1870. A Constant Reader.

The London Societies.—The following are the times of Meeting and the Papers announced to be read during the ensuing week:—

Hunterian, at 8 P.M., Wednesday 26th—Adjourned discussion on Mr. Bryant's Paper, "On Pyæmia."

Clinical, at 8½ P.M., Friday 28th—Dr. Sutton, "On two Cases of Scurvy," and Mr. Carter, "On Cases of Optic Neuritis."

Queckett Microscopical, at 8 P.M.—"On the Microscopical characters of Cannel Coal." by Mr. Slade.

Medical, at 8 P.M., Monday 31st.—Ordinary Meeting.

Pathological, at 8 P.M., Tuesday, November 1st.—Ordinary Meeting.

Received from Dr. Luther, communications "Upon the Use of Aconite in Loss of Voice, and in Veterinary Medicine." Dr. Francis McEvoy, "Case of Fracture of Thigh, with Punctured Bladder Recovery."

VACANCIES.

Bradford Infirmary.—Resident Medical Officer. Salary £100, with board.

Morpeth Dispensary.—House-Surgeon. Salary £100, with residence.

Eastern Dispensary, London.—Resident Medical Officer. Salary £100, with residence.

APPOINTMENTS.

Anderson, J., L.R.C.P.Ed., Surgeon to the Inveraray Prison.

Ashe, Isaac, M.B. and C.M., Trin. Coll., Dub., Consulting and Visiting Physician to the Donegal Lunatic Asylum, Letterkenny.

Bellis, E., L.K.Q.C.P.I., L.R.C.S.I., Demonstrator of Anatomy in the Ledwich School of Medicine, Dublin.

Cumberbatch, E., Mr. A. J. Hogg, Mr. P. B. Stoney, and Mr. A. Young, House-Surgeons to St. Bartholomew's Hospital.

Dunlop, W., L.R.C.P.Ed., Medical Officer to the Letterkenny Union.

Fiddes, David, M.D., Augus Fraser, M.D., and John R. Traill, M.D., Examiners for Gradation in Medicine at the University of Aberdeen.

Goude, H., Resident Obstetric Assistant at St. Bartholomew's Hospital.

Greene, R., L.R.C.P.Ed., Assistant Medical Officer to the Sussex Lunatic Asylum.

Ilott, J. J., Resident Medical Officer at the Whitechapel Union Workhouse.

Lloyd, A. E., M.R.C.S., House-Surgeon to the North Riding Infirmary.

Merson, J., A.M. C.M., M.B., Assistant Medical Officer at the Northumberland Lunatic Asylum, Cottingwood, Morpeth.

Norton, G. E., M.R.C.S., Chloroformist to the Middlesex Hospital.

Owen, A. L., B.A., Medical Officer to the Royal Portsmouth Hospital.

Richmond, Sylvester, M.D., M.R.C.S., Surgeon to the Northallerton Gaol.

Marriages.

Sinclair—Hamilton.—On the 1st ult., at Simla (from the house of Staff Surgeon T. M. Bleckly, M.A., M.D., LL.B., brother-in-law of the bride), Surgeon Ed. W. M. Sinclair, 20th Brigade Royal Artillery, to Anna Catherine, daughter of Andrew Hamilton, Esq., Dublin.

Smith—Hope.—On the 19th inst., at All Saints, Knightsbridge, Heywood Smith, M.A., M.B., of Portugal street, Grosvenor square, son of Dr. Protheroe Smith, to Emily Anne Gertrude, third daughter of the late Lieut. the Hon. James Hope and Lady Mary Hope.

Birth.

Clarke.—On the 18th of September, at Well Park, Oughterard, Galway, the wife of F. E. Clarke, M.B., of a son.

Deaths.

Coleman.—On the 11th inst., at Carlsruhe, Germany, Wm. St. John Coleman, L.R.C.P.Ed., of Miltown-Malbay, Co. Clare, aged 29.

Dawson.—On the 11th inst., at Portobello, Wm. O. Dawson, L.R.C.P.

Dewar.—On the 12th inst., at Little Dene, Burntisland, Andrew Dewar, L.R.C.S.Ed., late of Dunfermline, aged 78.

Henderson.—On the 13th inst., Wm. Henderson, M.D., of Rose terrace, Perth, aged 86.

Hughes.—On the 6th ult., at Corwen, W. E. Hughes, M.R.C.S., aged 32.

Paley.—On the 19th inst., at Addison Gerdens, North Kensington, James Paley, M.D., in the 52nd year of his age.

The Professional Calendar;

OR, WEEKLY REGISTER FOR GENTLEMEN REQUIRING ASSISTANTS, AND FOR ASSISTANTS SEEKING APPOINTMENTS.

A Qualified Surgeon and Accoucheur wants a Situation. Salary not so much an object as a comfortable home; good references.—Address, V. A., Medical, "General Advertiser," Dublin.

An Assistant, of long experience in Compounding and Medical Hall Practice, is open to an engagement; no objection to the country; excellent reference and testimonials.—Address, V. B. R., Medical, "General Advertiser" Office, Dublin.

Wanted, an Out-door qualified Assistant. Salary £100 per annum, with furnished apartments, gas, coal, and attendance. Must be able to speak Welsh.—Apply, E. J., Ty-mawr, Aberdare.

Wanted, by a Practitioner in China, a fully qualified Gentleman, to Assist in the Practice, on terms which may be learnt by application to Dakin Brothers, 2 and 3, Creechurch lane, Leadenhall street, London.

Wanted, an Out-door Assistant, to keep the books, dispense, visit, and attend midwifery. He must not be under 26 years of age, able to ride, and produce unexceptionable testimonials.—Apply, A. B., Post-office, Atherstone.

Wanted, by the Advertiser, aged 30, single, sine diploma, a Re-engagement as Out-door Assistant. Satisfactory references London or a town preferred. Address, Alpha M., General Post office, Halifax, Yorkshire.

The Medical Press & Circular.

FEIGNED INSANITY.

By J. H. BALFOUR-BROWNE, Esq., Barrister-at-Law.

(*Continued from page* 303.)

4. *Mania.*—There is a method in all madness! But the method which is in mania, and is the result of the regular laws of unhealthy action, differs widely from the method which is imposed upon the incoherence of simulated madness by thought. The very close observation of mental disease by one of a sufficiently powerful intellect thoroughly to understand and appreciate its manifestations, might lead to such a deceptive reproduction of a number of symptoms as to puzzle many individuals, not trained to distinguish between very fine shades of expression, as indicative of varying springs of action. And the tendency which the human mind has to make real and earnest what may be begun in fun and frolic, or may be undertaken with the sole object of deceiving, is one thing which tends to complicate the investigation. Good acting will often give a shape to life. The story is told of Mrs. Siddons, that on one occasion after a successful representation of *Lady Macbeth*, she was found wandering about the passages which lie beneath and behind the stage, wringing her hands and muttering, "I can't get out,"—so does the ideal become the real! It is the history of the making of all things!

But it is to be remembered that those who have occasion to feign insanity are not those who are qualified to give a faithful representation of the whole life of an individual under the influence of mental disease, and that their opportunities have not been such as to enable them to become intimately acquainted with the whole of the manifestations of the abnormal state. And, owing to these circumstances, the difficulty of feigning insanity so as to deceive a physician well acquainted with the disease, is very great, so great, indeed, that Dr. Conolly affirms—"That he can hardly imagine a case which would be proof against an efficient system of observation."*

One observation which is of practical importance to those who are desirous of distinguishing the real from the imitated form of the disease is, that what the knowledge of the impostor lacks in extent, he invariably tries to compensate by the intensity of his acting. He over-acts the few symptoms with which he is familiar, while he neglects many other symptoms that have considerable diagnostic value. Where, therefore, a considerable exacerbation of prominent symptoms occurs, in conjunction with the absence of less easily observed manifestations, it gives, at least, a high probability of imposture. Where, also, there is considerable variation of the symptoms in the presence of different individuals—*ex. gr.*, where in the presence of a medical man, known to be such, the symptoms are more carefully produced, while in the presence of others they are produced in such a rough-hewn shape, as is calculated to carry, through a witness, to the medical man, the presumption is in favour of feigning. In most cases effort can be detected in all the assumed ravings—the effort of argument, for it is always the impostor's desire to prove to persons, who are present, and may be observers, that he is really mad; and, owing to this circumstance, the endeavour is not unlikely to fail: for persons really insane are, not unfrequently, in the presence of a stranger, calmer and quieter than at other times. There is always some assertion in the ravings of one who only feigns insanity. The manifestations are all prominent. Many discrepancies are to be found in assumed insanity. Mania is, really, the brain working under such high pressure that its ordinary action is interfered with. But there is no dulling of any of the faculties. Friends are almost invariably recognised; names, dates, occurrences, and places are remembered. The senses seem to be somewhat more acute than they were in times past. The impostor not unfrequently endeavours to make assurance doubly sure, and introduces a few symptoms of dementia into the stratagem, and so he is discovered! In simulated insanity, the memory is often found to be defective: recent events with which the individual has been connected seem to be entirely forgotten, the impression of the malingerer being that silence is a stronghold. The real maniac almost invariably remembers all the events with which he was con-

* "Inquiry concerning the Indications of Insanity." P 467.

cerned, although his disease may cause considerable distortion of some of the facts. Through the madman's delusions and their manifestations there runs a thread, which gives a sort of order and method even to the chaos of his thought; through the manifestations of him who would feign insanity this order is wanting. It is like the difference between a building which time, even while she beautified from her rouge pot, with lichens, tears down with slow inexorable fingers, and a building which the malice of mankind has razed to the ground and left not one stone upon another. The one has the order which a God-made chaos must have; it is pregnant with an order which will be born—the other is a chaos aforethought!

In the vagaries of the madman, there is one invariable recurrence to the main drift of the delusion; in the impostor's delusions there is an increasing changeableness. There is an earnestness in the madman; he believes what he says for the most part. The earnestness in the man who imitates is only to produce a certain impression upon his audience. He has no affection for the shape of his delusion; he will alter it much and often to bring it more nearly to correspond with what he considers best suited to attain the end he has in view. In most cases a careful observer might trace a distinction corresponding to the above explanation in the mode of manifestation. The one —whose delusions are objectless—whose erroneous beliefs are ends in themselves, is unhesitating in their expression, his utterance is usually rapid, and his incoherence trips merrily from his tongue. The other, whose delusions are buoys to which he clings to save him from the waves of circumstance, whose erroneous beliefs are means to an end, takes time, he has to consider whether this will do under the circumstances; his style differs from that of the real madman, he hesitates, and his incoherence has the appearance of being studied. All these circumstances are calculated to show where certain manifestations have their roots —in the sad truth, disease—where in the sad untruth, a lie.

Not unfrequently much light will be thrown on the question of feigned or unfeigned (?) by the state of the affections and desires of the individual. Every thought a man thinks is shaped and fashioned in a mould of feeling. Thought is, as it were, the shape of a vessel; and feeling, as it were, the figuring and embossing, or painting, of the same. Thought, the skeleton; and feelings, the flesh and blood of a body. Now, in mania many of the most prominent features which marked the character are lost. As magicians could change gold to lead, so does this magician —disease—change love to hatred. Very often those persons that were loved best, while the individual was in health, are hated worst, when the individual is diseased. If suspicion is on the wing it alights upon some intimate friend, or near relation—home ties seem changed from blessings to curses; and a former affection seems to be reason good for hostility and war. There is no more promising symptom of a remission of the disease than a return of the rivers of the heart to their old courses. The man, who would feign insanity, invariably shows much animosity, but it is usually directed not against those who love him, and now weep for him; he sees disadvantage in alienating affection, so his wrath is directed against some one who formerly injured him. If the madman has a delusion concerning a conspiracy, his wife, or children, or friends, will be looked upon as the conspirators, and loathed in consequence. If the same man sees reason to feign such a delusion, other persons will usually be regarded in the light of his persecutors. But, not merely are the affections diverted from their objects in mania, but many things cut into a man's heart by habit seem to be erased. A man or woman of the most scrupulously, pure, and refined habits will, under the influence of this disease, become insensible to the common decencies of life. Words and actions utterly strange to the individual's whole life and character, are the ordinary expressions of their insane vitality. All those actions which are most filthy and horrible have been, and will be again and again, made use of with the view of inducing a belief in the genuiness of assumed insanity; but the entire change of character under the influence of the disease from what it was in health, is not likely to be counterfeited. It is said that in mania the pulse is usually more frequent than in health; but although it is reported that, owing to this circumstance alone Dr. Rush was convinced of the unfeignedness of the insanity in a certain case, we would not be inclined to place implicit reliance upon this symptom. The sphymograph might write a man down an impostor. We have already in another connection alluded to the importance of physiognomical diagnosis, and we would only add that each disease has a distinct face-symptom, an invariable type of expression, running through the transient shades which are dependant upon an ever varying train of thought. The impostor can't really feign that. In mania, too, there is generally discoverable a slight febrile action, and a peculiar odour of the skin. The want of sleep is a symptom which is useful in the diagnosis of genuine mania. The impostor cannot stave off that enemy long. His exertions and feigned excitement, and the anxiety as to the success of his scheme, all weary him, and after a day or two at most, he will fall into a deep quiet sleep. The maniac on the other hand passes days, and sometimes weeks, without any apparent necessity for sleep; and when sleep does come it is restless and unhealthy sleep. The shutting of the doors of sense allows you to look into the heart, as it were. The restlessness of health with a purpose, is very easily distinguished from the purposeless and animal-like motions of disease. The madman will show the same indifference with regard to food that he does with regard to sleep; the appetite of the sane man will often betray him. The insensibility of individuals labouring under mania to certain drugs, such as opium, is a test of some value. The dose which would send an impostor to sleep, however determined to resist its influence, would have little or no effect upon a person really suffering from this disease. The same remark applies to certain other medicines, as purgatives and emetics. It requires a larger dose of tartar emetic to produce its depressant effects upon a madman than it does upon a sane person. But not only is the body insensible to the ordinary effects of certain drugs, but some of the senses appear to be insensible in such a high degree to the ordinary effects of over-simulation. It is said that the madman can, eagle-like, look full in the sun's face, and thus insensibility, in certain cases, to cold, is a well-marked peculiarity.

The genesis of mania ought, in all doubtful cases, to be carefully inquired into. The preliminary symptoms of a genuine attack of mania are not likely to be simulated. Feigned mania begins suddenly! Where the insanity is real, many instances of strange and, at the time, unaccountable conduct will be remembered. The inquiry as to the occurrence of the disease, should also extend to circumstances which might have predisposed to its invasion. The habits of the individual, the health or disease of other members of the family, the inherited or acquired peculiarities of constitutions, the previous tendencies of the individual to the disease, the temperament of the individual and the moral and physical circumstances which surround him should be made the subject of diligent and intelligent inquiry. The irritability of temper of the real maniac differs from the grand showy outbursts of the impostor. This is, however, a symptom of less importance, and it is somewhat easy of imitation. The periodicity of the attacks which has been remarked in real mania, will not occur in the feigned disease.

5. *Partial Intellectual Mania—Monomania—Melancholia.*—It is much more difficult to feign partial insanity, than to feign what is called mania. In proportion to the difficulty is the rarity with which it is simulated. In partial intellectual mania, many of the symptoms are present, which characterize the general disease, yet in most cases they are not so obtrusive, and a more careful examination

has to be conducted, before the fact of the insanity discloses itself.

Epilepsy can be, and is feigned. Beggars live by fits, and one detected in the act, confessed that he had been taught the trick by his father, who studied the symptoms in a book.* Would there, we wonder, be primogeniture in the property in a fit? would it go to the heir or next of kin. A case of well simulated epilepsy is mentioned in Legrand de Saulle.† To show that there is sometimes a difficulty in distinguishing between the simulated attack and the real disease, we may mention a case that came under the notice of Esquirol, who during one of those conferences, which took place during the clinique, boasted, that no cunning could deceive his power of diagnosing a case of assumed epilepsy. One of the pupils shortly afterwards fell suddenly, was convulsed and presented all the other symptoms of severe epilepsy. Esquirol, watching with deep anxiety, turned to those around saying, "Ah, poor boy, he is an epileptic." The boy sprang to his feet crying, "You see, my master, that we *can* simulate an attack of epilepsy."‡ That simulator was Calmiel, the greatest authority upon general paralysis, and still, although old, the physician of Charenton. Sailors who prefer deck-work to going aloft often feign epilepsy. An examination of the hands during the seizure will generally show whether it is real or not. The thumb of the real epileptic, is invariably held down into the palm by the other fingers. A practised ear ought to be able to distinguish the cry which, upon all occasions, accompanies the seizure. Occasionally, pretended epilepsy has passed into, or been merged in the real.‖ Many acts which have been planned by, will pass out of the domain of will. You can make a habit, but it masters you when it is made. It has been asserted with some reason, that the marvellous power which some insane persons have of simulating diseases may be due, not only to the perversion of muscular volition obtained by habitual exercise, but also to an exaltation of the powers of co-ordination due to the diseased condition.

The same prejudices, however, have possession of the mind, the same irritability of temper, the same unfounded likings and dislikings, affections and aversions, the same sleepless restlessness and insensibility to impression, and the operations of drugs, are to be found in this form of disease. The pretended monomaniac, will, however, parade those symptoms, while in the individual really suffering from partial mania, there will be a tendency and effort to conceal them from observation. He is generally quiet and reserved, but will become querulous, and sometimes violent in an argument. "A real monomaniac" says Marc, "is strongly prejudiced in favour of his opinions, the slightest contradiction excites his temper; while the simulator readily overlooks this essential point in his part, if the contradiction is skilfully managed. The taciturnity peculiar to the real subjects of monomania, frequently leaves simulators at fault, since the complaints of the latter were sure of being seen and heard, and their repugnance at dwelling in solicitude, are not met with, or at least not in the same degree in the others."

The forms of intellectual insanity in which it is most difficult to distinguish the real from the feigned, are those which are manifested by profound melancholy, or the possession by the mind of one fixed delusion! Here it is evident, that the marks of effort, of planned disorder, of occasional signs of healthy mental action and ordinary human interests, will not suffice as marks by which to know the true from the false. In many of the forms of partial intellectual mania, as we have before shown, irresponsibility should not be admitted, and in cases in which the delusion was connected with the crime of which the individual is accused, or where the melancholy is so profound, as to deprive the accused of any power of choice; in such cases a careful observation by medical men, extending over a considerable portion of time, with a view of marking the progress, which the disease—if unfeigned—will make in one direction or another, would not fail to discover an artifice, if it exists, or to establish the fact of real disease. In all cases the family and individual history, if it can be ascertained, will afford some presumption, which will be of use in the investigation.

In moral mania, which according to Hoffbaur "may exist uncomplicated with mental delusion, and is in fact, only a kind of mental exaltation (tollheit), a state in which the reason has lost its empire over the passions and actions by which they are manifested to such a degree, that the individual can neither express the former, nor abstain from the latter." In this kind of insanity, where the chief ground for believing in the existence of mental unsoundness, is the character of the acts committed, and very often nothing more than the character of the single act, of which the criminal is accused, the difficulty of distinguishing what is real from what is feigned, is exceedingly great. Up to the present time, courts of law have been very unwilling to admit moral mania, as proved only by the quality of the act of which the individual is accused, as a good plea in criminal cases. And it has done so upon what seems good grounds. That a criminal act may be the first symptom of insanity is true, but that the brutal quality of the act, should be admitted as sufficient proof, that it resulted from an insane impulse is absurd. The science of evidence may be superseded in time to come, but while it is still looked upon as a science, and still regarded as the only guide in the decision of all questions of criminality and responsibility, not to say, what would be true, all questions in life, to allow the act itself, with which an individual is charged, to be an all sufficient proof of the insanity of the accused is impossible. It may be true that the man is mad, as in many other cases it is true fatal blows have been struck in self-defence, but as in the latter case, if the self-defence could not be proved by facts other than the deed, so in the former case, the insanity cannot for a moment be permitted to be proved by the atrocity of the crime alone. The result of the admission of such a doctrine would be to add to the atrocity of every crime. And an individual who wished to commit murder on a neighbour, would, to secure his immunity from punishment, cut a few more throats. It is, however, in many cases, unlikely from other circumstances, that a sane man could commit a crime without any motive; it is certain that no sane man does anything without a motive, and although the motive may not be good, it is invariably rational. Where therefore these circumstances can be, and are brought out, as in a case where an individual in a good position in society, in circumstances which would lead most men to live easily contented suddenly kills another, never having seen him nor communicated with him before, by whose death he is in no way advantaged, and from the consequences of whose death, he sees no probability of escape; in such a case, even although there may be no delusion, the presumption of insanity is very strong, and upon suitable medical testimony the individual ought to be held irresponsible. Such cases, however, will not fall under the notice of him who is studying feigned insanity, and if capability of judging of motive is looked at as the only guide in deciding all questions of responsibility, although an occasional error may be committed as in all other inquiries—few persons will escape from punishment by simulating moral mania, unless they are very vigorously seconded in their efforts, by injudicious medical gentlemen.

ON THE TREATMENT OF DELIRIUM TREMENS.

By Dr. Ludwig Meyer, of Berlin.

(Translated specially for the Medical Press and Circular from the German, with a few Practical Observations added, by Dr. Thomas Bodkin, F.R.C.S., &c.)

Whilst the treatment of internal diseases has almost every where assumed a milder form, and the physicians of the so-called expectant method have acquired a greater range of influence, yet the more defined and intense, the more typical the form of disease manifests itself, so have the therapeutics of delirium tremens acquired up to the present day a heroism almost undisputed, as fresh and hopeful as is remembered of the olden physicians. The data connected with so energetic a medication will be more conceivable when the grounds of their first introduction are inquired into. The first diagnostic of delirium tremens developed itself on account of the injurious results that a yet old method of treatment had given rise to, it was in fact "a diagnosis ex nocentibus."

An apothecary in Kent, called Sutton, in the beginning of the present century, made the observation that a certain form of phrensey or phrenitis, which, with a grammatical exactness was treated with blood-letting, resulting almost invariably in the death of the patient, and that the few who happened to have survived, were those who happened to have slept. He gave up thenceforward, on account of the result, blood-letting, and took to opium, and Sutton had then connected with this method of treatment the required symptomatology and etiology; but the dependence of delirium tremens on alcoholism, was first forty years since generally known. The exclusive dominion of opium suffered, under the advocates of contra-stimulants, some damage. Barkhausen, second physician to the Bremer hospital, in 1828, more fully systematized the therapeutics of delirium tremens, indicating in the sthenic form the administration of tarter emetic, and in the asthenic, different form, opium. Later, instead of the tartar emetic according to Rademarcus's proposition, suggested by Wolf, the acetate of zinc was substituted and adopted in the Berlin Charity. This mode of treatment I retained in the Special and General Hospital, from October 1858 to the end of 1859, while an assistant to the lunatic asylum during the summer months, into which cases of delirium tremens were received for treatment, and also in the Catholic Hospital. The trials which were practiced in the Berlin Hospital, chloroform, tincture of digitalis in large doses (half-an-ounce), recommended by the English physicians, turned out so unfortunately, that, notwithstanding the support of such a number of authorities, it was given up. The numerous observations afforded by a considerable number of *post-mortem* examinations led to the conviction established—that delirium tremens is not of the nature of a violent acute condition peculiar to itself. Delirium tremens is partly, as far as is conceived, a manifestation of a not well understood condition, a peculiar exacerbation of chronic alcoholism, of a not to be mistaken typical development. If on the other hand there be present a chronic illness, a continuous degenerative process, engrafted on the constitution. The treatment hitherto pursued in delirium tremens may not be recommended, so it appears even contra-indicated on account of the tendency in every case towards collapse, which is the chief, indeed, exclusive danger to life. The generally small persistently wavering and often imperceptibility of the pulse; the quick alternating flushing and paleness; the profuse—the sudden cold clammy sweat; alternating placidness and dryness of skin; above all, the extremely severe seizures of epilepsy point out a threatning anæmia of brain, which is observed to be the next most frequently cause of death. It is certainly allowable to depart from a medication which, according to all rational supposition, was most calculated to increase the symptoms of impending danger.

Since the year 1860 a new practice has been introduced, the indication of a more vigorous diet, arising out of the suggested necessity of supporting the patient during the short duration of the stormy attack, thus supporting the strength notwithstanding the state of the pulse, and suiting the desire and inclination of the patient; therefore, light nourishment in the first instance, plentifully administered bouillon, milk and occasionally diluted wine (evunsuppe) to preserve the strength. If this suggested nourishment was insufficient, and symptoms of collapse advanced, port wine, but still in a dilute form, a table-spoonful to a glass of water, or selzter water, the extreme dilutions were better borne than pure wine, and lasted much longer in their effects, accordingly the doses were given three or four times daily or every intermediate hour, seldom at shorter intervals. In isolated instances, according to the existing symptoms, Portio Revire, mistura acidi sulph: mist. ammon.: and the like, occasionally warm chamomile stupes to the head, to the stomach, at the same time wine was ordered it not contra-indicated by the progress of the case; but as all most essential means were carried out, mechanical restraint was carefully avoided, mechanical restraint always acted as an incentive to resistance and quickly exhausted the strength of the patient. The inevitable effect of the strait waistcoat and poitral, which hindered the important motion of breathing; had it been necessary to restrain the patient in the severe surgical cases so was it the more necessary to have additional assistance at hand, the changing of position should be effected with the least possible force, and be done with the least possible delay.

Up to this time, about 500 accurately reported cases of delirium tremens treated in the General Hamburg Hospital, as the following statistical view will show, with a result as opposed to the old method of treatment must be observed to be exceedingly favourable, the mortality being three times less. It is of course already known that a different treatment in dangerous variations of delirium tremens should be adopted as suggested by Laycock of Edinburgh in the *Edinburgh Journal*, 1862. But hitherto the results of a more expectant method have occurred in too small a number of cases, so that the noticing of them would serve to little purpose. The facts of more extended observations, are wanting on exact data in the progress of delirium tremens over a greater space of time, yearly if possible. The distribution of cases noted during the extent of one year is most dissimilar, eight or fourteen days may elapse, sometimes a whole month, without a single case being presented for reception, whilst at other times the average proportion of a month is distributed over a few days. I could not discover a sufficient cause for this remarkable vicissitude, or the simultaneous cessation or existence, other than an outbreak of delirium tremens at a predisposing time, with the exception of traumatic cases, so that therefore, one is probably inclined to grant in the occurrence of the disease a certain epidemic element; there is, besides, in the mortality of this small epidemic a strange difference, while a very considerable number of cases occurred in succession without a single death; on another occasion, from one-third to one-half died, this higher mortality stood in no direct relation, with a relative intensity of the several cases, no regular proportion between the distribution of the latter, and the mortality was found to exist.

Thirteen per cent. died out of those cases which were received in the year 1861; this is the greatest mortality observed under any method of treatment—double as great as in the following years, although the number of severe complications, fractures, and pneumonia, fell off to almost less than other years. The proportion of mortality of delirium tremens, under the old method of treatment as shown by the statistics of the large hospitals, differ not much from each other. At Copenhagen, in Frederick's Hospital, either 54 or 30 per cent. out of 178 cases of delirium tremens died (Lend du del. trem.). In the Royal Infirmary of Edinburgh, 126 out of 481 died, or at the

rate of 26 per cent. (*Edinburgh Monthly Journal*, 1862). In the Berlin Charity Hospital, 25 per cent. (*Annal der Charatee*, 1861.)

The favourable influence of the new method of treatment is placed in a clear light as may be seen in the adjoining table; the complicated distinguished from the uncomplicated is made evident. It therefore appears that the greatest proportion of fatal cases near two-thirds in calculating these more dangerous and absolutely fatal complications is made apparent, whilst the mortality of the uncomplicated cases scarcely exceeds two per cent., against six per cent. of the old method of treatment.

A fatal case of delirium tremens having lately occurred in my neighbourhood, the particulars of which I am not in a position to publish, has recalled my attention to the above article taken from the *Berlin Khlinische Wokenschrift*, read before the Society for Natural Philosophy and Medicine of Hanover by Dr. Ludwig Meyer.

Having had occasion to treat, during a period of upwards of thirty years, an amount of cases of delirium tremens, as much perhaps as falls to the lot of many, I may be allowed to venture on a few practical words on the subject.

The history, etiology, and pathology of delirium tremens is so thoroughly and exhaustively given in Copland's incomparable "Medical Dictionary," now twenty-six years since published, that nothing, I believe, is required to be added to that part of the subject. A graphic description of the symptoms, by Pliny Earl, M.D., of New York, although a little sensational, nevertheless true on the whole, will be found in the Medical Press (Vol. 19, No. 495, page 415, for June 1848); but the therapeutics of delirium tremens have since enjoyed a more extended and modified range. Opium is not now so exclusively relied on, nor is it given in such reckless and heroic doses, and although not entirely dispensed with, it is seldom used except sparingly and with caution. Need I say that to procure sleep by all fair means, without which, in delirium tremens, death is inevitable, is the one consummation to be sought for, and, of course, should occupy almost the exclusive attention of the medical attendant, inasmuch as when sound sleep sets in the doctor's triumph is secured —his patient from that moment is safe. The means to this happy end would, I presume, be threefold, all co-operating to induce sleep—viz., moral, dietetic, and medicinal. To carry out the first, not the least important, requires some sagacity and ingenuity in dealing with the morbidly excited, and the newly acquired eccentricity, of the patient's mind. His optical delusions being his convictions—if controverted or contradicted, causes increased excitement, angry and stormy opposition, he acts as if insulted, and is annoyed to have his veracity questioned; better to divert him by some topic foreign to his present expressed thoughts, such as presenting to his mind some pleasing former events of his life, to flatter his self esteem, to pretend to be his friend and his advocate in defending him against those whom he supposes frustrate his wishes, and who he angrily alleges are giving him such annoyance, and against whom he inveighs with bitterness and denunciations. By carrying out these suggestions, or the like, according to the morbid temper and peculiar tendencies of the patient's mind, a complete control will be acquired over him, so that he may be led like a child, and will almost do anything he may be required. On the question of physical restraint, I believe that Dr. Meyer is quite right. I have no doubt that death has been the result of physical restraint in many cases I am myself aware of an instance of a patient dying in the midst of his furious struggles, while tied down to his bed with ropes, and while guarded by police, and feel convinced he would have had more than a fair chance of his life had he been set at liberty, and allowed to walk out into the open air, accompanied with a steady attendant, a wish he so furiously struggled to accomplish, and which cost him his life in the refusal. When somewhat tired by the walk, and cooled down by the open fresh air and satisfied that he accomplished his desire, I have no doubt he would have retired in peace to his bed, would probably sleep with the aid of some slight hypnotic; such a happy result has frequently occurred to patients of mine with whom I have walked through the town even at the dead hour of night liberating my patient in a state of storming passion from the restraint of his keepers, and returning in an hour with him metamorphosed into a man of peace, like a lamb perfectly obedient to my wishes; a game of cards, if the patient is

so disposed or accustomed to play, I have found on several occasions, acts most surprisingly in dissipating optical illusions and calming excitement; at first sight, such a suggestion may appear ridiculous, nevertheless, it has frequently succeeded with me, and it would appear incredible to suppose that a game of cards could be so well, so attentively, and so cautiously played by a patient in such a state of mind, however, such is the fact. Although I have suggested, as a general rule, the advantage of allowing patients in delirium tremens to walk in the open air, yet exceptions in certain cases with extreme debility sufficiently characteristic occur, such as has happened in a case of mine a few years since, the man was strong built, aged about forty, he was daily drunk for a fortnight, I saw him six or seven days after the attack, he was jaundiced, his liver enlarged, his abdomen swelled, doughy, somewhat tense, intelligence quite confused, incapable of recognising acquaintances, countenance foolish tremor, pulse rapid and small. I emphatically ordered that he should on no account be allowed to leave his bed for a moment, that if he did so he would very probably drop dead; notwithstanding my strict injunctions, in my absence an attempt was made to remove him to another residence some hundreds of yards off in an inside car; he fell dead in the car when he was a few yards on his way.

It is scarcely necessary to allude to the dietetic treatment, the indications for carrying it out are so simple. I will only say that I have always given in every case more or less stimulants, even in cases arising from a recent debauch, whatever was the state of the pulse, convinced that the strength in these cases is more apparent than real. The living almost exclusively without food on stimulants for a lengthened period before the attack would assure the certainty of debility concealed under the excited state of the patient. Now, with regard to medicine, the indications, in my opinion, are just as simple, if the bowels are too free by all means astringe them, a tea-spoonful of the tincture of rhatany repeated occasionally with a little port wine and water generally succeeds; if confined, ten or twelve grains of calomel always answered my purpose; if slow in its action after five or six hours, a table-spoonful of castor-oil may be given, not otherwise. To procure sleep I have seldom for many years found it necessary to give opium in any shape, if I see the patient early and find him not much the worse for the want of sleep, that he takes sufficiency of food, his pulse in fair tone, I leave him, perhaps, for two or three nights without any artificial means to procure sleep, by so doing I have frequently found patients when sufficiently tired out, sleep naturally without artificial aid; if there is epileptic tendencies, a not unfrequent occurrence, the bromide of potassium in thirty grain doses with twenty minims of tincture of Indian Mixture in an ounce of water every sixth hour will be advisable; the chloral hydrate in thirty grain doses did well in my hands, repeated every eighth hour until sleep sets in, these hypnotics are best administered after the patient is somewhat tired after a walk, and settled in bed. When driven to opium, other sedatives failing, I give a draught of thirty minims of laudanum with twenty minims of tincture of digitalis with an ounce of water, this seldom has failed in my hands, and seldom required to be repeated, the complete successful result of either of these means mentioned above will, very much depend on having a steady rational attendant who will silently sit at the bedside, having the room darkened, and securing strict silence through the house, the attendant should soothe, encourage, and disabuse the patient's mind of his imaginary dangers, he should invariably speak to him in whispers, as the patient imitatively is almost sure from that forth to speak only in whispers, an evident advantage removing one of the elements of disturbance, loud talking, and thus tending to favour sleep; in fine, the ideas of calming, soothing, encouraging the unfortunate patient to sleep, and constantly impressing the necessity of sleep on his mind, should be the responsible duty of the attendant more particularly after a sleeping draught has been administered.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the Medical Press.)

No. X.

TREATMENT OF SEWAGE BY SUBSIDENCE AND FILTRATION.

As an example of the effects of *spontaneous precipitation*, the sewage works at Birmingham may be referred to. They are situated at Saltley, about three miles to the east of Birmingham, and they consist of four sets of subsiding tanks in series, with weirs and floating boards to keep back the suspended solid matters. The arrangement of the tanks is as follows:—The sewage, which amounts to about 17,000,000 gallons a day, is discharged from the main sewer, through five openings, into a subsiding tank about ninety feet wide and fifty feet long; it then flows over a weir, guarded by floating boards, into a second tank of the same dimensions, and then it flows over a like weir into a third tank which is 150 feet long and 30 feet wide from which it passes over another weir into the fourth subsiding tank, which is about three times the capacity of the last, and, finally, it flows over a long surrounding weir, which is only half an inch below the level of the sewage water, into a channel which conveys it into the River Rea, at its junction with the River Tame. In this manner a large portion of the suspended matter of the sewage is retained, for it takes about two hours to pass through the whole series of tanks, and during this time a considerable subsidence of the insoluble matters must necessarily occur, but still the effluent water is very offensive, and is a cause of serious nuisance to those who have an interest in the river below the outfall. There are two sets of these tanks at the works, and when one set has been in operation about a fortnight, it is so charged with sedimentary matter as to require cleansing, and then the other set is brought into use. The sedimentary matter, in the form of a black sludge, is removed from the tanks by means of buckets on an endless chain worked by steam power, and it is run into properly prepared pits, where it consolidates by evaporation and soakage, so that in the course of twelve months it is fit for sale as manure. It then contains about 50 per cent. moisture and 17 per cent. of organic matter, and the farmers take it at the price of one pound sterling for a barge-load of from 25 to 30 tons. The whole of the works are in a very unsatisfactory condition, and are a serious nuisance to the neighbourhood.

The *combined system of sedimentation and filtration* is scarcely more successful. At Coventry, where it has been for a long time in use, the sewage from a population of 43,000 persons, is received into a tank about 150 feet long and 49 feet wide, and 9 feet deep. From this it passes through a lateral filter of coarse gravel running the whole length of the tank, and is received into a second tank of the same dimensions. From this it passes through a similar lateral filter of finer gravel into a third tank, and thence it passes over a weir into the tail brook. There are two sets of these tanks, and each works about a month, when the sedimentary sludge is taken out and mixed with the ashes and sweepings of the town, and sold for manure at the rate of 2s. per load of a cubic yard. The works were

nearly self-supporting, but the purification of the sewage was very imperfect, and hence it is to be abandoned.

At St. Thomas, which adjoins Exeter, the local Board have adopted a similar method of defæcation. The sewage, which amounts to about 200,000 gallons a day, flows to the works, which are about a quarter of a mile from the town, and there it receives a graduated dose of crude carbolic acid (about three-quarters of a gallon of carbolic acid, with a little lime and 250 gallons of water being so used every day). The sewage then flows into two subsiding tanks, and after passing through a coarse strainer of perforated iron, it is filtered through a lateral filter of coarse gravel about two feet thick, which forms the side boundary of the tanks. The effluent sewage is still turbid, but the presence of the carbolic acid completely prevents putrefactive decomposition, so that the effluent sewage passes alongside of the railway in an open channel for about a mile and a half, to the outfall into the tidal part of the River Exe, without causing the least annoyance. The tanks and filters are in duplicate, so that when one requires emptying the other is in use. Each tank works for about six weeks, and then the sedimentary matter is removed and mixed with the town refuse, and sold for manure at the rate of 5s. a ton. About 400 tons are thus obtained from the tanks every year, and as the effluent water is not a cause of offence the operations are successful. The effect of the carbolic acid in preventing the putrefactive decomposition of both the sludge and the effluent water was most remarkable, for even in the hot weather of last summer there was no offensive smell at the works.

At Uxbridge an attempt was made to purify the sewage of 10,000 persons by subsidence and subsequent filtration through charcoal before it was discharged into the River Colne. The sewage, which amounted to about 135,000 gallons a day, flowed to the works by gravitation, and after passing into a subsiding tank about 50 feet long and 15 feet wide and 4·5 feet deep, where the coarser solid matters were deposited, it was strained through a grating, and then filtered through twelve boxes of coarse vegetable charcoal, each four feet long, and two wide, and one deep. There were two sets of these filters, which were worked alternately, and when the filter ceased to act the charcoal, together with the solid matters, was removed and mixed with the town refuse and sold for four shillings per cubic yard. The process was so imperfect that it was abandoned in the year 1857, in consequence of a motion to the Court of Chancery for a breach of the injunction granted in 1855, restraining the Local Board of Health from discharging sewage into the River Colne, "otherwise than in a state deodorised and free from anything offensive." The original sewage, at the time of our examinations in 1857, contained forty-one grains of solid matter per gallon, of which 6·75 were organic; and the filtered sewage contained thirty-six grains per gallon, 5·4 of which were organic. The filters, therefore, removed about five grains of solid matter, of which 1·35 were organic.

Very dilute sewage, with only a small quantity of suspended matter, is still less affected by filtration, unless the filters are well constructed. An example of this came under our notice, in 1866, at the little town of Alton in Hampshire. The population at that time was about 3,800, and the average quantity of sewage was 60,000 gallons a day, the town being very well sewered and drained. On its way to the works, which are on the banks of the River Wey, about 1,000 yards from the town, the sewage received nearly sixteen times its volume of subsoil water, making a total quantity of not less than 1,000,000 gallons of diluted sewage. This was received at the works into two large subsiding tanks, each twenty feet long and seven wide, divided into two compartments by floating planks which kept back the scum. After the separation of the coarser suspended matters, the sewage passed through a series of five filters, composed of coarse shingle, and then it was discharged into the river. The chief constituents of the sewage before and after this treatment were as follows:

Constituents per gallon.	Before Treatment.	After Treatment.
	Grains.	Grains.
Solid matter in solution . .	25·3	24·9
Organic matter . . .	4·8	3·3
Mineral ditto . . .	20·5	21·6
Oxygen required for oxydation	0·300	0·225
Matters in suspension . .	1·7	1·4
Organic matter . . .	1·1	1·0
Mineral ditto . . .	0·6	0·4

The scum was removed daily, and altogether it was found that about ten tons of solid matters were thus separated from the sewage every month.

THE PRESIDENT'S ADDRESS.

THE LIMITATIONS OF SURGICAL ART.*

MR. GAY began his address by an allusion to the war and its lessons; but these had, so far, been but few in number, and those by no means of a novel character, for perhaps the most striking fact, in relation to its appliances, had been reiterated, as the results of war experience since the middle of last century, viz., that in reference to the advantage of "hut or tent hospitals," over the ordinary institutions of that character for its accidents and other eventualites. We are told that in these battle-fields "the miraculous effects of fresh air have, *for the first time*, been fully exemplified in preserving the wounded soldiers from pyæmia, erysipelas, gangrene, and diseases of a like nature, which diseases are still incidental to the casualities of the surgical wards of our Metropolitan Hospitals. Now, in 1755, Dr. Hume observed that a malignant fever which broke out in an American man-of-war, was suddenly and effectually stopped by placing the men so attacked in *old sheltered houses, that admitted air freely*, and in 1764, Dr. Brocklesby, an Army physician, also observed that *sheds covered* over head *that open at the sides*, the exact prototypes of our hut hospitals were the most salubrious hospitals; and the records of more recent wars than of the Peninsula—the Crimean and Austrian—have reiterated and vouched for the same important truth. And yet such is the disinclination of generations, like men to profit by these lessons of a previous century, that apparently this one lesson had to be learnt, if not to be discovered again in our time. Having asserted the proposition

* Abstract of Address, delivered before the Medical Society of London. By J. Gay, Esq., F.R.C.S., President.

that surgical art is behind its privileges, that in other words, it has not attained those limits of therapeutical success to which it might fairly have aspired, Mr. Gay proceeded to discuss the hindrances which have stood in the way of its legitimate advance. Amongst these was, first perhaps, an undue estimate of the strictly mechanical resources of the surgeon. Dexterity and tact in manipulation and the performance of operations are unquestionably of the utmost importance, but they are not *all*-important. They are only successfully employed when they maintain due relation to the exact amount of healing and reparative powers with which the organism happens to be endowed. It is by the admission of this truth, that surgical art gives the lie to that empirical view of it, which makes it essentially "curative;" and it asserts its real nobility when it disdains to appeal to the silliness of mankind by arrogating to itself any such pretensions. A *cure* is a *miracle*, and, in the advancement of our science, we are taught more and more the encouraging truth of inspiration that "*healing* comes from above." The power of the surgeon's art is liable to be defeated by other, and a somewhat large and imposing array of hostile forces. Of these, some appertain to the injury inflicted whether accidental or designed; others to the individual; a third set to the states of the system as affected by organic lesions, such as albuminuria, diabetes; whilst a fourth embraces those disorders, chiefly of zymotic origin, which succeed to the injury, as erysipelas, pyæmia, gangrene, &c. Of these, some are fixed and inevitable, such as age, sex, and temperament, the nature of the injury, and the contingencies of the second and some of the third class; others are also fixed and determinate, but the obvious results of agencies that are preventible or depraved states of constitution; whilst those of the zymotic class may be said to be foreign to the injury, and induced by causes that are also in a very great degree, beneath control. It is to some of the preventible or controliable enemies of surgical art that the following remarks are intended to apply. A wound made in an operation, comes to a certain extent under this category. What makes one wound more hazardous than another? Certainly not size, nor, abstractly, proximity to the trunk, although as a matter of fact, wounds characterized by the latter peculiarity are more formidable than wounds remote from it. At the same time, some small wounds on the trunk, are infinitely more hazardous than large ones, and some large ones are less hazardous in the limbs than smaller ones. On taking wounds generally, comprising those that are accidental as well as designed, it would appear that the source of their relative danger or peril, lies *in their proximity to, or more especially as they involve parts or organs that are supplied by the sympathetic system of nerves*, or the nerves of organic life, wounds of organs, and more especially still, wounds involving the *large* vessels of the trunk are much more hazardous than other wound. The brain-tissue may be wounded with comparative impunity, especially in its upper regions; but wounds of the dura mater and along the tract of its large vessels, independently of hæmorrhage, are very serious, and it is to diseases along these tracts, with which some of the most severe and insidious diseases, such as convulsions and diabetes are found to be closely associated. Dr. Crisp, from his laborious statistical enquiries, tells us that the ligature of large arteries, although unattended with large wounds, are preeminently fatal, and that from pyæmia, erysipelas, &c., &c. The peril attending the opening of serous sacs, appear to be derived from their continued potency rather than to the wound. If it be immediately sealed up, as in the operation for the removal of a loose cartilage from the knee-joint, no harm whatever usually ensues. Exposed to the air, the serous membrane becomes pyogenetic and itself degenerates, a change sometimes utilized. The same result does not follow the prolonged opening of mucous cavities, such as of the stomach and bladder, showing that the change in the former is due to causes inherent and peculiar to the organisation of the membranous tissue, and not to foreign agency conveyed through the admission of the atmosphere. The mode of making a wound too seriously compromises the issues, locally as well as systematically. A clean cut is less perilous to the system, and less difficult of repair, than a laceration. The different extensibility and retractibility of the various tissues implicated, constitute the source of its hazard. The surfaces defy exact coaptation, the essential condition of primary or adhesive union; whilst the exposure of nerve-fibres through the greater retractibility of muscular, elastic, and other textures, and often the irritation of foreign bodies, causing the laceration, such as an impacted splinter of wood, are sources of considerable and independent danger. A wound should be made by the sharpest knife and the finest saw, and by a few deliberate rather than by a number of higgling and heedless cuts. No part of a wound, in a surgical operation, should be made by tearing. In lithotomy, the principal cause of its present state of mortality arises from tearing the prostate and neck of the bladder. The healing of a clean made wound by first intention is, in Mr. Gay's experience, furthered by sealing them up, for which purpose the external application of a compound of tannin, zylidine (made by the action of nitric acid on starch), and ether. Dr. Richardson's "styptic colloid" is exceedingly well adapted. Fresh lacerated wounds should be adjusted whilst the blood is oozing from their surfaces. The irregularities are thus filled up by organizable material, and the wound, in some respects, reduced to the physical condition of one that has been evenly cut, whilst the exposed nerve and other fibrils are thereby protected as by the finest wool, and kept alive by the best elaborated nourishment. The écraseur should, for these reasons, be condemned. Its power of restraining hæmorrhage is questionable in the highest degree. Mr. Gay, in his experience, does not remember an instance of *dangerous* hæmorrhage from a deep, but healthy wound, otherwise than from a vessel which, according to the canon of surgery, it would be unsafe to wound, unless its trunk had been previously secured, —a vessel for which the écraseur would not of itself prove an insufficient deterrent. In order to secure large vessels, the ligature must maintain its pre-eminence over acupressure and torsion. It has yet to be shown that the risks of secondary hæmorrhage are greater after the silken ligature than after the other methods referred to; or that it specially interferes with the immediate action of a wound. Mr. Gay has been in the habit of using small silk ligatures, and of cutting them off short, and he has not had reason to be dissatisfied with the results. The antiseptic animal ligature of Mr. Lister seems to be a very valuable material for delegation. As to secondary hæmorrhage after the use of ligatures made of silk it is exceedingly doubtful, to say the least of it, that it is due to the material itself. As far as the records of cases inform us, secondary hæmorrhage arises rather from some degeneration of the coats of the vessel and follows acupressure and torsion as well as ligature. Pyæmia has been known to follow the one, as either of the other modes of securing the vessel. Tension on the side of an excavated wound, for the ostensible purpose of reducing them as nearly as possible to the condition of a simple incised wound is unfavourable to their healing, as it really creates that objectionable kind of wound in which there is depth and breadth at the base, with a narrow outlet—a wound which in surgery, when immediate action is not intended, as, for instance, in opening the knee-joint, in lithotomy, or hernia, should be avoided. Mr. Gay then treated of pyogenesis in reference to wounds, with the view of showing that in healthy open wounds it was a normal process; and strikingly in contrast with that by which pus is formed in chronic abscesses or disorders associated with depraved constitutions. In both, pyogenesis results from a waste of blastematous products: in the former by the differentiation of blastema (whatever that may be) from its ordinary resultant tissue cells, into normal pus cells; in the latter by the like process of differentiation, but into unhealthy products, akin to normal pus cells, but *only akin* to them. There appears to be some truth in the observations that have been made with regard to the development of putrefactive processes on new surfaces by the instrumentality of organ germ cells—a subject that is exciting considerable attention on all sides. And the subject is of the highest consequence to the surgeon, as it affects questions which are at the foundation of some of the most important issues of his art. Such germs have been found in abundance in the immediate vicinity of a patient with hospital gangrene, and collected from the dust of a ward so inhabited. Now, hospital gangrene has been shown to be an essentially contagious disease. Separate other patients from one from whom these germ cells are obviously being eliminated and the disease ceases to spread. Moreover, Mr. Lister informs us that by the antiseptic destruction of these germ cells, or, at all events, by using antiseptic measures in the dressing of wounds, the mortality after wounds and operation in the Royal Infirmary in Glasgow has been very greatly reduced. The inference from this syllogism is very strongly in favour of the position sought to be established—viz., that many of the diseases which follow the infliction of wounds is due to the

results of germ-producing putrefactive processes in their exposed surfaces. The influences of season, temperature, barometrical pressure, the electrical condition of the air, moisture, and even of the force and direction of the wind, next came under review; and reference was made to a very able memoir on this subject by Dr. Richardson, in which the rules of favourable and adverse interference were clearly laid down. Mr. Gay then passed to the consideration of those acquired states of the constitution which affect the tolerance of wounds and other injuries; and referred at length to the influence of long exposure to vitiated air, of unwholesome and inadequate food, depraved habits, depressing passions and emotions, particularizing more especially the habits of the drunkard and debauchee. No skill could prevail against a "nutmeg" liver, or a "tuberculated" kidney. The effects of alcoholic stimulants has been shown by some experiments by Parkes and Wallowicz (reported in the *Transactions* of the Royal Society), and also by Dr. Richardson, to fall most seriously and directly on the heart and the large blood vessels. Taken continuously they lead to disease of the coats of these vessels, and to intermittent action. The habit of taking stimulants with the persuasion that in health they *save*, and in disease *cure*, is becoming, *under the sanction of the Profession*, a serious evil; since it is gradually spreading, almost as a fashion, through the middle and higher classes of society. The champagne, the port wine, and the brandy bottles are beginning to be as much an habitual resort under temporary ennui or languor, whether from indolence, dissipation, or indisposition, as the gin flask to depraved poverty under the maddening burdens of remorse and despair. The same false views of the value of alcoholic stimulants, and as well as strong nitrogenous beverages, has led to another mischievous practice—one that is eminently unfavourable to surgical art—viz., that of urging a patient, labouring under long chronic disease, and especially in prospect of a severe operation, to swallow as much brandy and beef-tea as he can be got to take in. The condition resulting from this practice, indicated by a black, dry tongue, a brick-dust, sallow face, a feeble, oft intermittent pulse, and an incessant drain on the bowels, vainly attempted to be checked by quarts of chalk mixture is of all conditions most unfavourable to surgical success. It is the exact reverse of this state—viz., the absence of all excitement and casual disorder to the system that leaves the resources of nature most free to act beneficently in times of her greatest need; and that should, if possible, be secured on all such occasions. The subjects of pyæmia, hospital gangrene, erysipelas, and other diseases, principally of the zymotic class, contingent upon wounds, next came severally under review; and the advantages of fresh air and healthy exposed situations were insisted upon as being most likely to exempt the surgeon from the too frequent failures of his art, consequent upon the supervention of these diseases. War, and the management of troops, have proved indisputably that men can endure fatigue and the extremes of climate better without than with the use of alcoholic stimulants; and they have also reiterated the lesson as to the paramount benefits of fresh air. These several diseases are not, perhaps, so formidable from the *number* of the cases in which they respectively present themselves in the Metropolitan Hospitals, as from their relative *high rate of mortality*. Although there has been an interesting contest between the late Sir James Simpson and Messrs. Holmes and Callender on the subject of our present hospital system—Sir James insisting that it is not calculated from the need which it enforces of overcrowding, &c., to ensure that amount of freedom from them which is met with in the small rural hospitals, yet there can be no doubt that the important facts elicited in the course of the contest, and admitted on both sides, lead precisely to the same results. The facts contributed show incontestably that in *large hospitals*, in crowded cities, pyæmia is very apt to arise after surgical operations; whilst gangrene and erysipelas are most frequently imported into them from the "fever-dens" of ill-regulated houses and filthy neighbourhoods; that, in short, overcrowding and the absence of an abundant supply of wholesome air, are the sources of those malign diseases which are so adverse to the success of surgical art. It is time that our large hospitals should, in imitation of the example of Greece two thousand years ago, as recorded by Plutarch, and in accordance with the lessons taught by our modern battlefields, and by still more modern science, bestow a portion of their large resources in order to provide establishments, or, as they were called in ancient times, "Temples of Health," for those exceptional cases which are known to be most unfavourably affected by impure air and crowding, in high situations where the air is wholesome. The heights around London are all that can be desired for such establishments, both in respect to air and convenience of transit. To neglect these lessons on the part of our hospital authorities is to be obtuse to all the inculcations of experience and true wisdom. Modern nursing is an immense advance upon the old system, and the air of cheerfulness and the inspiration of hope —"hope that, not surfeited to death, stands in bold care"— that usually pervade the wards now in consequence of it, go far in sustaining patients, and carrying them successfully through severe trials. It was a noble act and example that of one of our Princesses, in giving pictures wherewith to enliven the wards of a Royal Hospital. After commenting upon other related topics, Mr. Gay concluded his address thus:— "I have in this avowedly simple and discursive address said nothing new. I have merely brought under your notice some old facts and experiences; the more valuable, perhaps, because, like old wine, they have stood the test of time, and have been refined by it too. I have repeated them, not only because I am desirous that the principles which they represent should be utilized by us on every available opportunity, and with all our power, but that we should start on the pathway of new and further research from the platform which they have erected. I have repeated them, because I feel assured they help us to the solution of difficulties which beset the surgeon in his endeavours to attain for his labours that full measure of reward to which he is entitled to look; and, finally, because I would awaken that earnest jealousy for the repute of our art which will brook no rest, no content, until it ceases to suffer from the stigma of unattained, but attainable, success."

DIALECTICAL SOCIETY OF LONDON.—Oct. 5.

At a meeting of the above society, Dr. C. R. Drysdale in the chair, a paper was read by Thompson Dickson, Esq., M.D., M.A. Cantab., on "Baby-farming." After the reading of this paper, which will be found in our last issue,

Dr. Edmunds gave an interesting account of the result of a prolonged interview which he had just had with the woman Waters, at that time under sentence of death. According to the statement made by that woman, she had never actually intended to take away the life of any child confided to her care; but, for the most part, she received the children and gave them away again to other advertising women at a smaller sum than she received. In some instances she placed infants in the arms of boys or children in the street and then absconded, when the children were taken off to the workhouse by the policeman. When a child died she often wrapped it up in paper to save the expense of burial, and put it in some out-of-the-way place. Dr. Edmunds thought that it would be a great mistake if the sentence of the law was carried out in this case, as he was convinced that the woman was not guilty of murder.

Mr. Levy thought that the people of England were now imitating those ancient people, who were in the habit of first gorging themselves with food and then taking purges and emetics to get rid of the surfeit. We made a number of bad laws and then punished those persons who infringed laws which should not have been made. The great safeguard of infant life, he maintained, resided, not in laws, but in sentiment. The infant is so dependant that it was not necessary that anything more than neglect should take place for it to die. Parental affection is the great guard of infant life, especially, too, maternal affection. And how does society act, he asked, in cases of maiden mothers? Does it stimulate maternal affection, so as to protect the child? By no means. The mother finds all doors barred against her, and is soon not only disgraced, but starved. The father is received into society, and has only to pay about 4½d. a day. Illegitimacy laws are foolish. There is nothing in nature to indicate illegitimacy. The bastardy law ought to be abolished. Mr. Levy said that he heard in a neighbourhood in the East-end, where plenty of legitimate children were wished dead by their parents. It was not likely, too, that women could care much for their infants when their husbands were hateful to them, and thus the present marriage laws were a great cause of infanticide. Again, if people only had children when they desired to have them, there would be far less infanticide. Servant girls, for instance, only got children because they knew no better. He doubted much whether the registration suggested by Dr. Dickson would do any good.

Mr. Wilson was of opinion that the State interfered already too much in the care of children by their parents, and

thought that until an infant was of one year of age it should be looked on as the property of its parents.

Mr. GEARY said that the grounds on which we prohibited child-murder were those of utility to the State. The State wanted to have plenty of persons for the business of defence and for labour. With regard to Mr. Levy's views, he urged that if it were acknowledged to be good to prevent the birth of children, it would logically follow that the fatal effects of baby-farming were not to be deprecated. The theory of Mr. Levy and Mr. Wilson was, in fact, against the notion of preservation of infant life.

Mr. LEVY remarked that the sanctity of human life forbade infanticide, whilst it by no means forbade the having of only that number of children which could be comfortably brought up by the parents.

Mr. REED thought that the views of Mr. Levy were the most humane, and that the indiscriminate way in which children were procreated in this country, only to suffer and die, was disgraceful to civilisation. Mr. Levy's views were at the root of the whole question; but he thought that some supervision of nursing establishments would do good.

Mrs. BOON thought it a hard case that children were looked on as a luxury in one class and a disgrace and a sorrow in another. There did not exist a greater prudential Malthusian in England than herself (for Mr. Malthus' own remedies were impracticable). It was a sin and shame that some women were not allowed to have children all their life, because of their circumstances. Every woman should be allowed to be a wife and mother. Medical men often told rich married women without children that a baby would do their health good. Was this only true for rich women? She was greatly distressed to see so many feeding-bottles in the shop-windows now-a-days. And thought that people should not ill-treat maiden mothers, as they do now, if they wanted to get rid of baby-farming or infanticide. Baby-farms ought to be inspected.

Dr. RUSSELL ROBERTS said there were two points for consideration—(1), what were the remedial measures that could be used at once? and (2), what was the radical cure of the disease? The phenomenon of over-population was of course at the root of the matter; but they might also invent some measure which should tend towards diminishing the evil, by acting on the will of the public.

Dr. CHAPMAN said the great majority of children in baby-farms in London were, he presumed, illegitimate. He greatly objected to State aid in this question, as in many others. External defence of the country and the administration of justice are the sole legitimate provinces of the State. The more that children can be kept at home the better, and the chief cause of baby-farming resides in a fundamentally wrong feeling with regard to woman's conduct in respect to her partnership with the other sex. If an unmarried woman has any sexual contract out of that prescribed by law it is now looked on as one of the most grievous of evils. The fact was, women were regarded as property; and the sin of the woman was in reality a sin against the man who was some time to become her owner. Until women became more pecuniarily independent, little would be accomplished to do away with baby-farming, &c. He was opposed to Government inspection, as it would only tend to increase baby-farming and child-murder. Discussion was the thing needed.

Mr. GATE agreed with Mr. Geary, and thought that Mr. Wilson's views gave the right to the parents over the life of their infants. He could not even agree with Mr. Levy's prudential views.

Mr. ACTON was greatly interested in the views expressed by Mrs. Boon, which had struck him as so novel and curious, emanating as they did from a lady, that he hoped that Mrs. Boon would not object that they should be published.

Mrs. BOON replied that she was in such a position in life that she was not afraid of the criticism of any person so long as she said what she believed to be true, and she had no objection to her ideas being published.

Mr. ACTON asked whether any of the members of the society were aware what class of women received the benefits of the Foundling Hospital in Great Coram street. He had made inquiries everywhere to no purpose. He heard it suggested that lady's maids' babies were the chief part of the inmates, but it was very difficult to arrive at the truth.

Dr. C. R. DRYSDALE said that, on the evening of the adjournment of this debate, he proposed to give an account of the phenomenon of baby-farming in Paris, where 14,000 infants were annually put out to nurse by the married and unmarried women of that city. Mr. R. Harte will open that debate, which was adjourned until the evening of Wednesday, the 2nd of November, at 8 p.m., at the Society's Rooms, No. 1 Adam street, Adelphi, Strand. Members of the Medical Profession interested in such questions are invited to attend.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

DR. CLARKE, R.N., communicated the following:—Four instances of injury of the spine have been brought under my observation and treatment during the last few months. They all presented features of great interest, and differed so much in their nature as to make each one an instructive example of some of the various accidents to which the spinal column and its contents are exposed. I shall, however, only incidentally allude to three of the number, for my object in claiming your indulgence for a few minutes is to detail the history of the fourth and only fatal case, as I consider it to be one of more than ordinary character. In two of the survivors, the blow or fall produced concussion and possibly some laceration of the cord or subacute inflammation, for in them paraplegia is more or less present, the functions of the bladder and rectum are disordered, and the constitutional disturbance is considerable.

In the third case, a mass of clay fell a height of twelve feet upon the back of the man, and, as he said, doubled him up, and the result was a dislocation of the last three lumbar vertebræ, with marked angular curvature, the most prominent process being that of the fourth vertebra. In this man retention of urine required the use of the catheter for four days, and enemata were required to empty the bowels; there was partial loss of sensation and of motion, with troublesome cramp in the legs. All these symptoms, together with pyrexia, gradually subsided and he is now, after the lapse of five weeks from the date of the accident, capable of progression with the aid of crutches. The case proves the remarkable power of recovery, or I might say of accommodation or readjustment possessed by the cord after injuries and displacements from which it sometimes suffers. It recalls to my memory an example of restoration which much more strikingly than this, points to the necessity for a guarded prognosis in cases of injury to the spine. I refer to a man who was captain of one of the tops in the second commission of the gun brig *Daring*. He fell from the top, and when I saw him, a pensioner in Greenwich Hospital, he was absolutely paraplegic, the distortion of the spine in the lumbar and lower dorsal regions was so great as to preclude, it was supposed, any chance of recovery, and yet that man after being bed-ridden for a long time, subsequently got about on crutches, and finally dispensed with their aid altogether.

To the case, however, for which I invite your particular attention; the man from whom, *post-mortem*, the portions of bone now on the table were removed, was forty-two years of age, and described as a sailor. He was employed on the morning of the 25th of February, in assisting to roof a shed adjoining one of the basins of the Dockyard. From the neglect of some precaution, on his own part, in slackening a rope of which he had charge, he fell from a height of twenty feet. I saw him within a few minutes after his fall; he was then sensible, but confused, and his memory for a few hours continued to be impaired. I found a long scalp wound extending downwards and backwards from the left parietal to the occipital bone, and a fracture with depression of the parietal at its posterior superior angle. The only other mark of injury was a patch of ecchymosis about the size of the hand over the right buttock. A very few hours elapsed before he recovered his consciousness, and although he wandered at times, his intellect generally speaking was unimpaired to the last, so that operative interference with the skull was not indicated, and I presumed that the fracture was either confined to the outer table, or that the depression, if any, was extremely slight. To his back he referred most of his discomfort, and his suffering seemed to be intense, either on the effort to turn him on his side or when he coughed. I had known the man as a frequent applicant for relief from lumbago, and in the absence of paraplegia or of any external sign of injury to the back, I was at first inclined to attribute his lumbar pain to an increase of the old disorder. However a train of symptoms set in that pointed to deep seated and yet obscure injury. Rigors, œdema of feet, meteorism, distressing singultus, dyspnœa, fluttering and bounding pulse, followed each other

in regular order, and death ensued from exhaustion and such symptoms of cardiac oppression as may be observed in hydrops pericardii.

The record of the changes in his condition from day to day is minute and valuable, for as we read of the sudden accession of rigor and incessant hiccough at midnight on the 27th of February, we can trace the origin of suppuration, and then the progress of pus upwards, exciting irritability of the stomach. Singultus and interference with the functions of the diaphragm by pressure on the phrenic nerve, and finally dyspnœa with laborious action of the heart, while the pressure of pus also as it took a downward course impeded the circulation in the vena cava, and gave rise to œdema in the feet. I have already referred to the absence of any external sign of injury to the spine, but we had abundant proof, inferentially, that the lumbar region was the seat of serious mischief; thus on the 7th of March, it was noted, that he felt to use his own words, as if the spine of his back was coming in two.

On the 8th, the spinous processes were all tender on pressure, but chiefly so in the lumbar region. On the 9th, he stated that he had not any power in his loins. I was summoned to him at 8.30 on the night of March 15, and found that his life was in imminent danger; the pupils were much contracted, his pulse was small and fluttering, deglutition difficult, and he died at 10.50 p.m. I have little to say about the *post-mortem* appearances, for the parts that are presented for your inspection, plainly exhibit the formidable lesion of the spinal column, and account for many of the symptoms which were observed during life.

The fracture of the parietal bone was stellated, and extended to the inner table, but the depression was slight and uniform; was in fact a bulging if I may say so. The area of the fracture will be found to occupy the interval between the main branches of the middle meningeal artery. The brain of course was uninjured, there was not any sign of inflammation, and the healing process had been going on satisfactorily. On lifting the sternum from the thorax, the anterior mediastinum was seen to be full of pus, which was in contact with the pericardium. It was then traced under the crura of the diaphragm downwards as far as the crest of the ilium, and among the muscles in the loins.

The exposure of the lumbar vertebra soon laid bare the peculiar and yet conspicuous breach in the body of the second bone. The fracture, which was comminuted on its upper edge, extended from the root of the transverse process on the right side obliquely across the body of the bone, terminated on the left side a little to the left of the median line, and penetrated into the cancellated tissue, but left the spinal cord intact. It was, in fact, what may be termed a green fracture, such as is seen occasionally in the broken bones of children, and must have been produced by a forcible wrench or flexure of the two extremities of the column backwards. The cord was perfectly healthy; the canal smooth and free from any unusual appearance, except on the left side corresponding with the second and third lumbar vertebra, where there were two small patches of ecchymosis between the meninges and the canal, so thin however, as to have exerted but little pressure on the cord, and it is probable that the slight formication in the legs and feet, of which he complained, as well as the peculiar impression produced by the contact of one foot with the other (the feet felt, he said, as if they did not belong to him) may have been the result of the pressure from those minute effusions.

Royal College of Physicians of London.—At an extraordinary meeting of the College on Monday, the 17th ult., the following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted Licences to practice Physic, including therein the practice of Medicine, Surgery and Midwifery.—Arthur Cooper, M.R.C.S., 25 Stamford street, S.E.; Alfred Stanbanks Drew, M.R.C.S., Stow-on-the-Wold.; Laurence John Halket, The Infirmary, Newcastle-on-Tyne.; Arthur Harris, George Rawson, Thames Side, Staines, W.; David Mathias, M.R.C.S., Cardigan.; William Paulson, 11 Falmouth road, S.E.; Henry Edward Symons, M.R.C.S., St. Bartholomew's Hospital, E.C.; Charles Tanfield Vachell, M.R.C.S., King's College Hospital, W.C. The following Candidates having passed in Medicine and Midwifery, will receive the College Licence on their obtaining Qualifications in Surgery recognized by the College:—Francis John Crane Parsons, 5 Heathcote street, Mecklenburgh square, W.C.; Charles Lyon Vasey, 5 Cavendish Place, W.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 2, 1870.

MR. GOSCHEN ON CUBIC SPACE AND UNIFORMITY OF RATING.

Last Session, owing to the squabbles among the Guardians of St. Pancras and the Poor-law Board, an Act, called the "Metropolitan Poor Amendment Act," was passed, and this Act came into operation, it seems, at the beginning of the month of October. It will be doubtless interesting to all medical men to know how far this Act is likely to prove in unison with what are known to be facts in the science of hygiene. The first provision of the Act is intended to prevent the over-crowding of workhouses; and henceforward the cost of the maintenance of indoor paupers in the metropolis is to be paid out of the Common Poor Fund, and the Guardians will be required to draw the monies they pay away from the central treasury, in the shape of repayments, at the rate of 5d. a day for each inmate. The Poor-law Board will now have the whole of the indoor poor of London under their control. Each workhouse and asylum has been surveyed, and the number of inmates which it can fitly receive is accurately known; so that local guardians can never draw for more money than their workhouses will sanction. It seems, however, that there are two dangers yet to be apprehended. Firstly, children under sixteen years of age may be retained in the workhouses, instead of being sent off to the school: and some guardians may huddle together the whole of the inmates allowed to their workhouse in but a few of the wards, instead of distributing them over the whole area of the house. The first of these evils is guarded against by a regulation that, although in case of asylums the guardians may claim for the maintenance of every pauper, they are not entitled to demand repayment for the maintenance of children of school age.

As to the over-crowding of wards, there is a regulation to the effect that, in case of re-distribution of the internal space of a workhouse being necessary, the guardians shall communicate with the Poor-law Board before making it. Allowance is to be made, however, for the difficulties of guardians in building new workhouses; and there is a certain indication that the Board will not be too hard

upon guardians when in difficulties. Perhaps, indeed, it may be urged that the Poor-law Board is too lenient in its commands to the guardians; but, after all, we must all of us "allow for friction," as the student of theoretical mechanics is obliged so often to do.

The principle on which the Board has estimated the capacity of workhouse wards is that embodied in the scale recommended by the "Cubic Space Committee," viz. :—"For the sick, 850 cubic feet; for lying-in women, 1,200 cubic feet; sick cases of an unusually offensive character, 1,200 cubic feet; infirm persons occupying the same room day and night, 700 cubic feet; infirm persons able to leave their dormitories during the day, 500 cubic feet; healthy persons, 300 cubic feet. For the two last classes day room accommodation is required, in addition to the amount of 500 cubic feet and 300 cubic feet allotted to them as sleeping accommodation." One or two observations occur to us with regard to these figures. In the first place, we think the allowance of only 300 cubic feet for healthy persons is rather apt to turn them into sick ones; and so long as they are condemned by want to dwell in the workhouse, to render them liable to have tuberculosis engendered. Why should the limit of 600 cubic feet, the minimum required for soldiers, not be required for paupers? Everyone knows that a soldier's life would soon be greatly deteriorated if he had to sleep in such a small cubic space as 300 cubic feet. On what grounds then, has the "Cubic Space Committee" come to the conclusion that paupers will bear the deprivation of wholesome air better than soldiers? The real fact is, they will bear it less well than soldiers, because they are under-fed and in the very conditions which engender fevers and tuberculosis.

Again, with regard to lying-in women, we cannot help thinking that such cases should not be taken into the workhouse at all, or in very small numbers at any rate. The majority of cases, we presume, where women seek the workhouse to be confined, are those of maiden-mothers; but even then we cannot see why a system of help at the patient's own lodging could not be instituted, instead of taking them into hospital. No amount of cubic space can ever make lying-in wards free from danger. We don't exactly understand the rule about 1,200 cubic feet for patients whose sickness is of an unusually offensive character. We presume such cases will only be found in workhouse infirmaries. If so, there are many such where this cubic space would be far too restricted, and where, as in cases of sloughing phagedæna and erysipelas, there would require to be at least 2,000 cubic feet, with constant renewal of the air, afforded to the patient.

But, with these criticisms, we cannot help expressing our high satisfaction at the new system of charging the maintenance of paupers and the salaries and rations of the officers entrusted to their charge to a common fund for the whole of the metropolis. We predict that this will work admirably in London, and are of opinion that all of our cities should be regulated in the same manner. It has long been a scandal to us all, that wealthy parishes in the West-End have contributed almost nothing to the care of the very poor, by whose labours many of the inhabitants were maintained in affluence. There should also, of course, be one uniform rating for the whole metropolis. This will, we doubt not, tend to arouse the attention of even the most thoughtless of the richer classes of the metropolis to the evils resulting from the sea of pauperism with which this great city is being invaded, and may, perchance, make some of them agree with one of the characters in Mr. Disraeli's "Lothair," where he says that the great problem of this time is, how poverty may be extinguished. These questions are not only very important, they are even quite soluble, if attacked with the firm determination to understand them.

THE APPROACHING ELECTION FOR COUNCILLOR IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

The election to the vacancy created by the resignation of Dr. James Barker is fixed for Thursday, November the 3rd, and the approach of that day is regarded with much interest in Dublin.

In addition to those Fellows of the College who may have merely sent their names to the Registrar, there are four actual candidates in the field who will each go to the poll with hope of success:—Dr. Mapother, Professor of Physiology in the College, and for some years a member of its Council; Dr. Robert Smith, Professor of Surgery in the University of Dublin, and Surgeon to the Richmond Hospital; Dr. Darby, of Bray, Medical Officer to the Rathdown Union Hospital, and President of the Irish Medical Association; and Dr. Kirkpatrick, Surgeon to the North Dublin Union Hospital, are candidates, and we refrain from doing more than simply epitomizing the grounds of their claims for the suffrages of the Fellows.

Dr. Mapother has already given guarantees for his opinions on medical politics and his future conduct by some years' service in the Council, and the position which he occupies as a Professor in the College should be a hostage for his fidelity to its interests in the future. Dr. Smith's name is identified with great learning and much eloquence in the teaching of surgery, and the respect which he has acquired will secure to him an active support from those who have been connected with the University which he represents. Dr. Darby is a thoroughly honest and energetic exponent of the views of the Poor-law medical men of Ireland, in whose service he has been untiring and undismayed under the pressure of many discouragements, Dr. Kirkpatrick is also himself a Poor-law Medical Officer, and has been for many years a surgeon of note in Dublin.

The only advice which we feel justified in giving to the electors is that they shall allow no consideration to cause them to swerve from their allegiance to their College. These are not the times for a halting or half-warm policy. The life of the College depends on the loyalty of its Council, and any Fellow who, by his vote, will strengthen the hands of its assailants, already confident and active as they are, will incur the responsibility of sacrificing it to its powerful besiegers. "The College in its integrity, and nothing but the College." Let that be the motto of its Fellows, and it has, as an institution, nothing to fear from the onset which the approaching Parliamentary Session promises us.

Notes on Current Topics.

About the War and Wounded

We remarked last week on the danger to which the neutral badge was exposed. Col. Lindsay who has returned from his mission and given a long account of what he saw and did, confirms very fully all we have said. On this point he writes:

"To preserve to the red cross flag the respect in which it is now held must be our aim and object; but, as I said before, laxity of rules and scandalous abuse of privileges threaten to bring ruin and destruction upon the institution. As our Government has signed the Convention of Geneva, I consider

it only right to ask them to aid in the proper working of the rules which they have agreed to, and this can best be done by some explanations and agreements between the Governments of the various countries, or their representatives. The explanations or agreements should be somewhat as follows:—A recognized badge and paper, signed and stamped by the authorities, should always be carried both by surgeons and lay agents, and this paper and badge should be demanded before giving employment to surgeons or other people. All those who have been sent out by the London committee have both paper and badge, but I regret to say that neither one nor other is, as a rule, ever asked for, and there is nothing to prevent a swindler from wearing a red cross and walking into a hospital and demanding employment as a surgeon, or undertaking to deliver stores, which he may purloin for his own use. The abuse of the red cross in Paris by men who have no right to it has produced the most indignant remonstrance on the part of the newspapers there. An article which I noticed, headed 'Parasites of the Red Cross, describes these men as continuing to wear the badge on their casquettes notwithstanding the disdain and contempt with which they are regarded by all honest men, and thus saving their precious skins from the fatigue and danger of active service. The newspapers demand a most severe law to deal with these impostors. A real service might be done by our Government by helping to clear away the discreditable excrescences which have grown up rapidly upon a noble institution. The abuses, I am sorry to say, are not confined to the *personnel*, but extended even more largely to the *matériel*. Sham hospitals are arranged, or rather houses not hospitals at all pretend to be so, having neither sick nor wounded, nor any preparation for their reception; they mount the red cross flag, and thus escape all billeting of soldiers and imposts of that character. A board stating the number of sick being cared for and the number of beds prepared for their reception should be placed outside the windows. Indignant remonstrances, I foresee, will be made when the war is over on the working of the Red Cross Society."

Again, the gallant colonel confirms all we have written respecting the condition of the sick, the wounded, and the rank and file of the besieging armies of Germany. Here is a revelation:—

"I believe it to be the established system throughout the German army, but it will astonish English surgeons and English people to learn that with the army now before Paris there is no provision whatever for the extra care and comfort of the sick and wounded. No tents, no hospital diet, no blankets, no hospital suits of clothing, no slippers, no underclothing. The old blood-stained uniforms are worn in the hospitals, and again when discharged from them. The men walk about with naked feet and scanty clothes, their rations are issued as usual, and are made the most of. Everything else is supplied by voluntary contribution: and I state it as a fact, and am prepared to prove it if necessary, that thousands of French and German soldiers have had the necessaries of life given them by English contributors to the National Fund. If the Germans err on one side, I am convinced the English err as much on the other. The number of things demanded by the War Office Ambulance for their proper equipment, the Committee are aware, was quite appalling, and yet they were all laid down in the regulations. An English ambulance for 200 beds must cost four times as much as that of any other nation. The harness is heavy and cumbrous, and the waggons require four horses to draw them there is no box from which a man can drive, but every other horse must be ridden, which is a great inconvenience and waste of strength and power. The best ambulance-waggons which I saw were the Americans, which were adapted for two horses, and were, in my opinion, models of arrangement."

***

The donation of £20,000 to the Germans was easily arranged for. It is doubtful if the Parisians would have got their £20,000 unless Col. Lindsay had refused his offer to the Germans, except on the just condition that he should be permitted to enter Paris and give them an equal sum. This is how he arranged in Paris, and why:—

"From the fact of there being no less than fifteen different societies engaged in giving such aid, and each society having its own separate fund, and distributing it for the benefit of its own sick and wounded soldiers, I found it impossible to lodge the money with any one person, not even with the Minister of War, for had I done so, the money would have gone entirely to the military hospitals, to the exclusion of the much more numerous hospitals prepared for the reception of the wounded and sick of the whole male population of Paris, numbering nearly 500,000 men, now under arms in defence of their town. The plan adopted for the distribution of the 20,000*l.* will be seen set forth in letter from General Le Flo, which I herewith enclose. The committee which was formed for the management and distribution of the fund is as given below:—Count Flavigny, President of the International Society; Doctor Ricord, President of the Société de la Presse Francaise; an Intendant of the Military Hospitals; a doctor of the hospitals of Paris; Count Claremont, Dr. Gordon, Surgeon-Major Wyatt, medical officers sent by the War-Office to report on French system."

***

Having said so much of Col. Lindsay's mission, we now proceed to give an account of the other sums spent by the Committee over which he presides. Here are the figures:—

MONEY DISBURSED.

German wounded in the army round Paris, per the Crown Prince of Prussia	£20,000
French wounded in the hospitals in Paris, per General Trochu	20,000
Remittances to various hospitals and persons, principally in the neighbourhood of the Rhine and throughout the Seat of War in France	31,500
Food	8,750
Medical Stores	5,680
Surgical Instruments	5,300
Clothing and bedding	9,160
Surgeons', dressers', and nurses' wages	2,500
French ambulance, cut off from its natural source of supply by the operations of war, and kept in activity by subsidy from this Society	4,000
Ambulance under charge of Dr. Frank, already provided with large stores from this Society	2,500
Large English army ambulance, now at Versailles, first payment on account	6,000
Cost of maintaining depôts under Major-General Sir Vincent Eyre in France, and Captain Brackenbury on the borders of Belgium, Luxemburg, and Germany	6,000
Credits for various purposes, through Captain Brackenbury, our general agent	10,000
Loan to American ambulance at Pasis	800
Salaries, wages, &c.	1,000
Printing, stationery, telegrams, postage	1,000
Carriage of parcels, freight, &c	800
Advertisements in the *Times* and other papers	6,000

OUTSTANDING DEMANDS AND LIABILITIES.—ESTIMATE.

1. Surgeons, dressers, nurses, and lay agents employed throughout the Seat of War, in number about 250, maintained at a cost of more than £200 per day for 30 days	6,000
2. Army Ambulance for transporting sick and wounded, consisting of 12 waggons, store carts, horses, &c.	15,000
3. Complete Field Hospital attached to above, arranged for 200 patients, with tents, surgical appliances, food, &c. The whole under command of Dr. Guy, Deputy Inspector of Military Hospitals, assisted by 12 Army Surgeons	20,000
4. Cost of maintaining depôts under Major-General Sir Vincent Eyre in France, and Captain Brackenbury on the borders of Belgium, Luxemburg, and Germany	10,000
5. Money and stores in course of distribution from time to time to hospitals and ambulances whose funds are exhausted, and who come to the English Society for aid to enable them to continue their work	10,000
6. General expenses of the whole establishment and final cost of winding up	20,000
7. Cost of stores, chiefly food and clothing, to be sent out in readiness for the sick and wounded in Metz and other places	15,000
8. Balance still available to cover all further contingencies and demands	26,000
Present amount of subscriptions	£262,990

STORES FORWARDED.

There have been distributed throughout the whole Seat of War during the month of September, 1,700 boxes and bales; from the 1st to 22nd of October, 1,531 boxes and bales; total number of boxes and bales despatched during the last seven weeks, 3,231. These stores consist principally of contributed articles:—1, Clothing and bedding of all kinds; 2, provisions; 3, medicals; 4, surgical instruments; 5, brandy, wine, and porter. This department is almost entirely under the management of the ladies's committee, whose arrangements have been admirable, and the efficiency and value of whose services are beyond all praise.

Chilblains and Chapped Hands.

THE returning cold, damp weather brings in its train the seasonable series of complaints, such as chilblains, chapped hands and lips, &c. These appear to be most prevalent just now, amongst those exposed to the inclemency of changeable weather, who possess a fair complexion, delicate skin, and other constitutional predispositons. To those specially liable to these tiresome and painful affections, we recommend as a preventitive wearing kid skin gloves lined with wool, which not only keep out the cold, but absorb any moisture that may be upon the hands; and to rub over the hands before washing a small quantity of glycerine, which should be allowed to dry or become absorbed to a partial extent. When chilblains do manifest themselves, the best remedy not only for preventing them ulcerating, but overcoming the tingling, itching pain and stimulating the circulation of the part to healthy action, is the liniment of belladonna (two drachms), the liniment of aconite (one drachm), carbolic acid (ten drops), to collodion flexile (one ounce), painted with a camel's-hair pencil over their surface. When the chilblains vesicate, ulcerate, or slough, it is better to omit the aconite, and apply the other components of the liniment without it. The collodion flexile forms a coating or protecting film, which excludes the air, whilst the sedative liniments allay the irritation generally of no trivial nature. For chapped hands, we advise the free use of glycerine and good olive oil in the proportion of two parts of the former to four of the latter; after this has been well rubbed into the hands and allowed to remain for a little time, and the hands subsequently washed with Castile soap and tepid water, we recommend the belladonna and collodion flexile to be painted, and the protective film allowed to permanently remain. These complaints not unfrequently invade persons of languid circulation and relaxed habit, who should be put on a generous regimen and treated with ferruginous tonics. Obstinate cases are occasionallly met with which no local application will remedy, until some disordered state of system is removed, or the general condition of the patient's health improved. Chapped lips are also benefited by the stimulating form of application we advocate, but the aconite must not be allowed to get on the lips or a disagreeable tingling results.

The Country Doctor and his Work.

THE country doctor's work is for the most part hidden toil, veiled from the public because performed in the dark, and unappreciated because its exact nature and intricacies are unknown. Some of our correspondents living secluded lives in the central part of a district mapped out for them by an ungenerous Poor-law Board, may well shiver at the approach of winter, which is the commencement of fresh danger to them, whether viewed in the light of contracting disease whilst returning from the bed-side, whereat hour after hour there has been anxious ministration in completing an *accouchment*, from the miasmata arising from ill-drained marshes these leaden mornings, or the direct danger to life through accident in travelling in the dark. Last winter we referred to the death of a respected Sussex surgeon, Mr. Noakes, of Newhaven, who, in going to a midwifery case, accidentally fell into a well and was drowned. Not a winter passes but we are called upon to herald the painful intelligence of some worthy member of our body, some hard working, under-paid surgeon, forfeiting his life in the discharge of his duty—duties unrecognised and unappreciated in the broad daylight—sneered at by the vulgar, and envied by others who believe the doctor waddles for ever in clover; because they know nothing of the gullies, the wells, the ill-protected quarry, the headway at night against rain, and sleet, and wind, whose breath and vision are taken away whilst on the dangerous mission of ill-requited mercy, for all, the majority of our brethren, cannot ride in carriages. Down hill, over dale, through treacherous gaps to the house of suffering, and home again to find, perhaps, a journey equivalent in danger and distance to be undertaken in another direction forthwith, and all this exposure to the inclemency of the night, and risk to life, for a few shillings, paid as a rule grudgingly and murmuringly. There should be no better friend to the public than the man who, at all times, in all seasons, is ready to risk his own life in trying to save theirs, and for which no money, so to speak, should be as an equivalent. The members of no other profession will incur the same dangers, or expose themselves to the same casualties. The doctor wants but the word and the nature of his calling not only prompts, but necessitates immediate action. He wanders over heavy roads, through newly-ploughed fields, and upon his patient's case brings to bear his experience and professional abilities. He must never in his own person evince discomfort, or complain in the house of a patient, whilst shivering with cold, or suffering from the effects of exposure, broken rest and irregular meals; he must dissemble, cloak his own troubles, and assume perfect health and power in order to inspire confidence and rally his patients, for none need a broken-spirited, down-hearted, pain-enduring physician to come near unto them in the hour of travail and pain. These remarks are forced upon us because of the complaints which reach us time after time from our brethren scattered through the provinces, and because, we know, before the winter passes, and summer again cometh, that many of those who read our words will have nobly fallen where duty points, in the harness of some ungenerous service such as the Poor-law, or in the ranks of some equally miserly clique. We read thrilling tales of the soldier dying in battle, of warriors who expose their lives in their country's service, being rewarded by promotions and distinctions, but for him who hazards his life in the fever-stricken hovel, and who exposes himself not alone to contagion, but to the infliction of injuries in removing a malignant growth, as in the case of Maurice Collis, there are no rewards, no distinctions—not even the acknowledgment, so encouraging for work well done, for courage brave as any soldiers, and for risks to limb and life which country doctors alone have taught them in their bleak, solitary marches at night, whilst others sleep peacefully in their beds; and for this nightwork there is

no additional rest by day as in other trades involving loss of sleep. The doctor must be at his post, and go through the routine of his work with the calm resignation and placid countenance of an angel. Men certainly know something of all this before commencing the profession of medicine, but what they do not calculate on until they experience it, is the cold indifference of the public, the ill-requited return from patients, who should be generous and thankful, the miserly treatment by beggarly boards of guardians, and the underhand dealings of the clergy who tamper with disease, and invade the doctor's work so thoughtlessly and unbecoming, not unfrequently so disastrously.

Tramps.

The pest of country towns appears to be the tramp—a nuisance to the people whose alms he solicits, and when refused upon whom he heaps a hoard of abuse, which only the professional tramp commands; a worry to the relieving officer whose house he besieges late in the evening that he may obtain an order for a night's lodging and some provisions, for the tramp steers clear of a certain class of well regulated workhouses where they are required to do in return for the meal and lodging a certain amount of work, and a bother to the parish doctor. When the weather is severe, and travelling irksome, the tramp feigns illness and pests the doctor. If a man complains of a certain pain, it is difficult to say he does not suffer from it, but the question should at once arise, is the diseased tramp removeable to the house or hospital? We knew a clean, well regulated village once infected with a malignant and infectious fever, introduced through a female tramp, and propagated by those who, through humanity, waited upon her, whereby out of a population of one hundred and fifty people, before the progress of the fever was arrested and its virulence stayed, twenty-five deaths occurred. The parish doctor was blamed, and disagreeable accusations preferred against him, which was as uncharitable as they were ridiculous; but that in his humanity trying to keep the tramp and carry her through the fever, he was imprudent, there could be no question of doubt. We advise all diseased tramps to be sent at once to the nearest union or hospital, if fit to bear the fatigue of removal, and that the aroused morbid sensibility of a few local philanthropists' opinion should not be permitted to sway the doctor's advice in this important essential. We have known tramps carry infectious diseases from town to town, and from affected to previously disaffected districts, and thus we are only too well aware that their dirty rags propagate and foster more epidemic disease than is generally believed. Scarlatina is carried by these from town to town, as is only too often experienced by our provincial brethren, and the question arises how are these tramps to be regulated and prevented doing, not unfrequently, dire mischief. We believe a system of registration would effect this, whereby the police and relieving officer would have additional duties to perform. Let a permit or pass be given with each tramp from the place where he last obtained relief, and that it be incumbent for him to produce it when needed. We are particular that cattle disease should not spread, and that no traffic should be carried on through infected localities—surely we should be also particular over the still more important subject of the spread of disease through human agency.

Hepatic Rheumatism.

We are favoured by a correspondent with a long letter on the subject of hepatic rheumatism. He illustrates what he is pleased to call hepatic rheumatism—rheumatism supervening upon some disease of the liver, as cirrhosis, abscess, or simple congestion of this viscus—with the particulars of several cases. One especially, his own man servant, a pensioner, who had been resident in India several years, was invalided home, and suffered from repeated attacks of liver complaint, each seizure being followed by well-marked arthritic complications. The same patient had abscess of the liver successfully treated after the method recommended by Waring-Curran, described by that gentleman in a paper published in these pages, and extensively reprinted into the foreign journals from us. Several medical men have been shown this particular patient during the stage of liver derangement, and afterwards when suffering from the hepatic rheumatism, depending on a vitiated condition of blood. The only medicine, we are told, of the least service in the rheumatic stage was the iodide of ammonium, and its properties in checking and eventually overcoming the rheumatism were readily appreciable. The other patients who suffered also from hepatic lesions, followed in due course by rheumatism, either of the joints or muscles, were also treated with the same drug—iodide of ammonium—with the same satisfactory result. We are reminded the iodide of ammonium was first employed, and its virtues extolled in rheumatism, as in the eruptive stages of syphilis, by Dr. Waring-Curran—a medicine which that gentleman considers of greater therapeutic power and importance than the iodide of potassium, in the treatment of diseases which have their seat essentially in the blood vessels.

Army Medical Department.

Staff Surg. M'Nab, M.D., has been ordered from Dublin to York, to take over the duties of the recruiting district from Staff Surg.-Major Fowler. Staff Assist-Surg. A. S. Walker arrived at Portsmouth from Gibraltar in medical charge of invalids in the steam-ship London on the 16th ult. Staff Assist-Surg. West is under orders for India. Staff Assist-Surg. Blake has arrived in Dublin for duty at the General Hospital. Staff Assist-Surg. Haines has arrived at Athlone for duty. Staff Assist-Surg. Ferguson and Mrs. Ferguson will embark in the s.s. *Tagus* at Gravesend on Thursday next for conveyance to India. There will be an examination in January next for three Assistant-Surgeons who may be desirous of qualifying for promotion.

Myelitis.

Dr. Oxley, of Liverpool, mentions a case of Idiopathic Myelitis, in which the patient, a boy of eleven, had pains commencing in the small of the back round to the umbilicus. The pains were worse at night. Micturition frequent, walking gave great pain; pulse 120; bowels, costive; skin red over lower dorsal vertebra. Priapism, and incontinence of urine was followed by paraplegia and anæsthesia extending to seventh intercostal space. Bedsores over sacrum and trochanters. On *post-mortem* examination, inflammatory lymph, extending over lower portion of spinal cord was found. Nothing abnormal was observed, on laying open membranes, but a longitudinal incision of the

cord showed white softening for half an inch, opposite fifth dorsal vertebra, and on section, whitish fluid exuded. The bladder firmly contracted, had an abscess at its upper part. Ureters much dilated, and pelvis of kidney enlarged and ulcerated. This is a very interesting case.

Treatment of Aneurism of the Femoral Artery.

Mr. Russell, of Newcastle-on-Tyne Infirmary, desires to keep before the profession, the treatment of aneurism of the femoral artery by means of rapid pressure; and to this effect, mentions the case of a man, aged thirty-eight, with pulsating tumour of the left groin. After two days' rest in bed, digital compression was made by the hospital staff, in turns of twenty minutes each, for twenty-four hours, commencing at 2.40 p.m. The temperature of the affected limb fell from 90 deg., to 84 deg. On patient complaining of great pain, two grains of opium and two and a half of morphia were administered: and the pupils became contracted. Pressure was made over external iliac. This plan failed. He was then put under chloroform and a horse-shoe tourniquet applied over left common iliac artery at 10.45 a.m. Chloroform was kept up all day and at 7.55 the tumour had ceased to pulsate. He took thirty-five drachms of chloroform. The plan of treatment was successful, and is far less dangerous than tying the artery in such a case, according to Mr. Russell.

Obstetrical Society.

At a meeting of the Obstetrical Society of London, on October 5th, Dr. Grailly Hewitt in the chair, Dr. Protheroe Smith exhibited a specimen of Carcinoma uteri, in which the disease was limited to the fundus. The cervix was not implicated and the uterus was movable. Dr. Martin, of Melbourne, read a case of "Hard Fibrous Tumour of the Ovary, removed by Ovariotomy," which recovered. Mr. S. Wells and others, thought that this tumour was in reality a fibrous tumour of the uterus. Dr. Copeman, of Norwich, mentioned a case of pelvic tumour impeding delivery. Dr. Barnes said that if such tumours contained fluid, it should be drawn off: but this was sometimes impossible. In the latter case, Cæsarian section might be required. Mr. Lowe (Burton on Trent), read a paper on "Hæmorrhage from retained Placenta, after Abortion." The patient retained the placenta for some weeks, and died of pyæmia. The secundines should therefore be removed in all cases of abortion. Dr. Hewitt thought that the membranes, &c., should always be removed as soon as possible.

Clinical Society.

At the first meeting of the Clinical Society, on Friday October 14th, Mr. Spencer Watson brought forward four cases of Parenchymatous Keratitis in young persons under the age of nineteen. He thought medicines which did good to rheumatism, might be useful in such cases. Mr. Croft said that a case like this had got well under iodide of potassium. Dr. John Harley mentioned a case of injury to the liver, resulting from Abscess, in an old man, aged sixty-nine. There was interrupted discharge of pus by the rectum up to the 112th day. There was a tumour in the epigastrium, which occasionally disappeared, this being followed by hectic and jaundice. Dr. Ogle related a case of tetanus in a boy, whose thumb was bruised, and three days afterwards he had stiff neck and gradually all the symptoms of tetanus. He was put fully under the influence of belladonna and chloral at night. The patient recovered. He suspected that, in all cases of tetanus, the temperature increased in the evening. Dr. Chunder Roy mentioned that in India some cases recovered without any medicine, and there were some in which it was of no use.

Heifer and Human Vaccination.

The Medical Department of the Privy Council evinced a very praiseworthy alertness in dealing with the question of animal vaccination, and by a careful investigation conducted in the localities where experience on the subject may most readily be sought for, has weighed and found wanting the process of inoculation direct from the heifer.

In last October Dr. Leaton was directed to visit various parts of the Continent with a view of ascertaining how far cowpox might be transferred from animal to animal without difficulty, the character and course of the disease produced in the human subject by inoculation with animal lymph, the degree of success attending the inoculation, and the extent into which the attempt to preserve the lymph taken from heifers in an active state sufficiently long for purposes of vaccination has been successful.

The results of this enquiry are contained in the last report, and they prove very conclusively that, assuming that there are great advantages in the transfer of vaccinia direct from the cow, yet the difficulties of effecting the inoculation are so great as to make the process all but impossible on the large scale.

The drawbacks to the use of heifer lymph are recapitulated in the Privy Council Report as follows:—

First, that apparently even able and painstaking operators may find it impossible to transmit successive vaccination from calf to calf without very frequent recurrence of failures and interruptions; secondly, that the transference of infection from the calf to the human subject even under the most favourable circumstances (*i.e.*, by experienced operators and with lancet direct from calf to arm) has in it such risks of failure, that, for instance, at Rotterdam, the proportion of unsuccess was nearly twenty times as great as in the ordinary arm-to-arm vaccinations; and, thirdly, that the calf lymph; as compared with ordinary lymph, is peculiarly apt to spoil with keeping, and in the form of tube-preserved lymph can so little be relied on, that the Rotterdam establishment in distributing supplies of lymph now uses only lymph from the human subject. Evidently, then, in the present state of knowledge, a system of animal vaccination would have in it an extreme uncertainty of operation; and this uncertainty would, for obvious reasons, be so conclusive against our preferring the system on its own merits for purposes of public vaccination, that practically we have only to consider whether our own system has demerits entitling it to any considerable mistrust.

It has never been established that arm-to-arm vaccination is objectionable, and the alleged transmission of syphilis and other diseases by it is, as yet, quite unproved. It is not even shown that the specific virus of one contagion is *capable* of containing the spore of another, and until the preliminary step of showing that there is really some danger to be avoided is achieved, it would be ridiculous to incur the certainty of unsuccess in many cases in the hope of thereby avoiding an imaginary shortcoming of the existing system of vaccination.

The Liverpool Epidemic.

The condition of the health of Liverpool to which we have alluded from week to week is becoming very alarming, the severe epidemic of relapsing fever being now supplemented by frequent cases of scarlatina and small-pox hourly increasing in number. Last week there was no room in the workhouse hospital for a single case, and it was found necessary to put twenty-four patients suffering from scarlatina and small-pox in an old timber-shed, and, when it was full, to refuse applicants altogether.

The Medical staff are labouring night and day, having 1,500 cases in hospital, and 314 in their own homes to look after, besides private patients. One of them, Dr. Clements, has already given way and is in the General Hospital. The dilemma is really a serious one, for the Guardians have really done their duty to the utmost in providing accommodation, and yet there is a prospect of their being altogether overwhelmed in their efforts by the flood of cases pouring in on them.

American Medicine.

We publish to-day a most important letter from our special Canadian correspondent on the Act just passed in that colony for the control of the profession. Next week we purpose to report a lecture on "American Medicine," delivered last Monday in Dublin by Professor Mapother, who has recently travelled through that country. In it he contrasted many of the licensing bodies with those of the United Kingdom, and decided in favour of the latter. The amalgamation of licensing bodies and the suppression of quackery, subjects which, as far as regards home, he had fully discussed in his "Carmichael Essay," were the other topics of Dr. Mapother's address.

Prussian Military Punishments.

The mistaken persons in our own country who cannot distinguish philanthropy from maudlin sympathy with culprits who are submitted to the punishments set down by the law will, perhaps, think better of the mild discipline to which English prisoners are subjected, when they compare their treatment with that to which soldiers are submitted in the Prussian army. It appears that, in time of peace, severe arrest consists of confinement in black darkness, with the ground for a bed. Bread and water is the fare in each case. It cannot be ordered for more than five weeks, it being reckoned that longer confinement of the kind is calculated to undermine the constitution. Severe arrest is impracticable in war time in the enemy's country. For it is substituted the punishment of "tying to a tree." Two hours on the tree is reckoned equivalent to twenty-four hours' severe arrest, and the maximum of this punishment is also four days. The punishment undoubtedly is severe. The prisoner is tied round the tree by the arms, by the waist, and by the feet, so as to be unable to touch the ground as a support; and his face is turned to the tree that he might see nothing.

The *Lancet* criticises the disposition to refer everything to "debility." This hobby has certainly been ridden rather hard by the new school and there is danger of the reaction being too violent.

There is a talk of a "Hospital Sunday" for the parish of Marylebone.

The Brighton Guardians have granted a superannuation allowance to Mr. Richardson.

Miss Garrett, M.D., is a candidate for a place on the London School Board.

Miss Emily Bovill has obtained Lady Amberley's scholarship at Edinburgh.

The staff of the Birmingham General Hospital is about to be enlarged.

Yellow Fever continues at New York. Some of the cases have been of a very malignant type.

The salary of their Medical Officer of Health has been reduced by the Birkenhead Commissioners some £200 a-year. Is not this a step in the wrong direction?

Scarlet Fever still increases in London. More than half of the deaths in this epidemic are those of children under five years old.

At Leeds twenty-eight new students have entered. The same number at Liverpool. The other schools have the following entries: Manchester, 36; Sheffield, 7; Bristol, 9; Birmingham, 18; Newcastle, 23.

Dr. Thorpe, of Todmorden, recommends, in cases of obstinate constipation, the throwing up of a pint of warm water into the rectum, by O'Beirne's long tube passed up about sixteen inches into the bowel.

The Royal Society of Medicine seems never likely to be constituted. It has again been referred back to the Committee, and that at a stage when it was thought only formalities remained to be gone through. Verily, we English are slow to change even a name.

SCOTLAND.

Dr. Thomas Anderson, Director of the Royal Botanic Gardens, Calcutta, died at Edinburgh, on Wednesday last. Dr. Anderson, whose failing health necessitated his return to Scotland some months ago, was a most distinguished student and graduate of Edinburgh University.

University of Edinburgh.—The half-yearly meeting of General Council was held on Friday, when the following subjects, specially interesting to the profession, were disposed of:—

Medical Education of Women.—The Vice-chancellor stated that an address from 160 students of medicine had been forwarded to him. (The address conveyed thanks to the members of Council who had opposed the admission of female students into the medical classes.)

Professor Crum Brown moved, and Professor Tait seconded—"That whereas last year a resolution was passed in favour of the medical education of women in the University; and whereas it is found that under the present regulations of the University Court such education is practically impossible, the General Council represent to the University Court the desirableness of so far modifying the regulations as to afford to women the same advantages as to other medical students."

Professor Turner, seconded by Professor Lister, proposed a negative motion. Professor Turner's motion was carried by forty-seven to forty-five. (The discussion which took place will appear in our next).

Constitution of the Board of Curators.—The following motion by Professor Calderwood was unanimously adopted :—"That a committee be appointed to consider what changes may be desirable in the constitution of the Board of Curators, to prepare a definite plan, and to submit the same to next meeting, with a view to further steps by this Council."

Professor Simpson's inaugural lecture will be delivered to-day (Wednesday) in the Chemistry Classroom at two p.m.

SPECIAL CORRESPONDENCE.

[letter from our own correspondent.]

Toronto, Ontario, Canada,
September, 1870.

The operation and intent of our Medical Bill ought to be better understood. A great deal of misapprehension exists with reference to its influences and power. In the first place, it establishes a Central Board for the province of Ontario, and that is the only portal through which persons can become *legally* qualified to practise medicine in this Province.

Quebec, however, retains all her old boards and licensing institutions; and because our Bill shuts out her licentiates from Ontario, unless they pass our Board, her graduating institutions and their organs have become our implacable enemies.

In the next place, we had in Ontario, prior to the passing of the Medical Bill, six institutions empowered to grant licenses or degrees on behalf of the orthodox profession, besides the Homœopathic and Eclectic Boards.

The licentiates of the two latter boards were entitled to all the privileges and immunities which the law conferred upon the licentiates of the six former, but the Ontario Medical Act completely abrogates the licensing power of the whole eight. The medical degree is now, therefore, simply honorary, having no connection with, and not commanding the licences, nor do the licences command the degree, the latter being obtainable only by an examination before examiners appointed by the several graduating bodies.

With reference to the homœopathic and eclectic classes a great deal of misapprehension and misrepresentation exist. The Profession, generally, opposed their introduction, but since these sects have been brought so completely under the influence of the Council by the Bill, many persons think it has been a good thing for the Profession, as well as for the people. They are so completely under control that not one person has passed as a homœopath or eclectic since the passage of the Bill.

Formerly, many timid and imperfectly prepared candidates preferred going before these boards, because, as they said, they could get through much easier, and when they obtained their license they could practise whatever system they liked, and nobody would know what board they had passed.

It is said by some that our Bill makes them all members of the regular profession by making them members of the College of Physicians, &c., of Ontario, but it does nothing of the kind. The term "Member of the College of Physicians and Surgeons, Ontario," signifies nothing more than the old term, "Licensed Practitioner," by which homœopath, eclectic, and orthodox were all equally known before the passing of the Medical Act, and moreover they must all now register the system or sect according to which they wish to pass or practise, thereby maintaining the distinction between us as broadly as ever, while the Register which was formerly kept in the Provincial Secretary's office at the capital, is now periodically published, and sold in the most public manner, so that everybody may know who is regular and who is irregular.

The meeting in the Council requires no recognition of the principles of homœopathy or eclecticism, or any discussion of their peculiar dogmas.

The members of Council have simply to carry out the law, insist that certain examinations be faithfully undergone, that students pass honestly through a certain curriculum, which they have the power of making as stringent as they please in all departments, save the preliminary which is fixed by law. The members of Council and members of the Profession are not required to, and do not, recognise or meet homœopaths or eclectics, any more than they did prior to the existence of the Medical Act.

We feel that while we cannot strike the sects out of existence, they having been (improperly) recognised by law here for many years, we have them so completely under *our* control, as long as the present Bill exists, that they cannot flood the country with *illiterate* members as heretofore, and we believe that while we accord them the privileges of passing and registering as homœopaths and eclectics, that comparatively few will claim that *privilege ??* when *all* have to come up to a certain equal standard and pass the same examination on so many branches held in common.

Some defects exist in the Bill, particularly in the penal clauses, but these will be remedied in time, but the principal features of the Bill, the one portal for all, we intend to hold on to if possible.

As you are all engaged in the effort to secure a new Bill, giving the Central Board, I have thought it might prove of some interest to know something of the spirit and interest of our Act, about which so much bitterness has arisen.

As the sects are not legalised with you there is not likely to arise the same difficulty as with us. We could not get rid of them, and hence accepted the Bill, which brought them under subjection.

New Preparations.

SYRUP OF THE LACTO-PHOSPHATE OF LIME.

The French, in their days of peace, had brought pharmacy to such a state of perfection that the Parisian *Pharmacien* was a man of importance, and his preparations were frequently sold and prescribed amongst the English Profession. The inventive faculties of the pharmacist, although frequently abused, more frequently showed the marked culture that they had received in their art. The *Codex* of 1866 shows evidence of these remarks—although, in that work, they do not always steer clear of what might be called the gastronomic department of medicine.

Nine-tenths of the pharmacy of this country, unfortunately, consists in advertising nostrums and secret medicines, in which no art is used except in carrying on a monster system of puffing. Outside the question of the relative merit of the individual preparation over others, all such preparations as the above syrup deserves careful trial, and every encouragement to its originator. Its name speaks for itself, and the compound is based upon a sound and scientific construction. M. Dusart, of Paris, says that phosphate of lime is the natural exciting agent in the functions of nutrition, that it induces the albuminoid matter to assume the cellular shape, and that it controls the formation of tissues. When animals are made to feed much upon the phosphates they absorb more food, and increase rapidly in weight, owing to the transforma-

tion of the albuminoid matter contained in the food into muscular fibre.

As regards the chemistry of the lacto-phosphate of lime, the actual composition is probably not known. Pure and recently precipitated phosphate of calcium is, however, perfectly soluble in lactic acid, or what comes to the same thing; lactate of calcium is soluble in an equivalent quantity of phosphoric acid. Lactic acid, or *milchsäure*, as the Germans call it, may be viewed as one of the chief acid secretions of the human body, therefore, if phosphate of lime, which is an insoluble salt, has itself any therapeutic value, it is probably due to the fact that this lacto-phosphate, or a similar compound, must be first formed in the animal economy before it is first assimilated. The syrup, as made by Dr. Evans, of Dublin, is a palatable and elegant form of exhibiting this salt of calcium, and it is only pleasantly acidulous.

VERIFICATION OF CERTIFICATES IN DUBLIN.

The following important regulations have been promulgated since our last issue by the Medical Registrar of the University of Dublin :—

Trinity College, Dublin, School of Physic.

Regulations Respecting Certificates for Medical and Surgical Degrees.

1. In future, all Certificates of Lectures, or Hospital Lectures, must state the Attendance of the Student; and no Certificate of Lectures or Hospitals will be accepted for Degrees in Medicine or Surgery which does not guarantee the following *minimum* Attendances :—

1. Winter Course	. .	42 Attendances.
2. Summer Course	. .	30 „
3. Hospital Lectures	. .	48 „

2. Candidates for the Degree of Bachelor in Medicine are required to produce, in addition to the General Hospital Certificates, a Certificate of Personal Attendance on Fever Cases; such Certificate to be signed by the Clinical Physician under whose superintendence the Student took charge of the cases, and to contain the names, addresses, dates, and nature of Fever, of the several cases.

N.B.—Blank Forms of Fever Certificate will be furnished to the Hospital Physicians on application to the Medical Registrar of Trinity College, Dublin.

11th October, 1870.

The second proviso of the foregoing was received by many of the hospital physicians and surgeons of Dublin with much dissatisfaction, and immediately on its being made public, it was resolved that a public protest against it should be made. Accordingly, the following circular note was forwarded to the physicians and surgeons of the Dublin Hospitals :—

"Sir,—You are requested to attend a meeting of the Physicians and Surgeons of the Clinical Hospitals of Dublin, on Thursday, the 27th instant, at the Royal College of Surgeons, at four o'clock, p.m., to take into consideration a notice issued by the Board of Trinity College, Dublin, on October 11, 1870.

"Your attention is specially directed to the second paragraph of the notice, of which a copy is enclosed.

"Albert J. Walsh.
"Charles Benson.
"Alfred Hudson.
"Henry H. Head.
"Thomas Hayden.
"Samuel Gordon.
"Francis T. B. Qninlan.
"Stephen M. Mac Swiney.
"Henry Eames.
"Thomas W. Grimshaw.

"24th October, 1870."

In response to this notification a meeting was held on Thursday last, at which all the signatories and a considerable number of the medical men of Dublin assembled. A resolution was moved by Dr. Head, denunciatory of the second regulation, on the ground that it impugned the veracity of hospital physicians, and was an unwarrantable interference with the privacy of patients. After some discussion the resolution was adopted.

It is, in our opinion, a very laudable object in the Board of Trinity College to make the attendance of students at their Hospital a reality and not a pretence. It would be disingenuous to represent that Hospital attendance is necessarily what it professes to be, or that in a large number of instances it is other than a deception, or that clinical or lecture certificates are reliable testimony of the diligence of the student. It is quite proper, to our mind, that a University should impose such restrictions with the view of preserving the purity of its degrees, and we are assured that the necessity of some such regulation is well recognised by Hospital Physicians, and the necessity for its enforcement against idle students or inconsiderate teachers well understood.

The Physicians of Dublin Hospitals are, nevertheless, to our mind, quite justified in protesting against a system of surveillance alike impracticable and unfair.

If the Board of Trinity College sees fit to require that each Hospital Physician shall personally pledge himself to the accuracy of the number of attendances, they ask as much as they have a right to demand, or as any Physician is bound to give, and any detail of names, addresses, dates, and diseases of the patients would afford no higher guarantee, and such requirement would dishonour the gentleman to whom it referred, and leave their practice open to a very objectionable examination.

We understand that the objectionable portion of the second clause has been withdrawn, and the Board has thus manifested its feeling that it was impracticable and unnecessary.

THE DUBLIN INTRODUCTORIES.

The schools and hospitals of Dublin inaugurate the session this week. On Monday Dr. Mapother delivered a most interesting address on American Medicine at St. Vincent's Hospital. The prizes were distributed at Steeven's Hospital, and Mr. Morgan opened the session at the College of Surgeons, on Tuesday, Dr. Little delivered the Introductory at the Ledwich School, and Dr. Hewitt at the City of Dublin Hospital; to-morrow Mr. Hayes will address the students of the Mater Misericordia Hospital, and Mr. Tyrrell those of the Catholic University, and on the following Monday, Mr. Martin and Mr. Richardson, will open the session at the Meath and Adelaide Hospitals. We hope to present our readers with abstracts of these addresses next week.

CONFERENCE OF THE IRISH LICENSING BODIES.

We learn that a resolution has been adopted by the Fellows of the Kings' and Queens' College of Physicians in Ireland, which declares it is desirable in regard of the probability of approaching legislation on medical matters, that a conference shall be held of the several Universities and other Corporate Bodies in Ireland authorised to

grant degrees or licenses in Medicine or Surgery, with the object, if possible, of laying down principles or views as the united opinion of several bodies. In accordance with this resolution the several licensing bodies in Ireland have been requested to name three delegates, and the 7th of November at 4 o'clock, has been named for the first meeting. The Royal College of Surgeons has, we understand, decided to co-operate in the movement, and the Council has named the President, Dr. Walsh; the Vice President, Dr. Wharton and Mr. Macnamara to represent the College.

Correspondence.

CHLORAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I quite agree with a "Dublin Physician" (Oct. 19th), in looking on chloral hydrate as an over-rated medicine, and have been disappointed frequently in its action; yet it has done me good service, and I would be slow to join in such a sweeping denunciation as his of all that is new. This very week I got six hours' good sleep for a patient with this chloral hydrate, where morphia and black drop had proved injurious.

He asks, what about podophyllin, pancreatic emulsion, carbolic oil, carbolic silk, carbolised ligature? I will try and answer him. Any careful clinical observer will tell him that podophyllin has valuable properties, but that it requires tact, knowledge and judgment, to turn them to account; that pancreatic emulsion in a great many cases is still proved to be of great value; that the value of carbolic oil, carbolic silk, &c., is still great, and would be greater were it not for the care, patience, and zeal, required in those who use them; and that all these remedies will in twelve months and twelve years maintain their place on the shelf of the man who will exercise judgment in their use, without letting himself be carried away by the zest of novelty, to setting undue value on them, or any other therapeutic remedy. Be slow to receive, yet try every newly proposed remedy. Let your trial be careful and impartial, and the value being found estimate it accordingly.

I am, Sir, yours, &c.,
Jas. Martin, M.D.

Portlaw.

THE WOUNDED IN THE WAR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Some weeks ago ago I sent a short note to you, which I received from my son who went out to attend on some of the wounded in a Prussian town, intending to have followed it up by any communication, which he might send me, but in the performance of his duties he caught scarlatina which prevented him with furnishing me with much interesting material. He now writes—"Our wounded here, about two hundred in number and forty in a neighbouring village, are nearly all recovered. There has been only four deaths, one of which might have been avoided had the patient submitted in the first instance to have the tracheal artery tied, or to amputation at a more advanced period. In Dusseldorf and Cologne erysipelas, typhus and hospital gangrene have been rife, and the mortality after amputation very great, but the patients are now being moved into hut hospital and tents. The government, by some strange stupidity, have refused to send any more patients to the small town hospitals, notwithstanding the good result that has been had up to this in these institutions. They say to avoid confusion, but it appears to me to be a more likely way to incur it.

"As to your question, most of the wounds are in the upper extremities and on the left side. I can tell you nothing of wounds inflicted by the needle-gun, having seen none but those caused by the chassepot. The latter does not seem to me to cause severe wounds, the balls being easily diverted from their course, and not shattering bones except they impinge straight upon them. The mitrailleuse ball is larger, and the wound from it, of course, more severe, but not differing in character. When three or four, however, strike a limb it is thoroughly shattered. The wounds, however, inflicted by pieces of shell are the worst and most difficult to heal. There is great difficulty in inducing the patients to submit to free ventilation in the wards, and it is a delicate matter to deal successfully with the prejudices of the country. I find the patients, however, very grateful, and on my first visit to the hospital after my recovery, I was received with warm expressions of their pleasure at seeing me again. I will shortly move on towards Strasburg, and see what is doing, and then perhaps may join some of the large hospitals in Dusseldorf or Cologne."

I am, Sir, your obedient servant,
J. Martin.

THE "MEDICAL PRESS" AND INDEPENDENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You denounce, in your "Notices to Correspondents," my communication as libellous—which it is not, but a truthful *ex parte* statement on an important professional topic—and with your charming air of independence, fear to insert it. Your correspondents cringe to your independence, and worship your impartiality. Is your refusing my letter publication a fair sample of that independence and impartiality?

I am, &c.,
Cantharides.

October 17th, 1870.

*** Your letter, in the form in which you sent it us, is certainly libellous; but you will find us as independent as you are yourself. If, then, your statements be accurate and just, append your name, and give us an implicit undertaking that, printing your letter, you will take all the responsibility of it in case of after proceedings. We have neither the time nor the inclination for making ourselves a scapegoat for lawyers over a trivial matter. Nevertheless, regardless of your letter, we do claim for these columns independence and impartiality. —[Ed. M. P. and C.]

BABY-FARMING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Will you permit me space to make a few concluding remarks in reply to the letter of "Veritas," published in your present issue? He tells us that he has been connected with an institution which admits many hundreds of "*victims to seduction*" annually, and at once then claims attention for his strictures. Where are his statistics to prove that the seducers of women "*are women and dress?*" The essence of "Veritas'" letter, as far as my humble comprehension goes, is to prove that men do not seduce except on very rare occasions, but that one girl makes the preliminary arrangements for the destruction of her female friends. What will "Veritas" say to the following, from the *Times* of Monday?:—

"At Southwark, a respectable-looking young woman, 30 years of age, was placed at the bar, charged with being found destitute in the public street, creating a disturbance, and refusing to leave the steps of a house in Blackman street. Police-constable 142 M said that between 11 and 12 o'clock at night he found the prisoner sitting on the step of a door in Blackman street, screaming. She said she had been ejected from the house and would not go away. He was compelled to take her to the station-house, when she gave the following account of herself to Inspector Fox, who took her statement down in writing:—'I am a native of Weymouth, where my friends reside. About twelve months ago, an insurance agent courted me and decoyed me from my home under the promise of marriage. We came to live in Trinity square, Borough, as man and wife. My family are respectable and in independent circumstances. The man obtained large sums of money from me, and when I pressed him to marry me I found he had a wife, and he turned me out. His wife died two months ago, and on the night in question I went to his house to know what his intentions were towards me, when he called a constable to eject me. I do not want to injure him. All I want is to die on the doorstep. If you let me go, I shall go back and lie there till I die. I went to a chemist in the evening, and had he supplied me with what I wanted I should have been dead by this time, and all my sorrows forgotten.' The magistrate asked if the prisoner was sober. The constable replied that she was, but was very much excited. In answer to the charge, the prisoner said it was quite true what

the inspector had taken down. She was seduced under promise of marriage, and she was ashamed to go home to her friends. She would rather die in the streets. The magistrate directed the constable to take the prisoner to the office of the Rescue Society and see what could be done for her."

What does he say to the handkerchiefs marked with coronets, to the wicked Earls, to the Chancery barristers, to the well-known gentlemen of another profession, commented upon by our powerful ally, the *Pall Mall?* Not always women tempters and seducers in dress!!!

If I don't compliment my neighbours, it is because I cannot; and I take his sneer for what it is worth respecting the country which supports me. I work for that support. "Veritas" asks "What is said about married women who leave their husbands or deceive them?" Poor Captain Vivian, or, better still, the virtuous Marquis, *et hoc genus omne*, can answer this better than I.

I cannot accept as truth the literal translation of "Veritas," unless he brings to bear statistics to show, that "women and dress" are the seducers in greater proportion, and that the men, as a majority, are innocent.

I do tell "Veritas," very honestly, very plainly, and without umbrage, that there does exist such systematic monsters as men-seducers, who live to betray and to destroy, and I am rather astonished his experience is so limited as not to know it too.

In the communication of "Prudentia et Justitia," I am very proud, if I judge aright the valued source of the letter, to find so clever, so enlightened, and gifted an authoress with me on the point of making seduction a criminal act, and ascribing it as the foundation all of abortion-mongers, infanticide, or baby-farming, call it what you will. Dr. Green, in a letter addressed to the editor of the organ of the British Medical Association in reply to Dr. Drysdale's communication, also requires seduction to be made felonious.

In conclusion, with regard to making seduction a criminal act, I may apply to "Veritas" the following words, contained in an article written in *The Saturday Review* a few weeks ago, and adapted to the case of Margaret Waters:—"Criminal law, after all, only embodies morality. If a criminal says that he has no evil intention, it may only be because, in fact, he has no sense of morality. What the law says is,—We regard not your views of morality or your intention, but we act upon what mankind has agreed to consider morality." What is "Veritas'" sense of morality?

I am, &c.,
J. Waring-Curran.

Osman House, Sutton-in-Ashfield, Notts,
Oct. 27th, 1870.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In May Dr. Hanrahan, of Castletown, Mountrath, sent me £5, the amount of subscriptions collected by him for the Medical Benevolent Fund Society. This sum was duly added to the funds, and appears in the auditor's abstract as subscriptions from Queen's County; the list of subscribers has not, however, I find been printed in the report; I hope you will be so good as to publish it, and, at the same time, permit me to acknowledge £1 1s. from Dr. Darley, of Coolock, which only reached me to-day, but was sent by that gentleman some time ago, and should have appeared in the report.

I am, Sir, yours truly,
James Little, Treasurer.

Queen's County Branch Subscriptions for 1870.

Dr. Fisher, Mountrath, £1; Dr. Percival, Stradbally, £1; Dr. Hobson, Ballylinan, £1; Dr. White, Borris-in-Ossory, £1; Dr. Hanrahan, Castletown, £1.—Total £5.

Civil Surgeons for the German Army.—The German Secretary of War has called upon civil medical men to join the Hospital Reserve of the Army. Surgeons are more and more needed among the invading troops. The *Allg. Centr. Zeit.*, gives a list of medical officers who meet with wounds or death during the campaign.

Medical News.

Royal College of Surgeons.—At the special meeting of the council on Thursday last, the 27th Oct., the following gentlemen were elected members of the Court of Examiners, in the vacancies occasioned by the resignations of Mr. Richard Quain, F.R.S., and of Sir William Fergusson, Bart., the President of the College, and by the expiration of the term of office of Mr. F. C. Skey, C.B., F.R.S., who declined being put in nomination for re-election: Mr. Henry Hancock, Vice-President of the College, and Senior Surgeon to the Charing-cross Hospital; Mr. Frederick Le Gros Clark, Surgeon and Lecturer on Surgery to St. Thomas's Hospital; and Mr. William Scovell Savory, F.R.S., Surgeon and Lecturer on Surgery to St. Bartholomew's Hospital. Mr. Gray has given notice of the following motions, which will be considered at the Council meeting of Nov. 3rd:—1. That, in the opinion of this Council, the Royal College of Surgeons of England, is entitled to a greater number of representatives in the General Council of Medical Education and Registration of the United Kingdom than that which is assigned to it by the Medical Act of 1858. 2. That, in any increase of the number, provision should be made that one, at least, of the representatives of the College should be elected by the Fellows and Members. 3. That a copy of the foregoing resolutions be forwarded to the Lord President of the Privy Council.

Natural Science at Oxford.—The following lectures are to be given this term. 1. University Lectures: Professor Phillips, F.R.S., "On the Composition and Structure of the External Parts of the Earth." Professor Lawson, "On the Minute Anatomy of Plants." Professor Rolleston, F.R.S., "On Anatomy and Physiology." Professor Pritchard, F.R.S., "On Astronomy." Professor Clifton, F.R.S., "On Elementary Statistics," and a continuation of his lectures "On Heat." Mr. Wyndham, for the Professor of Chemistry, "On Elementary Principles of Chemistry." The Professor of Zoology will give assistance to all who are working at the Articulata, the collection of which he is arranging. All these are free public lectures, and are illustrated by experiments, and are all largely attended. 2. College Lectures, &c.: Mr. A. V. Harcourt, F.R.S., Lees Reader in Chemistry, "On the Chemistry of the Metals," at Christ Church. Mr. A. W. Reinold, Lees Reader in Physics, "On Hydromechanics and Heat," at Christ Church. Mr. J. B. Thompson, Lees Reader in Anatomy, "On Comparative Osteology," at Christ Church. Mr. Heathcote Wyndham, "On Chemical Philosophy," at Merton. Mr. Abbay, "On Elementary Physics," at Merton. Mr. Chapman, "On Anatomy and Physiology," at Magdalen.

Unhealthy Dwellings.—Much has lately been said about the unhealthy buildings occupied by the labouring classes. Public opinion in Lincoln has lately been directed to the state of the dwellings of the poorer classes of society by the Government enquiry, and the publicity given by the press to one particular instance where a working man died of fever, in a house quite unfit for habitable purposes. Now, besides the great power given to Boards of Guardians, Town Councils, &c., by the Sanitary Act of 1866, there is an Act to provide better dwellings for artizans and labourers, called "The Artizans' and Labourers' Dwelling Act, 1868," which enables local authorities to demolish such places as are unfit for habitation if the defects in any premises cannot be remedied by structural alterations and improvements or otherwise. It cannot be denied that there are many houses in Lincoln thoroughly unfit for habitation, yet to demolish these (without providing adequate house-room for those ejected) would be to turn many an honest family either into the streets, or away to seek shelter in country districts, probably far away from the scene of their daily occupations. To demolish these would also bring down upon the local authorities the fierce denunciation of certain tenement holders—the greatest opposers to all improved sanitary measures—who (as a rule ignorant) are fond of airing their fancied eloquence before the public; and whilst announcing the wrongs of the working men, are not above taking their few shillings as rent for places used as habitations, though in many instances unfit for pigsties. It seems strange that the people of this country—a country at peace with the world—a country whose stack-yards and barns are overflowing with the abundant harvest the Almighty has been pleased to

provide, a country whose philanthropy has lately sent abroad hundreds of tons of clothing, and hundreds of thousands of pounds to succour the wounded and sick of foreign nations—should be content to allow their fellow creatures to be huddled together in houses unfit for habitation. Stranger still, that within a stone's throw of our splendid Cathedral, a human being should be allowed to die of a preventible disease, in a little place, if any better than a hovel, surrounded by all the necessaries for fostering and propagating disease, and with scarcely a rag to cover him.—*Lincolnshire Chronicle.*

Post-mortems at Hospitals.—The Governors of Guy's Hospital have placed in a conspicuous position the following notice:—"*Notice to Friends and Relatives of Deceased Patients.*—The Governors reserve to themselves, in the interest of the public and as one of the conditions of admission to the hospital, the right of causing a *post-mortem* examination to be made of the body of every patient who dies within the hospital, by the Pathologist or his representative, for the purpose of accurately determining the causes of death. In the event of the friends or nearest relatives being opposed to such an examination, they are to communicate their wishes to the Superintendent, who will submit their objections to the medical officer who had charge of the deceased patient, and if he is of opinion that there is no urgent need for a *post-mortem* examination, the Superintendent is authorised to dispense with it.—Jno. Chas. Steele, Superintendent."

The Guards.—According to the *Army and Navy Gazette*, Staff Assistant-Surgeon W. Collins, M.D., has been selected to fill the vacancy amongst the medical officers of the Brigade of Guards caused by the death of Assistant-Surgeon H. Turner, Scots Fusiliers. Dr. Collins, it will be remembered, took first place at the competitive examination of the Army Medical Department in October, 1866. He has since served in Canada, and was recently attached to the 1st Life Guards.

Dr. Bolton, of Newcastle.—A very handsome testimonial was, a few days since, presented to Dr. Bolton, late house-surgeon of the infirmary at Newcastle-on-Tyne, consisting of a framed illuminated address, a silver salver, and a purse containing one hundred and twenty sovereigns.

Mr. Greene, of Morpeth.—The attendants at the Morpeth County Lunatic Asylum, on learning that Mr. R. Greene, the Assistant-Surgeon, was about to take an appointment at the Sussex County Asylum, presented him, on his departure, with a testimonial in the shape of a silver cup, suitably inscribed.

Dr. Wallace, of Trim.—On the 10th ult., a deputation of gentlemen of Trim, waited on Dr. Wallace, to present him with an address and testimonial upon his retiring from the office of medical officer to the Trim Dispensary. The testimonial consisted of a superb silver tea and coffee service, from the eminent firm of Waterhouse and Co.

Royal College of Surgeons in Ireland.—At the quarterly examination held on the 19th ult., the following gentlemen passed the preliminary examination of the College,—viz.; William Alfred, John Armstrong, Penrose J. Barcroft, Richard E. Biddulph, Abraham Blundun, George D. Bourke, Alfred H. Bullen, John E. Connelly, William A. Cooper, Eyre S. Dalton, Francis Day, John E. I. Deane, Alexander Dempsey, Samuel F. Dooley, James Doyle, James H. Dunne, Patrick I. S. English, Joshua S. Grubb, Ernest C. Hamilton, Hans L. E. Hamilton, William H. De Burgh Hoctor, John J. Hincks, William P. Hourigan, John C. Kempston, Patrick Kennedy, William Keys, Thomas P. O'Leary, Stewart Partridge, Nicholas C. B. Parsley, Alfred Patterson, Patrick Phelan, John J. Poett, James Ross, Henry A. Sampson, Samuel Sharp, Abbot G. Shelton, George F. Skirving, Edmond Tully, Rueben Turner, Nathaniel Vicary, Patrick F. Walsh, and Lancelot O. W. Weire.—At the quarterly examination held on the 25th and 26th ults., the following gentlemen passed their second and third examination for the letters testimonial, and were admitted licentiates of the College—viz.: Alexander Barber, Robert Barry, Daniel O'Connel Boyle, James B. I. Brady, Samuel W. Brown, Patrick Butler, John S. Carleton, John Clancy, Paul S. Connelly, Charles Little, John G. Little, George W. Mac Ilwee, Patrick J. Macnamara, Joseph W. Neligan, Thomas Reardon, John Redmond, Francis Legravr, William H. S. Westropp, Henry F. L. White, and Thomas Wills.

The Edinburgh Chair of Natural History.—We understand that Professor Wyville Thomson, who for the last eight or nine years, has occupied the chair of Natural History in the Queen's College, Belfast, has been appointed by the Crown successor to Professor Allman in the corresponding chair in Edinburgh University. Professor Thomson is well known in connection with his deep-sea researches. In 1868 and 1869 he was associated with Dr. Carpenter in making investigations into the temperature and animal life at great depths in the North Atlantic, a work undertaken at the request of the Royal Society of London.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

⁂ We must also request our Correspondents to write only on one side of the paper and in *legible* characters. We are often compelled to consign MSS. to the waste-paper-basket merely because it is illegible.

Correspondents not answered in the current Number are requested to look to the Notices the following week.

Inquirer does not state how long the patient lingered, but, from his note, we judge that death was very speedy. In that case the enquiry suggests itself as to whether there could have been any exposure to the contagion of scarlet-fever. There are undoubted cases of that disease which terminate with awful rapidity. The patients seem struck down by the poison and sink at once, before the usual symptoms have time to develop. Similar cases have been noticed in epidemics of diphtheria and other diseases. At the same time, all other causes of rapid death should be considered. It is a pity no *post-mortem* was made.

F.R.C.S. Lond.—Write to the secretary of the University, who will at once give you a reply.

THE LONDON MEDICAL SOCIETIES.

Wednesday, Nov. 2.

Obstetrical Society of London, 8 p.m., Dr. W. Martyn, "On the Management of Childbed with a view to Promote successful Suckling." Mr. Coward (Christchurch, New Zealand), "A Case of Inversion of the Uterus." Dr. Tracey, "A Short History and Description of the Lying-in-Hospital at Melbourne, Australia;" and other papers.

Thursday, Nov. 3.

Harveian Society of London.—8 p.m.

Monday, Nov. 7.

Medical Society, at 8 p.m.—General Meeting.

Tuesday, Nov. 8.

Royal Medico-Chirurgical, at 8½ p.m.

APPOINTMENTS.

Ashe, Isaac, M.B. and C.M., Trin. Coll., Dub., Consulting and Visiting Physician to the Donegal Lunatic Asylum, Letterkenny.

Browne, T., L.R.C.P., House-Surgeon to the West London Hospital.

Buck, T. A., M.B., M.R.C.S., Senior Medical Assistant to the Gloucestershire Lunatic Asylum, near Gloucester.

Crean, R., L.K.Q.C.P.I., House-Surgeon to the Clayton Hospital.

Davidson, A., M.A., M.B., Lecturer on Pathology to the Liverpool Royal Infirmary School of Medicine.

Lee, E. S., M.R.C.S., Assistant House-Surgeon to the West London Hospital.

Mackenzie, S., M.R.C.S., Resident Medical Officer to the London Hospital.

Richmond, S M.D., M.R.C.S., Surgeon to the Northallerton Gaol.

Rigden, W., M.R.C.S., House-Physician to the Hospital for Women.

Saunders, T. D., L.R.C.P., Medical Officer District No. 4 of the West Ashford Union, Kent.

Wilkin, T., L.K.Q.C.P.I., Medical Officer to the Lisbellaw Dispensary District of the Enniskillen Union.

VACANCIES.

Middlesex Hospital.—Assistant Physician. Application before the 15th inst.

Western Dispensary, Marylebone.—The Officers of Physician, Accoucheur, and Surgeon in Ordinary. Application for either appointment by the 7th inst.

Liverpool Southern Hospital.—House-Surgeon. Salary £100, with board.

West Sussex Infirmary.—Surgeon. Election on the 17th inst.

Liverpool Royal Infirmary, School of Medicine.—Lectureship on Comparative Anatomy and Zoology. Application by the 5th.

Stafford Infirmary.—House-Surgeon. Salary £25, with board, &c.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A System of Surgery. Fifth Edition. By Sir William Ferguson, Bart., F.R.S. London: John Churchill and Sons.

An Introduction to the Osteology of the Mammalia. By Wm. H. Flower, F.R.S., F.R.C.S. London: Macmillan and Co.

A Book about Shams. By Dr. Lory Marsh. London: Ward, Lock, and Tyler.

Introductory Lecture

ROYAL COLLEGE OF SURGEONS, IRELAND.

SESSION, 1870-71.

INTRODUCTORY LECTURE DELIVERED BY MR. MORGAN, F.R.C.S.I.,

Professor of Surgical and Descriptive Anatomy, &c.

THE PRESIDENT OF THE COLLEGE IN THE CHAIR.

AFTER some introductory observations, Mr. Morgan proceeded to say:—The splendid success of the Associations for the "Relief of the Sick and Wounded" speaks volumes for the kind and anxious feelings of the general public to soothe, in even a small degree, the miseries entailed. Yet, what are its efforts as compared with the sacrifices made by members of the medical services, where not merely the aid of the medical skill is so taxed, that we hear of twenty hours out of twenty-four being occupied in active attendance by the surgeon, but the personal risks also of danger on the field, and the greater ones arising from epidemic influences are disregarded in the excitement incidental to the "circumstance of war." These conditions have been beyond doubt most trying and harassing, yet do we ever hear of the members of the medical staffs failing in their duty? When urgency is appealed to, do we read of those who have volunteered their services sparing themselves, or neglecting their dying and suffering fellow creatures? No, gentlemen. We are surely entitled to say, without fear of contradiction, that our profession has never been accused of remissness, where suffering was to be allayed, or where in sudden and appalling emergency from war or epidemic inroads, its members have been called on to aid the State or the public in combating the woes such afflictions necessarily entail. We read such paragraphs as the following constantly in our medical journals; I will take a recent one—"Amongst the victims of the war, we regret to announce the decease of Dr. Rigaud, resulting from over fatigue in attending on the wounded. M. Rigaud was well known in the south of France, and his untimely death will be deplored by all who knew him. He went, on the outbreak of the war, to serve his wounded countrymen, and laboured among them with such devotion as to sacrifice his own life." Such incidents as these are frequent. So accustomed do we become to them that beyond a passing tribute of praise and regret for one who deserved so well, we enroll the name as another in the long list of those who when duty called, or the noble nature of his sentiments were appealed to, literally "worked himself to death," to aid his fellow man —*ex uno disce omnes*. Yet such examples can be too frequently reiterated as, both here and abroad, our fever and cholera epidemics testify. Again, we read as a professional episode of the war, that 500 surgeons fought at Sedan, leaving 200 of their number in the field; while we must give every credit to these for personal courage and *élan*, yet I think you will agree with me, that the epitaph "Died from over-fatigue in attending on the wounded," stands in monumental simplicity, as one preminently suited to a member of our order, fallen in so good a cause. Indeed, the most attractive feature almost in our profession, is the happy combination of the pursuit of a science with the sympathetic sentiments engendered by fellow feeling with our own fellow creature. The necessary relation of the conditions of mind and body is a subject which never fails to give *verve* and interest in the exercise of our art. Let us take examples, just now too frequent, and I doubt not most potent emotional stimulants to exertions in the ambulance hospitals. We read in the newspapers of so many thousands being wounded, they seem as nothing in proportion to the slain, but each of these have, with anything of a serious wound, gone through a stage known to surgeons as "*the shock of an injury.*" Picture to yourself a young man, healthy, vigorous, full of life, energy, courage, and determination—he is struck down, he falls disabled, and then ensues the shock to his nervous system. He is directly brought in pale, all but pulseless, insensible, and faint, presenting in its details the appearance so well

depicted by the artists to our illustrated newspapers. In proportion to the intensity of this appearance of shock, are our sympathies awakened. I am myself pretty certain that nothing has done more to soften the heart, and lead to a responsive result with the public, than these graphic, silent, but irresistible appeals in the journals—all of them, no doubt, taken from reality. The abjectness and total dejection of the sufferers, the accompaniments of crowding, hurrying, and emergency, are made familiar to all. The presence of the clergy to sooth those whose shock is probably irrecoverable, and the tender assiduity of the volunteer nurse are all carried out with faithfulness and attention to detail. If these affect and rouse non-professionals, and those who are ignorant of the true significance of the expression and "*the shock of an injury*, what will it be with the surgeon. Not only will his feelings, as a human being, be as acutely influenced as others, but it will be his important duty to gauge the extent of his danger, to judge how far the shock is irremediable, to pass the painful verdict—mortal ; or, whisper the hopeful one—recoverable. Now, in the deciding of such important questions, I need hardly tell you the greatest perfection of our knowledge is needed, and the most accurate acquaintance with the principles of our art is most essential, combined with that self-reliance which can only be assured the surgeon by perfect self-confidence, and a consciousness of his possessing *within himself* the resources necessary for any emergency. From these exemplifications of the important demands on the surgeon's knowledge, acquirements, and judgment, which may arise at any moment, the question very naturally arises in your mind as to how you may best become masters of that art, which can be of so great utility to our fellow man, and which can, humanly speaking, preserve so many valuable lives, and relieve so much suffering— where by the well trained hand of the surgeon, the knife can be guided with certainty, or the physician skilled in the laws of hygienic aids, meets the inroad of epidemics themselves more fatal than the clash of armies, and seeks to combat the malignant influence of infections by which camps, cities, and even whole countries have been devastated. No doubt, the question is a very interesting one for you how you will best become an adept in an art such as this, by which if we cannot always cure, we are happily enabled to alleviate the all chastening influence of pain—a power from which "in all its sad variety" neither wealth or poverty can hope for exemption, and which forms the great bond of sympathy between all classes. I shall, therefore, endeavour succinctly to explain to you, how you will best proceed to attain your end. The institution in which we are now assembled has always directed its best efforts to carry out such a truly efficient mode of education and training as would best serve the interests of the public and the State ; and would best sustain the character which has marked its conduct from its earliest date, in providing "properly educated surgeons."

The Charter granted to this College by King George Third, sets forth its objects, and reflects credit on its members, *even at that early period*, in establishing it as an institution for the improving of the Profession of Surgery. From thence, it has had but the one object in view, and, from time to time, has modified its method of education, as best would suit the necessities of the public and the Profession.

Now, with the incoming year, the additional test of clinical examination has been added in conformity with the wishes of the public, and of the Profession at large.

The number of licentiates on the roll of the College now amounts to over 2,000. They are spread over the face of the world. In the memorable expedition of the "Fox" to the Arctic Regions the health of that heroic crew was entrusted to a licentiate of the College. Just now, the Chef d'Ambulance at Sedan, who has reflected so much credit on Irish Surgery, is a F.R.C.S.I. The Crimea, India and the Colonies have acknowledged the services of our members ; and I may ask, can anything testify more to the care taken by the College in perfecting a practical and careful training for the Profession of Surgery, and the carrying out of its charter, than the success of the services rendered by the Poor-law Medical Officers throughout Ireland, amounting to about 1,000, the vast number of them having been *alumni* of the institution in which we are assembled. "Surely, we have done the State some service," and have not betrayed the trust confided in chartering an Institution for the "Improving the Profession of Surgery," when such men have been supplied for the public as have succeeded, by increasing care and precaution, in so far combating, as absolutely to banish the terrible scourge of small-pox from this country. Such is the success of the vaccination system, that small-pox is now actually unknown in Ireland—in perhaps no country in the world is the medical relief of the poor so efficiently carried out —or have the medical officers been more remarkable for assiduity and self-disregard.

A return has been recently presented to the House of Commons which compares the number of deaths in the three kingdoms, and classifies them under various headings. The main result may be inferred from the simple statement that to bring the deaths of Ireland up to the level of England or Scotland, some 301,000 more persons should die annually in that country ; or, we may say, that, taking the last year in the return, 1868, the number of deaths in England to every million of population was over 22,000, and in Ireland under 15,000. Taking, again, the number of small-pox cases, we find that in England the number fell off considerably during the years 1864 to 1868, the deaths attributable to that disease being 7,684 in the first of these years, and only 2,052 in the last. In Ireland, however, the case was far more remarkable. There were 854 deaths from small-pox in 1864, and only 23 in 1868.

It is plain that the maintenance of the health of the inhabitants of the rural districts of Ireland is absolutely dependent on the efforts and talents of the Poor-law Medical Officers. On the 7th April, 1861, the day on which the last census was taken, there were 46,141 persons sick at their own homes in Ireland, or about 50 persons sick at their own homes on that day to each of the dispensary medical officers. The average population under each medical officer's charge is 7,400, or as a sixth of the population are attended by the dispensary doctors during the year, the average number attended by each will be over 1,200. Such results speak for themselves. Again, we find from a non-medical source the highest testimony incidentally paid to the benevolent and indefatigable efforts of members of the Poor-law Medical Service.

Mr. Trench, in "Realities of Irish Life," gives the following graphic account of some incidents of his visit with the Doctor at the time of the famine fever. In one house which I entered Dr. Sweetman proceeded to a dark corner, and feeling with his hand, told me there were six in the bed—father, mother, and four children—all unable to rise. I was particularly struck with the question put to the poor people by the Doctor—Are there any dead here? In another house, four in fever ; in another, father dead, wife and daughter alive. In another house—"a dying man and woman, and a boy with dropsy." It would be unnecessary to quote further proof of the ability, devotion, and self-sacrifice of the members of the Profession and of this College, who occupy positions so important to the community as the Poor-law Medical Officer's. The amount of good done, of ready help, and perfect medical aid afforded, is incalculable, reflecting such credit on this Institution and its members that, on an occasion such as this, I could not omit, on the part of this College, referring to these practical results as entitling it to the combined confidence of the State, and as deserving the gratitude of the public.

Education.—The tripod—I may so express it—of surgical education on which this College has based its system, is formed of Anatomy, Physiology, and Surgery, as being the great essentials. Indeed, the relation of surgery to anatomy is so essential that at all times anatomical studies

have formed one of the great anxieties of the Profession, and the State has arranged such facilities for its study as will render it unpardonable in you, gentlemen, not to be expert and thoroughly conversant with its details, and you may be convinced that your first and greatest attention should be paid to its acquirements—it is a study which must be steadily pursued—with perseverance you will master its details.

Original Communications.

ON THE FORCIBLE INTROSPECTION OF WOMEN BY GOVERNMENTS.

By Chas. Bell Taylor, M.D., F.R.C.S.E.

Mr. Holmes Coote, the well-known Surgeon to St. Bartholomew's Hospital, remarks—"That the philanthropist who would attempt to deal with prostitution on other principles than those of Him who uttered this warning and advice, 'Let him that is without sin amongst you cast the first stone,' must needs be both a bold and ignorant man; bold, because he attempts in defiance of such warning to do that which has failed in every known clime and age; ignorant, because he has yet to learn that in the sight of their Maker men and women stand with equal rights, and that no blessing will attend legislation which presses unequally on one sex to the supposed advantage of the other." As I entirely concur in these views I shall, with your permission, first question the right of the State to interfere for the prevention of venereal disease by the forcible introspection of women. There are certain natural rights belonging to every woman, even the most outcast, that, in my opinion, men born of women are bound under all circumstances to respect. The attempt to enforce such laws as are embodied in the Contagious Diseases Acts of 1866 and 1869, will assuredly fail in their professed object, and undoubtedly tend, in many ways, to injure and weaken the Government that sanctions them. I make these observations with the more confidence because, as I am informed, a British Parliament is the first legislative assembly in the world that has ever legalized such violations of the person, and because it is clear these Acts were smuggled through the House under a misleading title, unknown to the constituencies, and unknown to the vast majority of members themselves.

I am quite prepared to admit that, in times of great public danger, in cases of sudden pestilence, or when from various causes a large portion of the population, for no fault of their own, are threatened with calamity, that a pure despotism may not only be needful, but ought to be tolerated by a free State; but three essentials are requisite. In the first place, the necessity must be undoubted; in the second, the law must be limited to the shortest possible period; and above all, it must be impartially applied—not limited to one sex only. The Editor of the *Medico-Chirurgical Review* remarks—"Even where considerable danger exists to a section of the population, against which it cannot protect itself, legislation ought to be slow to interfere—where the dangers apprehended arise out of those natural Divine Laws which affix trouble, or even death, as the penalty of transgression." That these penalties extend beyond the first transgressor is not a circumstance that will warrant the exceptional intervention of the State. It is not venereal affections only, but all kinds of calamities—the penalties of sin or folly in a parent that are visited on his children and connections. "It must be admitted," says Mr. Simon, "that the living a loose life, and catching disease, are private voluntary acts, from which no citizen has any right to call upon Government to protect him." If it be urged that the evil does not stop with the first sufferer, but may spread to the innocent, the same may be said of every misdeed and misfortune; and to constitute grounds for State interference it must be shown, *First*, that the damage done by venereal disease is so gigantic as to altogether over-rule the sound general policy of non-interference; *second*, that such interference would be, at least, effectual (which is positively denied); and *third*, also that the good to be attained would be worth the cost.

The Association which has been formed to extend this Act to the whole of the women of this country, holds that sufferers under any kind of contagious diseases, are dangerous members of society, and should be prevented from communicating their maladies to others, which is a very simple and easy method of settling the whole question.

But let us consider for a moment—if we admit this principle, where is it to end? We must seize and shut up every man, woman, and child affected with any kind of contagious or infectious malady. We must separate the seriously ill or dying husband from the wife; the sick wife from the husband; children from their parents and friends; break up all familiy ties in times of misfortune and affliction, and at moments when they are most needed and most endearing. The author already quoted remarks that, "Even confining the question to venereal diseases, are we prepared to allow the interference of the State? Can we bring ourselves to imagine the State interfering in the case of every man, woman, and child, to prevent the extension of these diseases to others?" The Association, previously referred to, places no limit nor condition upon the duty of the State in preventing contagious diseases. Let us try and put this straight. Two principles may be laid down upon the basis of which the question of State interference may be answered; for it is obvious that a population of Englishmen are not to be treated as children who are entirely unable to take care of themselves. And the first principle of British legislation may be thus expressed, that the State shall only interfere where there exists a considerable danger to a large section of the public, against which the exercise of ordinary care and prudence will not suffice for protection. We may illustrate this by instancing the provisions made by law for the safety of travellers by railway, or by ships, for the disinfection of public conveyances, and generally for the abatement of nuisances upon premises over which the sufferer has no control. Now, it certainly cannot be said that the exercise of ordinary care and prudence will not protect a man from venereal disease. If he deliberately puts his head into the lion's mouth, he is very properly left to take the natural consequences of his folly; and the fornicator has less right to ask for protection because his conduct is immoral, although not legally criminal, and public and private immorality is a state of things against which good government ever sets its face. A gallant colonel, who spoke recently at a public meeting in favour of the Acts, remarked that—"Women had no right to communicate disease"—an *ad captandum* argument. all very well so far as it goes; but it does not go far enough. Surely, *men* have no right to communicate disease, and there is abundant evidence to show that of the two sharers in a common offence, even so far as the spread of disease is concerned, the men (notably soldiers and sailors) are equal, if not greater sinners. Now, Sir, I don't find any mention of men in the Contagious Diseases Acts, which are for women only as distinguished from men and animals. Moreover, the man who deliberately inoculates himself during the commission of an immoral act, is alone to blame for his misfortune. It is not just to say *only* that women communicate disease, as though they had spontaneously generated an affection, which must have been previously communicated by a man, and as though the woman came to her partner without his knowledge or consent, when it is clearly the male who deliberately seeks out the female, and wilfully contracts the malady with his eyes open, and well aware of the risk he incurs. I think, also, Sir, that in apportioning the penalties for this fault, we ought to remember, as a matter of manly feeling, that the man is tempted only by lust, while the woman is constantly urged by suffering, by bribes, by cruel, biting poverty, and absolute want of the necessaries of life. We

are told that women make a trade of their persons, and that Government has a right to regulate trades—in fact, to supervise the persons of prostitutes in order that the fornicator may have a good article for his money. Well, Sir, the trade in question is an immoral trade, and if Government is to avoid implication in its immorality, I humbly conceive that it must avoid, either virtually or actually, licensing or regulating it at all.

In fact, the less Government has to do with prostitution—except in the way of suppression, keeping it within decent limits—the better.

What should we say if a deputation of prostitutes waited on Parliament, demanding despotic and indecent laws to be directed only against men, on the ground that they—the men—communicated disease to them and their children! A sanitary law applicable to one sex only is an absurdity. Let me follow out this trade argument to its legitimate conclusion. There can be no trade without a buyer and a seller. If the trade be infamous, both are guilty; if not infamous, why punish the woman? If you say you don't punish her, then I say that the periodical examination, at the option of police spies, of those who are not diseased is pure torture, and utterly indefensible on any plea. Moreover, in this case, it is clearly the demand which creates the supply, and the male sinner is most to blame. Who pays for the rouge, the finery, and the wine? Who seduces, keeps, abandons, and then indiscriminately patronises these poor women? and who when they turn to honest labour, employs them on starvation wages? Why, Sir, according to the last census, there were 20,000 needle-women in London alone, who were unable to earn more than from two to five shillings a week, and the *Times* of the same period tells us that well-born women were dying from want while making shirts at two shillings a week. Let us not forget while visiting all the penalties upon the weaker—the less erring and more tempted of two sharers in a common offence—that the Eros of our streets is the child not of Venus, but the offspring of misery and starvation. But what shall you say when I tell you that the law is not confined to prostitutes; that it is not limited to the class who are said to make a trade of their persons; but that it entirely abolishes legal safeguards for *all* women, and places the freedom, honour, and sacred personal rights of all (certainly all of humble station) under the brutal control of the lowest executives, whose duty it is to spy—who are disguised in plain clothes—and who make offensive overtures to decent women in order to multiply the number of apparent cases falling within the scope of the acts? No slander is so cruel as an attack upon a woman's reputation, and if you do not share the indignation with which I have read the following scraps of Parliamentary evidence, I have strangely mistaken the noble Profession to which I have the honour to belong. The Chairman of the Committee says to the examining Surgeon:—

"Suppose the police bring up a woman who is a modest woman, surely she would decline to submit?" The reply is—"No, for this reason: the police, acting on their own impressions" (mark the phrase!), "say, if you don't submit, you go before the bench." Let us realise the situation for one moment. A policeman, in plain clothes, takes into custody a respectable girl or woman, and tells her that unless she submits to have her person violated with a surgical instrument, periodically for a year, that he shall take her before a bench of magistrates, and swear that he—the moral policeman!—thinks something; for that is all that is required. In fact, we have evidence to show that they ignore magistrates altogether, and threaten them with three months' imprisonment if they refuse to submit to immediate registration as common prostitutes. Why do these modest women submit? Because they are frightened, ignorant, and friendless. They don't understand the law. They have no counsel to speak for them. They dread the bench and the police; they know that such an accusation before the magistrates means loss of situation and character—in short, means ruin; they know also that they have no chance against the only witness, who is the man paid to accuse them! and we are told that "*they trust instinctively to the kindliness of the doctor.*" So they are laid out, registered, and their persons exposed and examined with the speculum, after which delicate operation they are told to come again in a few days for a repetition of the process. *This* is called with grim irony "the voluntary submission!"

Dr. Barr, of Aldershot, being asked respecting some women that the police had been "searching" for, as to what class of life they belonged to, replied,—"Dressmakers, married women, the wives of labourers and small tradesmen, and domestic servants *of course.*" Further, he is asked about the village of Frimley, near Sandhurst, and replies—"Occasionally I get a labourer's wife." Mr. Parson's being asked how it was that modest women submitted, replied—"Why, if they go to the Magistrate's Court it is known all over the town, and the husband and friends become acquainted with it." Fancy, a common prostitute with husband and friends ignorant of her mode of life! Again, Mr. Parsons is asked—"Have you had many cases of virtuous women brought up by the police?" He replies—"No, not many." "Have you had half-a-dozen such cases?" Observe the cautious reply—"I should think less than that." The Act had not been in operation quite five months when he was examined. He continues—"The Committee are aware that women have the power of appeal, but of that they will not avail themselves, because if they are obliged to go into court it is at once known to their friends. Consequently, he says, they prefer to come to me for a periodical examination, rather than go before a bench of magistrates, although either alternative is a very *painful* one. Out of many thousands that I have examined, there were not above three or four orders from a magistrate." Dr. Brewer asks—"Has any woman been brought by false acusations?" Mr. Parson replies—"Yes," and goes on to say, "One or two women have offered to take their oaths that they were modest women, and nobody has any power to release them but the magistrate, to whom they are unwilling to go." The chairman says—"Were they brought up by the police?" Answer—"*They were ! !*" The examiner continues—"So, then *modest* women submit for fear of being taken before the magistrates?" Answer—"*Ungestionably ! !*" Further, we read of a virgin denounced out of spite, and discovered to be such on examination; and of children brought up by the police, crying so like babies that the humane examiner sends for their mothers (who cry too) before—before what? Why before he introspects the children's genital organs. Mr. Percy Wyndham asks—"What course is taken with reference to girls, milliners, dressmakers, and others, who are at work all day, and who supplement (*i.e.*, are supposed to supplement) their earnings by prostitution?" The answer is—"They are classed as common prostitutes for the purposes of the Act!" Further, Mr. Parsons in reply to Dr. Brewer, says—"If you confine the Act to women, who are prostitutes—*i.e.*, who get their living by it, it would not be of the slightest use." Again, in reply to Mr. Tipping, he remarks, that—"Before the Act came into operation the Government applied to the Metropolitan Police to supply them with some statistics as to the number of women. They went through all those large towns, Portsmouth, Plymouth, Devonport, and so on, and found out from the brothel-keepers, publicans, and others, the number of women gaining a livelihood by prostitution. I know very well (he adds) that *now that number is doubled*, and I believe the increase has arisen from the discovery of persons who are *attempting clandestine* prostitution, whatever that may mean, because the openly avowed common prostitute is as well known as any one else." What is Mr. Berkeley Hill's oft repeated and widely circulated assertion, that the law only applies to "notoriously vicious women—women who *seduce* for gain," worth in the face of evidence such as this? In fact, the law makes women prostitutes by enforced registration, who never were and

never would have been but for its cruel and unjust provisions. Thus, it is evident that this law is applied to the utter debasement of a class of women who are merely *suspected* of incontinence by policemen; and if I am told that there is no class among men analogous to the women who trade in their person, I reply that there are plenty suspected of incontinence, who seduce, debauch, and disease women, and who are just counterparts of the poor girls who are herded like cattle and periodically violated at the present moment in our garrison towns, in order that such men may be vicious with impunity—not that I would defend the application of the law to men, because I look upon the whole thing, applied to either sex, as both a crime and a blunder. So much for the social effects of a law which is clearly unjust in principle, obscene in practice, and, in my opinion, demoralizing to all concerned. It remains now to consider how far it is defensible on purely sanitary grounds, and in briefly considering this portion of my subject, I shall first deny *in toto* that there is any necessity for exceptional legislation on the subject of contagious venereal diseases. The unanimous testimony of all surgeons, both civil and military, goes to show, that these diseases have for the last two centuries been declining both in extent and virulence, both in the army and out of it, until we can scarcely recognise them as the maladies described by our forefathers. Dr. Balfour, head of the statistical branch of the Medical Board, says, "It may be stated generally, that prior to the introduction of the Act there had been a progressive decrease at all the military stations in the amount of this class of diseases," and I find from a reference to the same gentleman's tables given in the appendix to the evidence of Lords and Common's Committees, that venereal diseases were falling off in the following proportion among the soldiers and sailors prior to the adoption of this measure. At Devonport and Plymouth there was a reduction of 151 cases per 1,000; at Chatham and Sheerness of 59; at Thorncliffe of 108; at Woolwich of 269; at Aldershot of 106; at Portsmouth of 174 per 1,000, without any interference whatever. Surgeon-Major Wyatt of the Coldstreams, speaking before the Act had passed, says—"We never see now the ravages formerly committed on the appearance and aspect of the men. The cases we see are of an exceedingly mild type." Mr. Byrne, of the Dublin Lock Hospital, states—"There is not nearly so much syphilis as there used to be; formerly, we used to see daily in the streets persons who had lost their noses from syphilis; now, you will not see such a case for years." Mr. Syme says—"None of the serious effects formerly derived from syphilis ever appear, and even the trivial ones comparatively seldom present themselves;" and Mr. Simon remarks that—"Even the worst form of venereal affection, true syphilis, is not in an *enormous* majority of cases of more than transient importance to the persons attacked." The best authorities state that prostitutes who suffer most from such affections are as a rule rather healthier and longer lived than married women or female operatives, who lead orderly lives; and English soldiers and sailors who are said to suffer to an almost equal extent are certainly the finest body of men in the world. Dr. Druitt said that—"The cases of syphilis seen in London in the present day, are unimportant and soon got over." And out of twenty of the leading practitioners in the Metropolis, eighteen declared that they did not meet with the after effects of that disease in the cases coming under their care. Many surgeons who have been in practice from twenty to forty years have assured me that they have never seen a severe case of syphilis in the whole time; and the editor of the *British Medical Journal*, in a recent article, remarked that even taking the notched teeth and other signs attributed to inherited syphilis, they certainly did not occur in one of 5,000 of our population. I need not dwell on these facts. No one denies them. And it is an unquestionable fact, that there is less necessity for legislation now than there ever has been any time during the last two centuries.

We are told by the Association for extending this Act to the whole of the women of this country, that the venereal disease (mark the term!) is a disease of the gravest character, constantly transmitted from parent to offspring. Now, about fourteen-fifteenths of these cases are entirely local affections—gonorrhœa and non-infecting sores of no consequence, either to the patients themselves or any body else—certainly not diseases of grave character; and there is no disease whatever of venereal origin that is constantly transmitted from parent to offspring. Only one case in fourteen or fifteen, where the constitution becomes affected, is truly syphilitic, and this is the only affection which can be considered a matter of State concern. Yet, M. Fournier tells us that if this worst form is judiciously treated, not more than five persons in 100 affected would be seriously injured. In fact, we all know that the vast majority of cases, even of true syphilis, are readily and permanently cured, never afterwards troubling the patient, or affecting his offspring; and it is a fact that, the milder affections, gonorrhœa and soft sores, though unimportant of themselves are still great checks upon incontinence, and consequently the means of saving thousands from the more serious malady. I shall next deny, Sir, that the means proposed would suffice to attain the object in view, and I do so on the following grounds:—First, in face of the most satisfactory decline, prior to legislation, as indicated in the tables already quoted, I find since the adoption of the Act up to the latest published reports, to the end of 1868, that there has been at the same six stations Devonport and Plymouth, Chatham and Sheerness, Shorncliffe, Woolwich, Aldershot, Portsmouth, a slight diminution at three, a large increase at one, and a decided increase at two, showing an aggregate increase of sixty-six per 6,000 of force under the Act, in face of a decline prior to the Act of 871 for the same number. Taking Devonport and Portsmouth, the stations where the most satisfactory results are said to have been obtained, the number of cases per 2,000 was in 1860, 943; in 1864 it was 626; a diminution of 317 without any act. In 1868 it was 629, an increase of two after four years' trial of the system under most favourable conditions. In the same way if we take the three stations last brought under the Acts, Shorncliffe, Woolwich, and Aldershot, the number at these three stations combined in 1860 was 1,139 per 3,000; in 1866 it was 671, a reduction of 468 without any Act. In 1868, it was 725, an increase of 54 in two years under the regulation system. We get similar evidence from abroad. Dr. Huet, first physician to the Hospital at Amsterdam, has published an elaborate report on prostitution, and the effects of the regulation system. On disease in the army, he takes several cities, and compares the amount of disease in the aggregate among the men, several years before the adoption of periodical examinations of prostitutes and several years after its adoption. Nothing can be more conclusive than its results. Before the introduction of ordinances 1,786 cases amongst 15,913 soldiers yearly, after the introduction 2,241 cases in 16,810—*i.e.*, 11·2 per cent. before, and 13·3 per cent. after. An exactly similar sequence of events has been noticed in the presidency of Bengal. Before the adoption of the Act the number of admissions per 1,000 was 166; but in 1868 the number rose to 199 under the operation of the law. The last report as to the sanitary condition of Bombay affords similar evidence as to inefficiency, but I cannot quote further. Why should such regulations fail in the attainment of the object in view? The reason is plain. The periodical examination of prostitutes affords a false security. They make vice apparently safe and increase its prevalence, but they are in reality as futile as they are filthy. Mr. Evans who had an excellent opportunity for studying the French system, and its effects upon our Army of Occupation at Valenciennes says—"it is abundantly evident that the condition which communicates disease in the female, is only to be known by its effects; and it is thus, that Government regulations for checking disease so entirely fail in the attainment of the

object in view." This observation is especially true of syphilis, the only disease we are interested in checking. Thus, I find from Ch. Puche and Fournier's table, that of 873 men under their care for syphilis, 625 contracted the disease (believing themselves safe) from registered and regularly inspected women. Dr. Vintras says, that at least *two-thirds of the cases* of true syphilis in Paris are derived from inspected women. Mr. Simon, who is acknowledged to be one of the first pathologists in Europe, says—"the various local states which most habitually spread the infection of true syphilis, are constantly overlooked in examinations made expressely for their discovery." Dr. Aitken in his well known work on the "Science of Medicine," says—"Medical inspections are formal and look useful; but the infecting sore, the true syphilitic one can rarely be detected in the female." In another part of his work he observes, "the syphilitic sore, when it does occur in women, is readily overlooked, even when searched for with great care aided by a vaginal examination with the speculum." Dr. Macloughlin during twenty-seven years' practice in Paris, made a point, whenever practicable, of examining the women from whom his patients had contracted syphilis, and he says it was extremely rare to discover the source of infection in the female, and Mr. Skey, writing to Dr. Macloughlin and referring to these facts, says, —"I am convinced in common with many surgeons, that every form of sore, and every variety of discharge, from the slightest to the severest in intensity, are obtained from women who have not discoverable indications of disease of any kind." I could quote pages of similar testimony. Do not these facts totally uproot the very groundwork of the Acts? If it is alleged that, in spite of difficulties of diagnosis the worst cases may be detected, then I say syphilis is the only disease of consequence, and it is precisely the disease you can so rarely discover in the female. Besides, the working of the Act has proved that the worst cases are most eager to apply voluntarily to hospitals for cure. In fact, to use Lord Lennox's expression (who fancied he was defending compulsion when proving it was not needed), "they flock to the hospitals." Lefort says—"what with infection derived from inspected women, and the effect of the system in multiplying clandestine prostitutes, the means employed against syphilis in Paris amount to nothing." Like most Frenchmen, he has a remedy absolutely indispensable to success. Here it is: 40,000 clandestine prostitutes must be forced on the register; children under age must be registered in spite of their parents; the whole must be compelled to live in brothels for greater convenience of inspection. Moreover, Lancereaux and all other authorities state, that the examinations must be multiplied. Once a week is absurd. They should take place *at least every other day*, and the women must be shut up several hours before they are inspected and carefully watched, so that they may not wipe away discharges or use syringes. Then they must be examined and the mouth, the throat, the stripped skin, carefully inspected, and the genital organs introspected. Surely, that is enough? The woman may go now? No, Sir! Lancereaux says (and I can quote no higher nor more modern authority), "it is *absolutely indispensible to carefully introspect the anus with a speculum*, and to keep women prisoners after recovery who have had sores, lest secondary symptoms should crop up in course of time!" All authorities are agreed that after all the slightest possible security is ever obtained, and the head of the Parisian Police, Commissionaire interrogateur, and Chef de Bureau de Mœurs, solemnly warns us that to obtain any good at all we must inspect as frequently and carefully as the authorities I have just quoted have proposed. Nothing less will do. He mournfully adds that—"all the results prove that prostitution is increasing in Paris, and that it is more dangerous than ever to the public health. The evil is a moral and social one, and cannot be controlled by the police, nor by legislative measures." In a letter to Mrs. Butler, the same authority says—"by science we have increased and not diminished the evil." There are at the present moment in Paris, in spite of the efforts of the police, 9,500 patients under treatment in hospitals for venereal diseases, and 47,500 cases at the very lowest computation in a city, the population of which is one half that of London (*i.e.*, a million and-a-half), while among a poor population of a million and a-half in London we find from Mr. Wagstaff's careful investigations, and the report of the Medical Officer of the Privy Council, there are only 455 cases of syphilis. In fact, the system by giving a false security, offers a direct inducement to thousands, especially married men, to contract disease. The examinations fail also because healthy women by mediate contagion communicate infection; because owing to the menstrual period they cannot be carried out in a large number of cases, (thirty in one day at one station have not been examined on this account); because also it is impossible to distinguish gonorrhœa from leucorrhœa. Again, women are exposed to great danger of infection from contaminated instruments. In a short space of time seventeen cases of communication by the Eustachian catheter were recorded in Paris, and if we do not hear more of its transmission by the vaginal speculum, it is simply owing to the seat of the evil. The examinations fail, too, because the inspection and restriction of one sex only for a disease common to, and propagated by both sexes, is not only a cruel injustice but is a delusion and a snare; and they also fail because the system calls into existence and fosters a numerous class of clandestine prostitutes who, from fear of detection, conceal their disease and become permanent sources of infection. Now, Sir, we have been accused of wishing to see people go on suffering from venereal diseases. We do not. We believe that such laws increase the evil, and that is one reason why we oppose them. We know also that other means entirely unobjectionable, christian and merciful would suffice. The advocates of the Act constantly point to their hospitals as though the hospitals were the essence of their system. We don't object to hospitals. We object to spies, and periodical examinations of healthy women; which is the real essence of their system, and all we stipulate for with regard to hospitals is, that the doors shall be open by christian charity, and not by the police. Mr. J. R. Lane says—"much more good may be done by free hospitals than by police interference. Police regulations can get only a certain number of women, whereas free hospitals would attract all suffering from disease, even those who contracted it clandestinely and who would escape the police." If time permitted I could quote a mass of evidence to show that women who are diseased will go anywhere to be cured, and everything beyond the establishment of hospitals is as unnecessary as it is inexpedient and utterly opposed to the free spirit of all English institutions.

It would be well, Sir, if the advocates of this law would limit themselves to the possible everywhere at home and abroad. Such unjust statutes are regarded with aversion, and are directly and bitterly opposed to the feelings of the inhabitants. In Great Britain the voice of the country is loudly raised against them. Eight hundred petitions, signed by half-a-million of people, and representing in the shape of one chairman for large public meetings many more have already been presented against them. It would be impossible to defend the Acts at any public meeting, and if you tell me that the health of the people is the supreme law, I shall reply, "*Vox populi, vox Dei.*" I want the medical profession to be rid of the discredit of this legislation. Mr. Holmes Coote tells us that the few earnest men, among whom he was a principal worker, and who met to discuss means of giving shelter to sick prostitutes, "*would have scouted*" this miserable abortion of a law which, he adds, "would disgrace a despotic monarchy." George Thomson the well-known anti-slavery orator, remarked at a recent meeting in this town, that, "these Acts exceed the constitutional power of Parliament." He says:—"They have sanctioned a measure which is at once immoral, indecent, and revolting, and a most atrocious invasion of the sacred and, as I believe, in-

defeasible personal rights belonging to every woman, even the most degraded and most outcast." Professor Newman remarked at a recent meeting in London—"the state maxim of the wisest of the Greeks was this ; an injustice to the meanest citizen is an insult to the whole community." Grant that women who trade in their persons are the meanest of citizens, they do not cease to be citizens, much less to be women. It is not only becoming in us, it is our absolute duty to be indignant, and loudly to declare our indignation at the indecent, depraving, and barbarous treatment to which fallen women are now subjected, as well as at the overthrow of legal safeguards for all women. When bodily instrumental outrage is inflicted on females, no man with a heart in him will speak of it softly. Women, nay, wives and women who recently have been or are about to be mothers ? Such violation of the person is an intrinsic wickedness, an indefeasible atrocity. Legislation is desecrated; parliament is dishonoured ; resistance becomes nature's own command when such things are enacted.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XI.

TREATMENT OF SEWAGE BY CHEMICAL PROCESSES.

THE offensiveness of sewage and cesspool matters, as well as the more or less exaggerated estimate of their agricultural value, have served at all times as a powerful inducement for the discovery and application of some simple process whereby the most important constituents of these matters might be so disinfected and consolidated as to render them not only inoffensive to the public, but also useful to agriculture and fit for commercial purposes. Chemists of great celebrity, as well as the merest dabblers in experimental science, have devoted attention to the subject, and have proposed the use of all kinds of materials for the purpose in question. A glance, indeed, at the following table, which exhibits most of the suggestions for the treatment of these matters over a period of nearly a hundred years, will show how completely the subject has been explored, and how futile have been the results. Almost every description of waste product, as well as many rarer chemical compounds, have been vainly resorted to, and made the objects of unprofitable patent inventions. The caustic alkalies, mineral acids, metallic salts, empyreumatic oils, spent tan, vegetable charcoal, trade and household refuse, and all sorts of worthless substances have been successively and often repeatedly used for this purpose.

Name of substances.	Inventor.	Date
Acetate of lead and protosulphate of iron	Deboissieu.	1762
Chlorine	Hallé.	1785
Quick lime.	Estienne.	1802
Powdered charcoal	Giraud.	1805
Chlorine and chloride of lime	Guyton Morveau.	1805
Ashes	Chaumette.	1815
Sand	Duprat.	1818
Sulphate of iron	Briant.	1824
Chloride of soda	Labarraque.	1824
Waste chloride of manganese	Payen and Chevalier.	1825
Sulphate of lime	Siret.	1827
Animal charcoal	Frigerio.	1829
Peat	Guibourt & Sanson.	1833
Charcoal and calcined marl or river mud	Pottevin.	1835
Sulphates of iron and zinc with tan and tar	Siret.	1837
Earth, lime, and waste substances	Rossier.	1837
Peat ashes	D'Arcet.	1840
Metallic oxides and carbon.	Krafft & Suequet.	1840
Chloride of zinc	Sir Wm. Burnett.	1840
Schist coke	Hompesch.	1841
Trade refuse, charcoal, and ashes	Albert.	1842
Powdered lignite	Jourdan.	1843
Impure alum	Siret.	1843
Sulphate of zinc, charcoal, and clay	Gagnage & Regnault.	1844
Persulphate of iron	Baronnet.	1845
Schist coke	Du Boisson.	1845
Chlorides of iron and zinc	Dubois.	1846
Lime and precipitating tanks	Higgs.	1846
Nitrate of lead	Ledoyen.	1847
Waste salts of iron, lead, zinc, &c., with pyroligmatters, ashes, &c.	Brown.	1847
Pyrolignate and perchloride of iron	Ellerman.	1847
Impure chloride of manganese	Young.	1847
Dried sea-weed, lime, and sulphate of lime and zinc	Salman.	1848
Peat charcoal	Rogers.	1848
Charcoal, soot, mineral salts, &c.	Legras.	1849
Spent tan, carbonised	Tarling.	1850
Fresh bark, sulphate of iron, and peat charcoal	Angely.	1850
Metallic sub salts, as of iron, alumina, &c.	Browne.	1850
Milk of lime and collecting the deposit	Wicksteed.	1851
Acids and metallic salts, and filtrations through charcoal, clay, peat, gypsum, &c.	Dover.	1851
Lime, sulphates of alumina, and zinc and charcoal	Stothert.	1852
Lime, magnesian earth, sulphate of zinc or iron and vegetable charcoal	Gilbee.	1852
Sifted ashes, breese, or peat charcoal	Perks.	1852
Sulphate of zinc, potash, alum, and sand, with waste tan, ashes, lime, soot, &c.	Pinel.	1853
Metallic sulphates, metallic chlorides, or charcoal and magnesian salts	Herapath.	1853
Salts produced in working galvanic batteries	Dering.	1853
Peat or bog earth containing salts or oxides of iron	Dimsdale.	1853
Peat and other charcoal and chloride of sodium, &c.	Macpherson.	1853
Animal charcoal, alum, carbonate of soda and gypsum	Manning.	1853
Magnesia and lime with sulphurous and carbolic acids	Smith & McDougall.	1854
Lime and finely-divided charcoal	Wicksteed.	1854
Boghead coke	Herapath.	1854
Soft sludge from alum works with lime and charcoal	Manning.	1854
Peat charcoal carbonised with oil of vitriol	Longmaid.	1855
Alum schist or shale, and other aluminous minerals, with lime and charcoal	Manning.	1855
Manganates and permanganates	Condy.	1857
Superphosphate of lime with magnesia and lime	Blyth.	1858

Hardly anything can be more illustrative of the reckless way in which inventors endeavour to apply their knowledge, without first ascertaining what has been already done in the matter, and how far it has been found successful. Quicklime, for example, as well as the various forms of charcoal, and the salts of iron and alumina, have again and again been the subjects of patent invention. But, besides this, there have been many patents for the most elaborate treatment of sewage and nightsoil. White, in 1854, proposed to carbonise nightsoil in a close retort, and to mix the products with dried blood, dried nightsoil, superphosphate of lime, wood ashes, &c., and so to form them into a manure. Bardwell, in 1853, and Littleton and Anderson, in 1854, proposed to utilise the ammonia of sewage by processes of evaporation and subsequent absorption; and Noone, in 1865, actually distilled the sewage, and obtained a liquor which was charged to the extent of 38·75 grains of ammonia per gallon; but, as in practice it required about 1,000 gallons of sewage to furnish this quantity of liquor, the value of which was only about five farthings, the process was soon abandoned, although it was most hopefully entertained by the authorities of Hastings, where it was fully tested on the sewage of the town. Patents have also been taken out for the speedy desiccation of the solid matters precipitated from sewage, as by Perks in 1852, Needham in 1853, Wicksteed in 1854, Kite in 1854, Noone in 1864, &c.

In connection with this subject, it may not be out of place to refer to the experiments of the late Dr. Davy on the deodorising power of different substances on nightsoil. He took 125 grains of nightsoil, and found that the following were the proportions of the several substances required to deodorise it:—Volatile oils, including naphtha, gas tar, and creasote, from one to two grains; fixed oils, from four to thirteen grains; a mixture of vinegar and creasote, one grain; vinegar alone, eight grains; pyroligneous acid and nitro-muriatic acid, four grains; chromic acid mixed with strong sulphuric acid, eight grains; sulphuric acid alone, twenty-two grains; a saturated solution of euchlorine, forty-one grains; ditto of chlorine, ninety-four grains; ditto of chloride of lime, forty-seven grains; but sulphate of iron, chloride of zinc, muriatic acid, and bichromate of potash had little or no deodorising power.

The following are the results of experiments made by Dr. Letheby in the year 1858, when he reported to the City authorities on the subject of sewage and sewer gases.

Quantities of different disinfectants required to deodorise ordinary London sewage.

Deodoriser.	Price.	Grs. required per gallon of Sewage.	Results as to Deodorisation.	Cost per 100,000 gals. of Sewage. £ s. d.
Quicklime - -	10s. per ton.	12	Incomplete.	0 0 9
Chloride of Lime -	£15 ,,	8	Complete.	0 15 4
McDougall's Powder	£12 ,,	40	Incomplete.	3 1 3
Peat Charcoal - -	£3 5s. ,,	150	Ditto.	3 2 3
Condy's Liquid -	1s. per gal.	150	Complete.	10 14 4
Dale's do, - -	6d. ,,	313	Incomplete.	11 3 7
Ledoyen's do. - -	4d. ,,	1,000	Ditto.	23 16 4
Ellerman's do. -	9d. ,,	470	Ditto.	25 3 6
Sir W. Burnett's do.	4s. ,,	100	Ditto.	28 12 0

The several liquids used in these experiments had the following strength:—

	Sp. Grs	Grs per gal	Of following.
Condy's Liquid	1,055	4,357	Permanganate of Potash,
Dale's do.	1,470	64,827	Perchloride of Iron.
Ledoyen's do.	1,160	8,120	Nitrate of Lead.
Ellerman's do.	1,443	43,434	Muriate and Pyrolignate of Iron.
Sir William Burnett's do.	1,594	60,031	Chloride of Zinc.

In those cases where the deodorisation was incomplete, the peculiar smell of sewage remained—sulphuretted hydrogen, and, except in the case of quick-lime, ammonia being the only volatile matter removed. In all cases the substances were added until subsequent decomposition was entirely prevented.

The thick matters of cesspools, and of stagnant sewers required about a twentieth part of their weight of chloride of lime to deodorise them, and the corresponding proportions of the other deodorisers.

We will now examine the practical results of the various disinfecting and defæcating processes on a large scale, as at the several sewage works where they have been used.

Transactions of Societies.

THE MEDICAL SOCIETY OF LONDON.

October 31st, 1870.

DISCUSSION ON THE MEDICAL ASPECT OF THE GERM THEORY.

To facilitate the discussion on the paper read by Dr. Richardson on the 24th inst., the President read a short abstract of the author's views on the subject of "The Medical Aspect of the Germ Theory." Two theories had been set forth—viz., The Vital or Germ Theory, and the Physical Theory of the Communication of Disease. Certain truths are common to both these theories and are generally accepted; these are, 1st. That certain diseases arise from organic poisons; 2nd. That such poisons are solid, probably colloidal in nature; 3rd. They are transmissible from person to person, and transmitted and capable of exciting disease; 4th. The poisons are specific for each specific disease. Dr. Richardson objects to the germ theory on the grounds that, 1st. The presence of the assumed germs is not proved; they are not found as definite parts of the different poisons; 2nd. The specific character of each germ is not traceable in such specific malady; but is assumed on the ground that the diseases being themselves specific must therefore proceed from specific causes; 3rd. If the germs are reproductive and indestructible the universe would become filled with germs, which, as media of disease, would destroy the people. Neither fermentation nor putrefaction can be proved in any forms of disorder to which the germ theory is applied. The germs being entities we are led to regard diseases as entities—manifestly a retrogade step in science. The germ theory neither explains nor tallies with what we know of the progress of these diseases. The second part of the paper deals with the physical as opposed to the germ theory. Dr. Richardson believes in organic poisons as the causes of communicable diseases; these poisons may become solid, but they are not reproductive, independent germs, they are not derived from without, nor are they produced out of the body. They result from morbid changes within the body, in the secretions. These poisonous secretions convey disease from one body to another; the perspiration of the hand possessed with poison of puerperal fever may become a means of conveying the disease to an infinite number of patients as in a case known to Dr. Richardson. The reproduction of the introduced poison is charged to the reproduction of the secretion affected by the poison, as the skin surface in scarlet fever, and the bile in yellow fever. The poison may be destroyed, and then the disease caused by it dies out. Of this we have numerous instances in diseases now extinct among us. The physical theory explains the nervous derangements as then follow a disturbance or irritation of secretory surfaces. It explains how a communicable disease may be purely local in its action, and how, beginning locally, the disease may spread generally. There may, perhaps, be a process of zymosis continually going on in the body, but this would be diminished rather than increased during the action of the poison.

Mr. De Meric did not consider gonorrhœa had a place among the diseases communicable by specific poison, it was an inflammation only. With regard to syphilis, the case was different, but we were quite in the dark as to the nature of syphilitic virus. With respect to the colloidal nature of these poisons, Mr. De Meric mentioned experiments by Chauveau, of Lyons,

who had shown that when globule and cellular matters were eliminated the clear serum yet retained poisonous powers.

Dr. Sansom referred to a previous paper he had read before the Society. He believed the theory set forth by Dr. Richardson to be absolutely and entirely erroneous. Vital molecules were essential to fermentation and putrefaction. Infectious diseases were due to vitalised molecules; Chauveau had proved this. Dr. Sansom did not hold with the specific germ theory put forth by Haller.

Mr. Brudenell Carter said that it had been clearly shown by Professor Tyndall that the best test of the soundness of a theory was its fitting perfectly the facts to which it was applied. A most communicable disease was found in the contagion of ophthalmia introduced into France into 1779 and 1830—a cause of total blindness in 4,000 soldiers in Belgium. This disease had now been shown to be due to sago-like grains deposited on the eyelids, connected with obstructed lymphatics in the connective tissue; these, when they become inflamed, produced the ophthalmia. Here, then, was a very contagious disease, but no evidence of the presence of germs as a means of communicability.

Dr. Bindon Sanderson agreed with Dr. Richardson in the main points, certain contagious matters seemed to consist of colloidal matter. Further experiments were essential to solve the question involved.

Dr. Schulhof thought the communicability of coryza and the destruction of contagious matter by disinfectants were rather in favour of the germ theory.

Dr. Crisp mentioned his own researches on the splenic apoplexy of animals. Davaine, in France, thinking this fatal disorder depended on bacteridies, inoculated rabbits with the blood of creatures that had died of splenic apoplexy, and they were all poisoned and died. Vegetable parasitic diseases lend support to the germ theory in their spread, which might be more fully explained at a future day. Living germs might become extinct just as some creatures—the dodo and the Great Auk had become extinct.

Mr. Brooke said that if we adopt the germ theory, we must admit azonic or spontaneous generation, or ignore the sporadic origin of zymotic diseases, an essential difficulty.

Dr. Temple recognised a great distinction between fermentation and putrefaction; the one led to the formation of permanent and stable products, such as alcohol, the other quite the reverse. Electrical stasis of the atmosphere were not sufficiently regarded as influencing diseases.

Dr. Routh thought that in hay-fever we had an example of a disease caused by vegetable germs. Sporules, or germs, might be seen also in substances scraped from infected surfaces.

Dr. Wolff spoke of the similarity in the action of contagions,—might then be an universal agent whose action was modified by local surfaces?

Dr. Silver showed how Lister had made his belief in the germ theory of practicability, by excluding germs from wounds; by means of carbolic dressings pyæmia was prevented, and rapid healing promoted; colloidal particles might show evidence of life in the presence of microzomes.

Mr. Jabez Hogg concurred with Dr. Richardson in his views. In respect to fermentation, Mr. Hogg had found that this might be set up without the aid of yeast in a saccharine solution, and much alcohol be formed.

The President then asked how the accepted doctrine of the spread of cholera could be explained on the physical theory?

Dr. Richardson, in reply, said that he did not profess to explain what the exact changes were that took place in a secretion to render it poisonous. To the President's question, he said that in cholera a specific product or poison was generated, the smallest portion of which taken in by another, poisoned the alimentary canal of that person. There was no reproduction of the thing itself. In reply to Dr. Sansom, Dr. Richardson said there was no evidence to be found of fermentative process in any disease, save increase of temperature, and this was not essential. He said that his namesake, Dr. Richardson, of America, had inoculated himself with bacteridies without any actual result being perceived. Mr. Wolff's theory would render all so simple that Dr. Richardson would be glad to find it prove true. Noxious gases had nothing at all to do with the production of communicable diseases, and the success of some surgeons, who never used or heard of carbolic acid, was equal, or superior to that of those who used it in the most approved and careful way. The physical theory would account for the spread of all communicable diseases.

"SALUS POPULI SUPREMA LEX."

WSEDENDAY, NOVEMBER 9, 1870.

THE CONTAGIOUS DISEASES ACTS AT COLCHESTER.

The opponents of the Contagious Diseases Acts, seem to be as determined as ever in their opposition to the new state of affairs in our garrison towns. A split in the liberal party seems to have taken place on the question at Colchester, where Sir H. Storks, after having lost his election at Newark on account of his complicity in the passing of these Acts, has again been defeated. Friends of the Acts say that they are working admirably, and that, in every military and naval station where they are in operation, the health of the troops has been greatly improved, whilst, at the same time, the health of the prostitutes of the localities has gained immensely, and that there is far less open solicitation to be remarked than formerly in all those localities. They are all therefore anxious to extend the operation of these laws to every city in this empire, both at home and abroad, whether soldiers or sailors are found in such places or not. Evidence is so conflicting; the advocates on both sides so eager, and party spirit runs so high, that it is difficult for anyone who desires to write impartially on the subject, as all editors, of course, ought to endeavour to do, to see the way clearly to any definite conclusion.

Such being the case, it would perhaps, be better to have up a few more witnesses before we definitely conclude for either plaintiff or defendant. Now, in a recent meeting at Newcastle-on-Tyne, in September, Mr. Duncan McLaren, M.P. for Edinburgh, gave some evidence against the Acts, which does not as yet seem to have come before the notice of the medical profession, and which, therefore, it may not prove uninteresting for us to reproduce. Mr. Mc'Laren says, that the Contagious Diseases Acts, came into operation in 1865, in Portsmouth, Devonport, Sheerness, and Chatham, and in 1866 in Woolwich, in 1867 in Aldershot, in 1868 in Windsor, and Shorncliffe, in 1869 in Colchester. All the women of the class defined, were enumerated and registered at the commencement of the Act, and the names of all "new comers" into each district added to the register, and also those who left. A

return of the results of the Acts was moved for in the House of Commons before the prorogation : but not issued till long after the House rose. This return is in two parts. The chief part consists of statistical tables, respecting each district. The second is a report, professing to condense the evidence derivable from the tables. Mr. McLaren considers the latter to be a deceptive production, and not creditable to the Admiralty Department, by whose authority it was issued. "Firstly" it is stated in the first page, "that 7,766 women were on the register, and that this number has now been reduced to 3,016." "I shall prove from the tables that, as compared with the numbers at the commencement of the Act, no diminution whatever has taken place in the number of these women resident within the districts; but on the contrary, that there is an increased number of these women now residing within them," says Mr. McLaren. It has also been said by a supporter of the Acts in the report "I am desirous of calling particular attention to the effect produced in Plymouth. There has been, from year to year, at this station, a steady and increasing diminution in the number of brothels, as likewise of prostitutes attending the same, which decreased from 1,770 to 645." Mr. McLaren says, that the tables show that this is a falsehood. The report states too, that in the case of 300 women, who left Plymouth at the commencement of the operations of the Act, "their places are not filled by new comers." This again, Mr. McLaren says is quite false. The report likewise says, that, "the decrease in disease is likewise remarkable. I may mention Chatham : the disease in 1863 was 70 per cent. ; in 1869, 18 per cent. ; in 1870, 6 per cent." Mr. McLaren is prepared to prove that disease has greatly increased. And he gives the following reason. Firstly, with respect to the alleged diminution in the number of prostitutes from 7,760 to 3,016, he tells us that in one of the tables in the report, the registered number of prostitutes when the Act came into operation is given. Now it appears from this, that, in the stations of Portsmouth, Devonport, Sheerness, Chatham, Woolwich, and Aldershot, when the Act came into operation, there were a total of 1,244 prostitutes : and the number remaining on the register on the 26th March, 1870, was no less than 2,236, a great increase instead of a decrease, as alleged. The fraudulent figure 7,766 given, as having existed in these towns at one epoch, includes all the women who have been on the regular for several years. It was on such statistics as these, that some of the enthusiatic medical supporters of the Act relied on their recent attempts to press the extension of the Acts on the House of Commons.

The next allegation was that in Plymouth or the Devonport district the number of prostitutes has "been reduced from year to year, till from 1,770 they have become only 645, and that the places of those who left were not supplied by new comers." Mr. McLaren says the facts are these—In place of 1,770, there were only 203 prostitutes when the Act came into operation in 1865, and in place of the "steady and increasing diminution" alleged to have taken place, the numbers in 1868 had increased to 390. In place of no "new comers" being added, there were, according to the tables, during 1866, no fewer than 333 added, and 179 of these formerly registered had left or died. With respect to the alleged diminution in the amount of disease, Mr. McLaren observes that, if we turn to the tables, we find for Chatham that, beginning with 1866, the number of cases sent to the Lock Hospital was 277 ; in 1867 it was 463 ; in 1868 it was 686 ; and in 1869 it was 697 ; and yet the number of women resident was nearly equal during each year. It is to be particularly noticed, says Mr. McLaren, that in nearly every town and district there is an increase in the amount of disease in 1869 over 1868. Women were actually examined 49,389 times, and found free from disease ; 14,268 examinations had a different result. The report was ordered by the House of Commons, and was furnished on Government responsibility ; and Mr. McLaren observes at Newcastle that, although he had possessed rather a ravenous appetite for blue books and other statistical documents, and had, in various ways, dissected not a few of them, he felt bound to say that this was the most unfair and untruthful public document it had ever been his lot to meet with.

And thus we leave, for the time, this knotty point with the remark that, if Mr. McLaren's statements are as correct as they seem to be, Mr. B. Hill and the Society for the Extension of the Acts will have a hard fight even to maintain the ground they have won. For, after all, unless the hygienic utility of the Acts were made out to be as evident as the summer sun at noon-tide in a cloudless sky, these Acts could not be long maintained in the modern deluge of men and women's-rights movement. The Franco-Prussian War, even, has damaged the chances of the maintenance or extension of the Acts, since, as Mr. Lowe observed in Scotland recently, it has rung out the knell of celibate standing armies. We shall be glad to know what statements can be made to sustain or invalidate those mad e by the M.P. for Edinburgh in September last.

Notes on Current Topics.

About the War and Wounded

On the 25th ult., the special correspondent of the *Times* with the Crown Prince's Army, visited the stores of the British Society for Help to the Sick and Wounded. Their depôt is at present in the coachhouse of a mansion in the Rue des Reservoirs, which is filled with bales of shirts, flannels, medical and physical comforts, which are distributed by Mr. Furley, who is assisted by Dr. Reichel and a few soldiers. All articles taken from the store are entered in a book, which is signed by the recipient, and the demands from Prince Pless, Prince Putbus, Prince of Tour and Taxis, and others are numerous for the service of the hospitals, the Bavarians especially being short of many necessaries. Indeed, the German hospital establishments do not at all come up to our ideas. The representative of each branch of the National Associations does the best he can for his own compatriots, for in Fatherland there are still a variety of children—the Prussian for the Prussians, the Hessian for the Hessians, the Bavarian for the Bavarians, the Wurtemberger for the Wurtembergers, and so on—each works for his own compatriots. Dr. Kirchner, who is an energetic person, rules his palace and his hospitals as the Lord of the Silver Bow lorded it over Tenedos. I am not going, says the correspondent, to put my finger into the hot water which the medical men are making in their kitchen, but it seems as if a strict rendering of the rules of the Geneva Convention were not compatible with the views of exclusive control entertained by the Prussian medical men.

***

We take some further extracts from his letter :—"I went round through the Palace wards afterwards, begin-

ning with those in charge of the Dutch ambulance, which is admirably conducted by Dr. Van der Velde, the Palestine traveller. As might be expected, these wards were exceedingly clean and neat. 'Wards,' indeed! The first I entered was the 'Salle des Guerriers Celèbres'—the ancient antechamber to the apartment of Madame de Pompadour—in which were the usual hospital scenes—a Sister of Charity with a bowl in one hand and a spoon in the other feeding a soldier too weak to rise; a surgeon dressing a dreadful wound: 'I'm trying to save the joint, but I fear—still, it's a neat case.' The poor wretch looked at the shattered bone as if he more than shared the doubt. Hospital orderlies moving about the rows of pale faces with anxious eyes, and above them all these brilliant warriors, in theatrical attitudes and glaring eyeballs, following you all over the place. It was an excellent idea of the Crown Prince. He suggested the changing of patients able to be moved from one room to another, so that the monotony of 'Hoche for ever,' 'Joubert as before,' and all the rest of them day after day, might not afflict the nerves of the sufferers and retard their cure. But, of course, it could not be carried out. On each door is a notice of the République Française, signed Jules Simon, relating to the internal arrangements of the hospital, and precautions against fire."

***

The same writer says about chloroform: "I wish Prussian surgeons used chloroform—that is, if it be desirable in a medical point of view. But it is not in favour with them, nor is it with the French. I see in the Paris papers specific directions for the treatment of wounds, in which chloroform is objected to as well as the use of perchlurure of iron.' While I was in one of the Salles des Maréchaux, a surgeon was probing a gunshot wound in the thigh of a man, who uttered such harrowing yells that the Sister of Charity—there is one in each room—turned and fled, a wounded man nearly burst into tears, and all in the ward were agitated except the surgeon and his assistants, one of whom tried to stop the outcry by putting one hand on the top of the 'patient's' head, and squeezing his mouth and chin with the other, till the doctor lost his patience and roared at the wretched sufferer to be quiet, applying a strong term at the same time. The yell died into a whimpering moan still more dreadful, and I retired. The doctor is a very clever man, I am told, and has his hospital in capital order. And *à propos* of him, let me notice what seems an illiberality on the part of the Prussians, as well as a folly. Jews may become regimental and staff surgeons, but the post of Ober-Stabsarzt, which may be considered equivalent to our Deputy Inspector-General of Hospitals, is closed against them. So if they are fit for it the State is deprived of the services of able men in places where they are most needed."

***

"I promised I would not dwell on hospital scenes, and I shall refrain from the description of the linked misery which extends along three sides, as you remember, of the centre in the *rez-de-chaussé*—fourteen rooms, with their arrays of painted warriors. But there are 'cases' enough, some 'very curious.' A peculiarity about curious cases, I observe, is, that the surgeon generally, if not invariably, says, 'He can't live very long.' And no wonder—'time was when brains were out that men would die.' Well if it were always so."

***

"One man was alive with a ball lodged in his brain; he had even been conscious. Another had the side of his skull clean carried off by a bit of shell; a third in a ward all by himself was—but no! It was too horrible. The man was in mania, and Mr. Furley (who was with me) and I hurried into the next ward, whence an orderly was sent to keep watch and ward over the 'case.'"

***

"The gallery of Louis XIII., of the Admirals of France, and so on all round, are filled with wounded men to the end till we come to the officers' rooms. My first glance was at the bed on the left as you enter. I had seen a gallant captain of Artillery lying there the last time I visited it, which was in company with Count von Gortz, of Schlitz, and had witnessed his reception of a little deputation from the men of his battery, who had come in from Plessis-Picquet to see how their officer was getting on. The bed was empty. I was quite relieved to hear from a Bavarian officer sitting up, with one leg left, that the artilleryman, who had only lost the greater part of one of his thighs, had been sent away to complete his cure at home. The suites upstairs in the palace, or Château as it is more generally styled, are occupied in the same way as those below. There is at least silence in the rooms, broken only by the whispers of Sisters of Charity, the voices of chaplains by the bedsides, and the rustling of newspapers, which are eagerly read by the wounded; but the rooms are draughty and cold, and as winter increases in harshness there will be difficulties in ventilating the wards."

***

The following extract from a letter dated Oct. 29, from Mr. H. W. Page, one of the assistant-surgeons to the International Field Hospital at Bingen-on-the-Rhine, appeared in the *Times* of the 31st ultimo:—

"Last night, amid a storm unparalleled for its violence, and such as I never shall forget, which rose as suddenly as it departed, after forty-five minutes' duration, the whole hospital was swept off the face of the earth. Never was such a scene—never such agony! If it was awful for wounded men, without shoes or stockings, with nothing but their blankets, which in a second were drenched, to turn out and be exposed to the elements, it was even worse for the sick. Imagine a typhoid fever patient, for whom it is almost fatal to move in bed, having to take up his bed and walk. The storm began at 8.15 p.m., and not till 1 this morning did we succeed in housing the unfortunate creatures in the operation room, in the porter's lodge, and in the hotel. The wonder is that they all lived through it. To-day, what a wreck! Nearly every roof is stripped, and the people declare they never remember such a storm. The rest I leave to your imagination."

The School Boards.

Among the names we have mentioned as candidates for seats on the School Boards in London districts are Dr. Lankester, Miss Garrett, and Dr. Edmonds. We sincerely hope that many of our professional brethren may obtain such posts. The knowledge of physiology is further back than any other kind of knowledge, and medical men and women alone are aware of the immense importance of the topics contained in the science of hygiene, public and private. Morality is but the art which teaches us to live and let others live a healthy existence.

Professor Cairnes on Philosophy in France.

A few weeks ago we endeavoured, in a leading article, to show how important the study of true philosophy was to nations and individuals. That Professor Cairnes is of like opinion we glean from an admirable lecture delivered by that distinguished gentleman (who is a native of Drogheda, and formerly Professor of Political Economy in Galway) at University College on the evening of November 1st. Mr. Cairnes, as many persons know, has had the distinguished honour of having been permitted to edit the last edition of Mr. J. S. Mill's work "On the Principles of Political Economy." Speaking, the other evening, of the causes of the present war in France, he justly, we think, attributed that horrible event to the

low state of the science of political economy in France, and to the exaggerated views entertained by so many of the working-classes as to the capabilities of communism. "It was the fear of socialism and communism," said the learned Professor, "which reconciled the mass of the proprietors and capitalists in France to the iron rule of a despotic government; and this again led to dreams of conquest and dissolution of manners." We have no hesitation in asserting that Mr. Cairnes is the ablest political economist Ireland has ever seen.

Warts and their Removal.

A CORRESPONDENT complimenting us upon some of our recent annotations gives us the particulars of his treatment of simple warts when there is nothing more than simple hypertrophy of the papillæ and skin. He tells us he is uniformly successful, even where the ordinary methods of treatment in use have signally failed, of curing warts by passing through their base a double piece of silk by means of a straight needle saturated with creosote, and tied on either side of the wart. The wart being doubly tied from centre to circumference a hole is made in the middle, and if the wart does not speedily fall off, some fresh creosote on charpie can be introduced. "This treatment," he concludes, "effectually removes the wart *and destroys the root*, so that there is never reproduction occurring on the site of the old wart, so usual after the common remedies had recourse to, I have employed the creosote silk ligatures for warts of the eyelids with uniform success, and none are so liable to return."

Vaccina-phobia.

THE following is too good to be ignored :—

"On Friday, at the Preston Police-court, the Rev. Thomas Doody, Primitive Methodist Minister, was charged by Mr. W. Pinder, on behalf of the Board of Guardians, with refusing to have a child vaccinated. Mr. Edelston, for the defendant, said he felt himself in duty bound to his child to set himself against the law, not in a perverse or defiant spirit, but because some years ago he had a very fine child vaccinated, after which symptoms of a painful nature made their appearance, and the child died; and a neighbour's child that had been vaccinated with the virus from his child, also died. Other facts of a similar kind had since come to Mr. Doody's knowledge, and something was, therefore, due to his feelings under the circumstances, as he feared that if the child in question were vaccinated the same fatal results would follow. Mr. Watson submitted that the bench had nothing to do with Mr. Doody's conscientious motive. The law was particularly explicit, and there was an obligation on the Board of Guardians to see that it was put in force. After a short consultation on the bench, Mr. Benson (the chairman), said they deeply sympathised with Mr. Doody, but it was incumbent on them to carry out the Act. Taking all the circumstances into consideration, they had determined to limit the penalty to the fine of 1s., in default the defendant to be imprisoned one day. The rev. gentleman said he declined to pay."

It should have been stated of what disease the first child did die from. It should not be a case of *propter hoc* because *post hoc*, but then these are the kind of people—the quack religious—so cheerful of spirit, with countenance beaming with holy things who make martyrs of themselves on every trifling occasion, who blow presumptuous conceit and ignorance from would-be celestial pairs of bellows, which turn out very terrestrial for all that, and very selfish in motive when the truth is known, not unfrequently having for their object the arousing of sympathy for performing the Master's work so well in disobeying the law, creating dissaffection and teaching to their flock the practical lesson and example of disobedience. A few days' imprisonment is no punishment for them. They elicit sympathy, presents are heaped upon the precious baby's head, who may live on to destroy thousands in the future by propagating variola, because of its father's combination of ignorance, obstinacy, and hypocrisy; or papa gets embroidered slippers, and pulpit-cushions to keep his holy marrow-bones from aching in the act of devotion and reverence, or what is more usual, often the stage of martyrdom, he is invited to a public piety tea-gathering, and stuffed with sally-lunns and an inexhaustible supply of infusion of mixed congou and Assam in sympathy with his police-court manifestation, in approval of his public act (which the Great Unpaid on the bench wink at), of disobedience in not only successfully evading, but with a flourish of a parson's trumpet despising and over-riding the law. Magistrates have no right to deal leniently with such offenders. The more educated the greater the offence, as in other criminal acts, and the greater the punishment, say we, should await all such scheming defaulters accordingly.

Parsley-Pie.

INTRODUCTORY to facts we are about to record, it may not be out of place to state that Parsley-pie is a very popular dish with the humbler classes of South Devon and of Cornwall generally. The pie made of meat and parsley is brought to table, a central piece of crust cut out and as much cream poured in as the dish will conveniently hold, altogether then the pie is very rich and savoury, and most popular. An unfortunate occurrence happened a week ago to a family who had prepared for dinner, and freely partook of, parsley-pie; a young girl gathered the parsley and nothing unusual was noticed until the narcotic action of conium manifested itself a short time after dinner. Upon the arrival of the doctor, a respected correspondent of ours, he had the parsley bed or border examined, when some plants of hemlock were found growing luxuriantly amongst the parsley. There was no longer any hesitation about attributing the anodyne and sickly feelings of his patients to the eating of hemlock. Emetics were freely administered and followed by stimulants, when all recovered except the youngest child, who rallied for a few days, but ultimately sank from *peri-pneumonia notha*. Had the parsley been used as a flavouring in broth, the smell and taste of this virulent poison might have been detected earlier. It (the hemlock) grew up in a new bed of parsley, so that it is to be inferred the seed was adulterated with it. It behoves seed-merchants to guard against any mixture of the umbelliferæ seeds, and all who keep gardens and cultivate parsley to examine the beds that no accidental introduction of a destructive agent may take place. The deep green shining, tripennate leaf, with furrowed sheathing petioles, readily contrasts with the parsley, and the undulating crenulated ridges without vittæ of the fruit at once distinguish it from others of its class, irrespective of its pungent odour.

FINDING that the finances of the Middlesex Hospital are in an unsatisfactory state, Sir Edward R. Jodrell has sent to the secretary a cheque for £1,000, and an intimation that his subscription will be increased from ten to twenty guineas per annum.

Public Convalescent Homes.

The machinery which is, or rather ought to be, in use for preventing the spread of disease, appears to us to be entirely deficient in dealing with one of the most contagious and fatal of our epidemics, and it seems to us that it is quite necessary that some special provision should be made, even if all the powers now provided for confining the malady to the smallest area were put in force. There is, as far as we know, no provision made by any system of sanitation for the isolation of patients recovering from scarlatina, and the result is that every case discharged from hospital as cured becomes itself a nucleus for the spread of the disease. It is obviously impossible to expect that poor parents can keep a convalescent child from contact with the rest of the family, and it really seems as if it would be better that the patient should never be separated from the family than that he should be taken away only to return in a month charged with fresh contagion. Scarlatina is indeed the only disease which so completely saturates the patient with the infection that there is great danger of communication with other persons during the period of convalescence, and there should be, therefore, no difficulty in providing a convalescent home for such cases.

Sanitation in Manchester.

The causes of the high rate of mortality which prevails in Manchester was brought forcibly under the notice of the inhabitants by Dr. Lankester last week.

The present rate of mortality in that city he said was 37 per 1,000, almost the highest in the list of those towns where the mortality was the greatest. The death-rate in Manchester had been less than 33 per 1,000, and in Liverpool less than 36, and it always rose and fell according to the activity displayed by the local authorities. Improved sanitary regulations and a better supply of water largely decreased the death-rate. At Barnard Castle, with a population of 10,000, the mortality had decreased from 33 per 1,000 to 25 since the improved drainage and water supply to that town. In this way eighty persons less died every year, to say nothing of the saving to health. He calculated that where there was one fatal case of disease there were forty persons attacked. Think of eighty times forty in a little town like Barnard Castle. Think of the agony, pain, and anxiety relieved.

The Brown Bequest.

It is announced that the University of London is at length able to carry out the provisions of the Brown bequest, and will shortly acquire the necessary ground and buildings for the purpose. It will be remembered that a very large sum of money was willed to the University for the purpose of building an hospital for sick animals, and it was provided that if the University failed within a given period to avail themselves of the bequest, it should pass to the University of Dublin for other purposes. When the time specified was about to expire, the University of London quietly introduced a Bill into Parliament to enable them to go outside the instructions of the testator in their allocation of the money; but the University of Dublin was awake to the move, and succeeded in defeating it, and the London University is now under the necessity of employing the bequest as they were directed sooner than lose it altogether.

The Fever Certificates of the University of Dublin.

We understand that two modifications will probably be made in the details of the regulations respecting certificates of attendance on fever cases, recently issued by the Medical Registrar of the University of Dublin—

1st. The forty-eight attendances recorded at hospital may be either on bedside instruction or on formal clinical lectures delivered in the theatre.

2nd. If in any case there be an objection to give the names of the fever patients (as, for example, if they be pay patients), a number may be substituted for a name in the return.

The dates of attendance and nature of fever are considered to be absolutely necessary if the certificate is to be a *bona fide* one.

Female Medical Students and the Infirmary.

The female medical students attending the Edinburgh University having recently applied for tickets of admission to the infirmary, the question whether such tickets should be issued, was referred to the managers, and that board, at its meeting on Monday week decided in the negative.

Contagious Diseases Act.

These Acts were set in operation at Winchester on the 6th of January last. During the first quarter the number found diseased among those subjected to these Acts was nearly 40 per cent.; but their seclusion has eliminated the sources of contagion so rapidly that by the middle of the present month (October) no diseased persons were found at the periodical examination, and not a single case of the diseases against which these Acts are directed was under treatment in the Military Hospital at Winchester.

Professor Alexander Simpson's Inaugural Address.

The Introductory Address of Professor A. Simpson (Sir James Simpson's successor in the chair of Midwifery) was the occasion of one of the most disorderly—not to say disgraceful—exhibitions ever witnessed. Some demonstrations of feeling on the part of the students had been expected, but few, it is to be supposed, were prepared for the systematic violation of order and decency that did take place. In the interval before the arrival of the Professor, the students—and chiefly a knot who had taken up their station in the upper benches, and who made themselves disagreeably conspicuous all through the proceedings—amused themselves by throwing peas, exploding crackers, singing, and in various other ways. When Professor Simpson entered the room, accompanied by the Lord Provost, the Principal, and several members of the Senatus, he was immediately greeted with a storm of howls and hisses, which, however, were eventually drowned in the cheers of the main body of the audience. His opening remarks, and almost every succeeding sentence, were but so many signals for fresh outbursts of noise, aided by what seemed to be an organised tramping of feet in the upper benches, and varied by occasional peas and crackers. This lasted for some time, in spite of cries of "Shame" and "Order" from the better disposed of the audience, till at length the Principal rose and appealed to the students to give the lecturer a fair hearing. This appeal

had but little effect. The uproar and tramping were resumed with as much vigour as ever; and at one time there seemed to be a fair prospect of a fight, for one of the "disorderlies," who had drawn down upon himself the indignation of those surrounding him and was threatened with ejection, stuck his bonnet upon his head, and appeared to be defying them to do their worst. Another individual managed to gain access to the garret over the class-room, and added to the confusion by shouting through the grating overhead, but one of the officials quietly turned the key upon him, and left him in durance till he could be consigned at leisure to the justice of the authorities. In the lecture-room itself a new feature was introduced to increase the disturbance, and from various quarters the melodious voice of the bird "that is the trumpet to the morn" was produced with such accuracy of imitation as to suggest the idea that the performers must have studied very successfully in the farm-yard. Professor Simpson again paused in his address, and

Professor Christison rose and entreated the students to give a fair hearing.

The address was then resumed, and though the noise and interruption continued at intervals, it was hardly so violent and sustained as it had been previously. It is only right to say that the disturbance came chiefly from a small but persevering body of the students, and that the great majority were inclined to give Dr. Simpson a fair hearing. The hissing was renewed when the Professor left the class-room.

Re-opening of the Army Medical Department.

It is officially announced that an examination of candidates for Commissions in the Medical Department of Her Majesty's Army will be held in London in the course of February next, and of which particulars as to date, &c., have not yet been advertised.

We understand that there will be between twenty and thirty vacancies to be filled up.

A chemical society, has been established at Zurich under the presidency of Dr. Wislicenus.

The Physical Laboratory lately built at Oxford is opened this term for practical instruction in physics, under the superintendence of Professors R. B. Clifton, F.R.S., assisted by two demonstrators.

The Board of Trinity College, Dublin, have expended about 2,000*l.* in draining the College park. Situate as the park is, in the very centre of the city, its drainage will confer a considerable benefit on the city.

The next meeting of the London Pharmaceutical Society will be held on December 7th, at eight o'clock. The following paper will be read:—"Pharmacy in the United States." By Mr. Robert Howden.

The Woman's Hospital and Medical College at Philadelphia has existed twenty years. Attached are dissecting-rooms and a large dispensary for the diseases of women and children. There are four male and four female professors, and the cost for education is about £50.

Small-pox is raging among the Indians in Canada.

Dr. Liebreich is now in London, and is frequently to be seen at the Moorfields Hospital.

The British Medical Benevolent Fund seems languishing. Medical men are, we fear, not rich enough to subscribe much to the Fund.

The Edinburgh students seem likely to renew the scenes caused by the evidence of Tardieu in Paris on the occasion of the entry of Dr. Simpson into his new duties.

Surgeon John Caldwell, R.N., and Assistant-Surgeon W. H. Putsey, R.N., have been appointed to take medical charge of the detachment of 300 marines which has been despatched to China.

We understand that the Managers of the Edinburgh Infirmary have appointed a committee to consider if beds can be allocated to Dr. Thomas Keith, for the purpose of performing the operation of ovariotomy, with which his name is associated. For many years past, Dr. Keith has kept up an hospital at his own expense, and has performed the operation in question for the 101st time, with remarkable success.

It is our painful duty to record in another column, the deaths of Mr. C. Loe, Surgeon of Leeds, his son's wife and daughter in the short space of a fortnight. The deceased gentlemen held the appointment of medical officer to the Leeds Public Dispensary; and this terrible calamity is greatly felt in the neighbourhood, where he and his family have long resided.

Professor Kelland in a letter to an Edinburgh paper states, that five ladies competed for Lady Amberley's Scholarship for female medical students. The number of the papers which the five sent in was twenty-eight—each lady professing five of the prescribed subjects, and one professing as many as seven. The total number of marks on the twenty-eight papers was 1,974, or an average of upwards of 70 per cent. The marking was as follows:—One paper was marked 100 per cent.; two, 90 to 99; eight, 80 to 89; five, 70 to 79; six, 60 to 69; six, below 60. None failed.

In a meeting of the Cumberland and Westmoreland Branch of the British Medical Association, on Oct. 19th, Dr. Dogson mentioned that he had used very large doses of succus conii in chorea with good effect. He had himself taken as much as an ounce and a half of the succus. Dr. McLaren, of Carlisle, speaking of nitrous-oxide gas, mentioned that two fatal cases are on record, in one of which the lungs of the patient were full of tubercles. Dr. Elliot, of Carlisle, speaks greatly in favour of the stomach pump in cases of opium poisoning.

Dr. Althaus observes that there are many cases of palsy which present insensibly to Faradisation, both muscular and cutaneous, and perfect excitability to galvanisation in the paralysed limb. It has been found by the researches of some German experimenters, that nerves and muscles

obey totally different laws in this respect; that, soon after an injury to the motive nerves has taken place, the excitability of the nerves seems to be completely gone, not only to the induced, but also to the continuous current, while the muscles only lose their excitability to the induced, but not to the continuous, current. It is, therefore, of no use whatever to treat cases of this kind with the handy little machines furnishing an interrupted (induced) current, but they should be treated exclusively by means of the continuous current.

The election of a member of the Council of the Royal College of Surgeons in Ireland, in the room of Dr. James Barker resigned, took place on Thursday last. As we mentioned in our last issue, the candidates were Dr. Mapother, Professor of Physiology in the College, Dr. Robert Smith, Professor of Surgery in the University of Dublin, Dr. Kirkpatrick, Surgeon to the North Union, and Dr. Darby, President of the Irish Medical Association. The contest for the vacant office was keen, and as the supporters of each candidate attended in force, the assemblage of Fellows was unusually large for a casual election. One hundred and one votes were recorded, and the scrutiny showed a considerable majority in favour of Dr. Mapother, the numbers being as follows :—

Dr. Mapother	37
Dr. Kirkpatrick	26
Dr. Smith	22
Dr. Darby	16

Scarlet Fever.

The *Times* has devoted its columns at great length to a disquisition on scarlet fever, from which we quote the following statistics :—The continued prevalence and the great fatality of scarlet fever in England and Wales, and especially in the London registration district, are such as to call for the earnest consideration of all classes of the public. In order to show the magnitude of the evil it will be sufficient to say that the disease in the two years 1863 and 1864 destroyed in England alone more than 60,000 persons. In 1869 the number of victims in London amounted to 5,803. In the quarter ending on the 30th of June in the present year the deaths from scarlet fever in London were 1,076, and in England and Wales 5,973; and the number registered in London has lately been about 200 weekly. The disease varies so much in character and severity, is sometimes so slight and sometimes so malignant, that it would be difficult to state any definite proportion between mortality and prevalence. If we assume this proportion to be 1 in 12—an estimate that would probably not be very far from the truth—it follows that there have existed in London during a single quarter nearly 13,000 cases, each one of which, whether trivial or fatal, would be a new source of infection to the district in which it occurred. Putting the matter in another form, and allowing each patient a fortnight of insectious activity, we may say that London maintains a permanent stock of 2,000 centres of contagion.

SCOTLAND.

The Winter Session of the University of Edinburgh was opened on the 2nd inst. by an address from Principal Sir Alexander Grant, Bart.

The Managers of the Edinburgh Infirmary have declined to issue tickets of admission to the female medical students

The Winter Session of the Royal College of Physicians and Surgeons was opened on the 1st. Dr. Joseph Bell delivered the Introductory Address.

Dr. Matthews Duncan commenced his Winter Course of Lectures "On Midwifery," on Monday. The lecturer met with a most enthusiastic reception from a large and attentive audience.

THE APPOINTMENT OF PROF. SIMPSON.

The recent appointment of Dr. Alexander Simpson in the place of his distinguished uncle, as Professor of Midwifery in the University of Edinburgh, which at the time was received with so indignant an outcry in Scotland, has borne its legitimate and most desirable fruit in a powerful movement for the reform of the Board of Curators by whom the appointment was made.

At the statutory half-yearly meeting of the General Council held last week, Mr. Alexander Gibson, advocate, moved :—

"That a representation be made to the University Court, urging the desirableness of a change in the constitution of the Board of Curators, with a view to its being made more representative of the different bodies of which the University is composed, and better adapted for the function of selecting persons to fill high scientific and educational appointments."

This motion was aimed at the Town Council, who, strange to say, have the appointment of four out of seven of the electors to University Professorships, and, in the manner of Town Councils, have jobbed, in the first instance, the appointment of the Curators, and, secondly, the election of Professors.

Mr. Gibson said the time was when the Town Council looked to gentlemen outside their own body; but for the last two or three years they had confined their election of Curators to members of their own body; and on several occasions, where there were marked differences of opinion, they found that the four Town Council Curators on the one side and the three University Curators on the other.

Professor Calderwood said he had had an opportunity—not a very comfortable one for any man—of going through a canvass for two Chairs; and he had thus had occasion to judge, from personal experience, of what could be said by those who were electors for those Chairs. He had not found any individual on those bodies who professed himself able to judge, personally, as to the claims of the candidates—(hear, hear)—and he was quite satisfied the Council would acknowledge that no man, who had any proper understanding of what University appointments implied, would at all presume to say that he was competent to form any such judgment. In regard to the constitution of the Board of Curators, he thought all the members of Council were prepared to allow that any board constituted of four gentlemen from one body, and three from another, was badly constituted. (Hear, hear.) He thought they were all unanimous in thinking that, whatever should be the constitution, four from one quarter and three from another might breed dispute and faction. He moved, as an amendment, "That a committee be appointed to consider what changes may be desirable in the constitution of the Board of Curators, to prepare a definite plan, and to submit the same to next meeting, with a view to further steps by this Council."

The Rev. Dr. Phin seconded the amendment. He was quite sure there was not in the Council an individual who would say that matters should remain as they were. The fact was that the present was the worst possible system of patronage; and that a change could not be made without being for the better. The Town Council of old administered the patronage much better than the Court of Curators. (Applause.) The election of Professors should be put in the hands of educated men—men whose minds had been cultivated by study, and who might be supposed to be capable of knowing what sort of persons should hold academical appointments.

No one could have watched the proceedings of the Town Council in selecting representatives for the Curatorial Board without feeling that the Council had been gradually making matters worse and worse. At one time the members of Council appointed as curators eminent men not connected with their own body; but a resolution was afterwards passed that they would do so no longer—that in future they would confine their choice entirely to their own ranks.

Dr. Alexander Wood occupied the peculiar *rôle* of defender of the Town Council, and pointed out that the University had continued to exist since the year 1588 under the arrangement of the Town Council, and argued that it might safely go on as heretofore.

Mr. Gibson withdrew his motion in favour of the amendment, which passed *nem. dis.*

It seems to us to have been hardly necessary to elaborate the question as the speakers did. There could be but two reasons for leaving the appointment of Academic Chairs in the hands of the Town Council—that they were the persons most competent to judge, and that, though not the most competent, they had discharged the duty satisfactorily.

The unfitness of a Town Councillor as such to appraise scientific talent and erudition may be conceded—that they have not done so to the satisfaction of the public is proved.

Having then neither suitability nor efficiency to plead, they ought not, we conceive, to be maintained in the exercise of so responsible a duty.

GENERAL COUNCIL OF THE UNIVERSITY OF EDINBURGH.

The last meeting of the Council of the University of Edinboro' was occupied with a lengthened discussion on Female Medicine.

THE MEDICAL EDUCATION OF WOMEN.

On the announcement of the Vice-Chancellor that an address from 160 students of medicine had been forwarded to him, Professor Crum-Brown moved—

"That whereas last year a resolution was passed in favour of the medical education of women in the University; and whereas it is found that under the present regulations of the University Court such education is practically impossible, the General Council represent to the University Court the desirableness of so far modifying the regulations as to afford to women the same advantages as to other medical students."

He said that nothing could be better than the result of the experiment made last session, except in one point, that it was absolutely impossible to carry it any further. There were several ways in which women might be admitted to the advantages of medical education, and he thought they might ask the University Court to determine which of these schemes was most suitable, and take such steps as might be necessary for carrying it into effect.

Professor Turner moved a negative to Dr. Crum-Brown's proposal. He confessed he did not see his way clearly to any other plan to relieve the professors from the burden they complained of than that women and men should be admitted to the same class-rooms, to hear the same lectures, and at the same hour. That seemed to be the only method of getting out of the difficulty. He had taken some pains to ascertain how the system would work, and what was the general feeling in regard to it. He would take the opportunity of reading some information he had received from one of their own graduates, who had studied for sometime at Vienna, and who wrote:—"The professors and teachers in Vienna declare that the presence of women in their class-rooms interferes with the free discussion of subjects they are to teach." The professors of the German universities boasted that no German lady by birth studied medicine there; and similarly at Pesth there were no Hungarian ladies. A gentleman, who for some months was in daily conversation with one of the professors at Zurich, was told that the members of the medical faculty were not only opposed to the principle of mixed education, but would have cancelled the arrangements in force if that had been within their power. He asked them, as men who were desirous of keeping up the tone of public morals, if it was at all decent that they should ask him, or any other man in his position, to discourse on questions of this kind to mixed audiences? Such a thing was utterly repulsive to him. He therefore moved the previous question. (Applause.)

Professor Lister seconded the amendment. He could not but believe that Professor Crum-Brown's motion virtually meant that the University Court should be asked to sanction mixed classes.

Professor Crum-Brown—No.

Professor Lister—It might be said, perhaps, that medical men were prejudiced in this matter. Of course, it was very difficult to say how far they were swayed by prejudice. He was not aware that he was prejudiced in the matter. If he could believe that women would benefit the human race by following the medical profession, he would be extremely glad to assist them. As regarded the particular question of mixed classes it seemed to divide itself into two branches—the effect upon the women studying and the effects upon the male students, and indirectly upon the school. As regarded the former point, he would content himself with saying that he believed there was not in the length and breadth of Britain a single medical man, knowing what medical study really was, who would send a daughter of his to study in a mixed medical school—(applause)—at the young and susceptible age at which medical study should be begun. Therefore, supposing mixed classes existed, the result must be that a large and important class of diseases must be withdrawn from his instruction; or, on the other hand, if, in spite of considerations of modesty, such diseases were brought before mixed classes, the result would be, undoubtedly, to produce the most mischievous effects on the morals of the male as well as the female student. If the time should ever come when he should have this forced upon him as a part of his duty, so far as he was at present able to judge, the result would be the resignation of the office which he so highly valued. (Applause.) Dr. Lister went on to read the address from 160 medical students which had been referred to by the Principal, and which conveyed thanks to the members of Council who had opposed the introduction of female students into the medical classes.

Professor Blackie said he was rather a moral sort of man in his way. He did not deal in indelicate matters; and he wanted to tell why he differed from the gentlemen who had spoken. There was a great talk of indelicacy. No more vague, unintelligible word than that was to be found in the whole English language. If they were never to mention certain matters in a mixed company, they were never to read their Bibles in their own houses. They had, he contended, no right to exclude any person from the University. The present feeling against mixed classes was the same as those people had against mixed audiencies; but what was to prevent a young man from going and sitting beside his sweetheart and holding her hand most affectionately during the whole time of sermon? (Laughter, hisses, and applause.) If they disapproved of mixed classes, other classes should be provided; but he knew of no law of the University stating that women should not receive instruction as well as men, especially as it had been proved that women had as good brains, and even far better brains than men had. If the age was so corrupted that men could not look a fact in the face without rushing into a gust of immorality, he was sorry for them; he did not know that he lived in such an emasculated generation. (Laughter.) Another point was, that, as the lawyers said, *res non sunt integræ*. Certain ladies had been admitted into the University. The authorities admitted them with the right hand and knocked them down with the left—gave them license to study medicine, but no appliances for doing it. Was that, he asked, a gentlemanly way to treat ladies?

Professor Bennett maintained that the whole argument on the other side had been irrelevant. He hoped that the University Court, through the means at their command, might devise some method by which ladies and gentlemen might be instructed in medicine, either separately or in some other way. What, then, was this great argument which told them that the study of medicine was a something utterly repugnant to modesty, that medicine was altogether a sort of shameful immodest study, which rendered it impossible for a woman to listen to it with propriety? This idea of delicacy was altogether peculiar. It entirely depended upon the manner in which the subject was treated whether it was delicate or indelicate. The view of the naked form was not in itself indelicate, but it might be made so from the way in which it was commented on. It was the duty of a University to impart knowledge to all people—to women as well as to men. What they had to deal with was human intellects, and not sexes.

He himself gave a full course of physiology to females last winter. He entered fully into all the very delicate subjects which had been referred to, and there had been no trouble whatever in the matter. It had been said that the exposure of certain parts of the body gave the feeling of indelicacy. If that was so in regard to females as medical persons, how should the same feeling not exist with respect to nurses?

Dr. PHIN, as the Council's representative in the University Court, wished that Dr. Crum-Brown would tell him what he wished the University Court to do. If he wished mixed classes, let him say so in his motion. (Hear, hear.)

Professor MASSON understood Dr. Crum-Brown's meaning to be this—that there had come to be a dead-lock in the present method of admitting women to a medical education; that the University was in a wrong position before the public in having nominally and enthusiastically consented to do a thing, but having actually left it a sham and a pretence.

Professor CHRISTISON called attention to the circumstance that the resolution of the University Court, recognizing the teaching of women by the professors, was coupled with the condition that the teaching should be given in separate classes. When this matter was brought up twelve months ago, it was stated, and it had a great effect upon the public, that the movement was patronised by the highest lady in the realm. Now, he could possibly contradict that. Not long after the meeting a communication was made to him—not a formal message, but still a message sent to him, and also to Dr. Laycock—to this effect, that her Majesty concurred in the views which had been expressed on that occasion by Drs. Laycock and Christison, that she desired that this communication should be intimated to them, and that her sentiments should be made known. (Loud applause.)

After a few words in reply from Dr. Crum-Brown, the meeting divided, when the negative as moved by Professor Turner, was carried by 47 to 46. The result was received with loud cheers.

Summary of Science.

By Chas. R. C. TICHBORNE, F.C.S., M.R.I.A.

Mem. Counc. Royal Geological Society of Ireland, Chemist to the Apothecaries' Hall of Ireland, &c.

ON THE ACONITINE ALKALOIDS.

FLUCKIGER has been examining the aconitine tubers, and gives the result of his labours in a long and valuable paper. Aconitine seems to be contained in all the European aconites with blue flowers, and in the similar species found on the Himalaya mountains. *Aconitum Lococtonum* a yellow flowering aconite is void of aconitine. True aconitine is said to have the following properties: It softens in boiling water, and colours concentrated phosphoric and purple; the colour is retained for some days, watery solutions of aconitine taste bitter, but *not acrid*. It is not precipitated by platini chloride, but gives a voluminous precipitate with potassium iodo-hydrargyrate. It dissolves readily in ether, alcohol, and chloroform. There is an alkaloid entirely different from aconitine, and of uncertain derivation, perhaps from the aconite tubers from Nepaul and the slopes of the Himalaya, Flückiger calls this pseudoaconitine. It is also known by the name of napellin. Pseudoaconitine does not soften in boiling water, tastes acrid not bitter, and does not colour concentrated phosphoric acid. It is insoluble in water, very little in alcohol, ether, and chloroform, but crystallizes from its hot saturative solution in large prisms. Dr. Flückiger, thinks that English and German aconitine are at present as supplied to the market identical.

EUCALYPTUS GLOBULUS.

THE leaves of this plant (natural order, *Myrtaceæ*), have been used successfully as an anti-periodic, particularly in Vienna. A tincture is made of the leaves, which has a pleasing aromatic taste.

THE MOST DELICATE COLOUR TEST FOR STRYCHNINE.

M. WENZELL in the *American Journal of Pharmacy* says, the best form of applying the colour test, is to dissolve one grain of permanganate of potassium in 2,000 grains of sulphuric acid, water only acts as a diluent, and besides, the solution has a deep purple colour, whilst the acid has a pale green. It was found that the limit of positive recognition by the bichromate and sulphuric acid test may be placed at 1-100,000th, that of chromic acid, 1-600,000th, and that of the permanganate 1-900,000th.

ON THE INFLUENCE OF LIGHT ON THE PETROLEUM OILS.

M. GROTOWSKI has shown that when the petroleum oils are exposed to the solar light under certain conditions, they absorb a certain quantity of oxygen, and convert it into ozone in a similar manner, to what has been observed in connection with other hydro-carbons. The oxygen does not seem to combine with the oil, but reacts energetically as an oxidizer upon substances with which it is brought in contact, thus the cork of the vessels in which it is contained, is generally acted upon to some considerable extent. After the action of the ozone, the oils boil with difficulty. The colour of the vessels in which the oil is placed, has a great deal to say to the absorption of the oxygen.—*Cosmos.*

MAGNETIC OXIDE OF IRON FOR THE PURIFICATION OF WATER.

DR. J. SCHOBER states that ferroso-ferric oxide absorbes certain salts from their solutions, providing that the said solutions are sufficiently diluted. The salts are so fixed, that they cannot be removed by washing; nitrate of lead, silver, copper, and nickel—the sulphates of copper, iron, and zinc, with stannic chloride, also organic matter, alum, chrome alum, and tartar emetic lose part of their base, but the alkali remains in solution. Baryta, strontium, and lime salts are not much affected by it, soluble salts of mercury, magnesia salts and the alkaline salts not at all, oxide of iron has a similar property, but in a much less marked degree. There are some cases where this might be used practically.

DETECTION OF ALCOHOL IN CHLOROFORM, CHLORAL HYDRATE.

M. LIEBEN uses the reaction of iodine and free potash upon alcohol, as a test for that body. The production of iodoform in microscopic crystals, is capable of detecting 1-2,000th in any liquid. Hagers' process is as follows:—The reagents used are a solution of potassium iodide in five or six times its weight of distilled water, and then saturated with free iodine, and a solution of hydrate of potassium, of about ten per cent strength. To the liquid to be examined, five drops of the latter solution are added. After warming to 50° C. so much of the potassium iodide solution is added drop by drop, that its colour after gentle agitation remains yellowish brown. Then the liquid is carefully decolourized by the addition of a few drops of the solution of potassium hydrate. When set aside, the iodoform crystals deposit, and are recognized under the microscope. The formation of iodoform is not produced by amylic alcohols, ether, chloroform, chloral hydrate, or any of the organic acids.

To determine the presence of alcohol in chloroform or similar fluid, two volumes of the chloroform are mixed with five to ten volumes of water at about 50° C. The liquid is shaken and poured upon a filter previously moistened with water. The filtrate is then examined in the ordinary manner.

Chloral hydrate is examined in a similar manner. Chloral forms with alcohol an alcoholate, corresponding to chloral hydrate in its chemical and physiological (?) properties. Since the equivalent weight of ethyl alcohol is five times greater than water, it is of considerable pecuniary advantage to the manufacturer to bring the chloral alcoholate into the market instead of the hydrate. Independently of the iodoform test if the hydrate is warm in a test tube with twice its bulk of water, it dissolves readily, but the alcoholate melts without solution, and on cooling congeals under the water. Sulphuric acid warmed with chloral hydrate remains colourless, but turns brown with the alcoholate, with nitrous acid the alcoholate starts a vehement reaction, and nitrous oxide gas is evolved, or the amount of chloroform produced by the action of potash may be directly measured.

ON GLUCOSE AND ITS ARTIFICIAL PRODUCTION.

IN the last number of the *American Journal of Pharmacy* appears an article upon glucose, which possesses considerable interest from a scientific as well as a technical point of view. It is written by C. Joy. The conversion of starch into sugar was discovered by Kirchhoff in 1811. This peculiar sugar, grape sugar or glucose, can be made in many different ways. It is probable that both cane and grape sugar are formed from the starch contained in the cellular tissues of the plant, cane sugar being formed first and then grape sugar, if acids be present. Acidulous fruits contain only grape sugar, whereas cane sugar occurs in those which are free from acids as in the sugar cane or beet. The grape vine, figs, honey, and the liver se-

crete glucose. Maubré's process is the one generally adopted for making glucose, and it consists in boiling a mixture of dilute sulphuric acid and starch-meal under a pressure of six atmospheres. The boilers are similar to those used for high pressure boilers, except that they are lined with lead and provided in the interior with a perforated tube for the passage of steam. The boiler is furnished with a safety-valve, stop-cock, and thermometer. Fifty-six pounds of sulphuric acid are diluted with 5,600 pounds of water, and heated to 212° Fahr. A mixture of the same amount of acid and water which is heated to 86° F., is taken, and into this second mixture 2·240 pounds of starch-meal are well stirred and heated to 100° F. This is gradually added to the first mixture, and, after heating with open valves for a few minutes, the stop-cocks are closed, and the heat is raised to 320° F., and continued until all of the starch is converted into sugar. This requires from two to three hours. The acid is then neutralised with chalk, and the filtered solution of glucose is clarified by blood and bone black. Another method consists in converting the starch by means of malt. However, the sugar made in this manner always retains the flavour of malt, and is therefore only adapted to use in breweries.

Glucose can be also made from cellulose, but not so economically as from starch. In this case two parts of clean linen shreds are gradually added to three parts of sulphuric acid, and the mixture is allowed to stand twenty-four hours; the whole is then largely diluted, and the sulphuric acid neutralised with carbonate of calcium. The starch of potatoes is easily converted into glucose by digesting a few hours with the parings of the potato. This is made use of practically by the German farmers in the preparation of food for fattening hogs. An excellent starch sugar is prepared from Indian corn, which yields alcohol one-eighth cheaper, and as pure as that prepared from cane sugar. Grape sugar is used to add to wine. The reducing power of grape sugar may be made use of for reclaiming photographic wastes. Fourteen parts of chloride of silver obtained from that source are treated with twenty-four parts of caustic soda, sp. g. 1·333, 11¼ parts of ammonia, and 7½ parts of honey. The mixture is allowed to stand in a warm place until all decomposed. The reduced silver after washing can be dried and melted in a crucible.

ANGLO-AMERICAN AMBULANCE.

Dr. William MacCormac, of Belfast, made recently a report of the proceedings of the Anglo-American Ambulance, to which he was surgeon-in-chief. We extract from his report the most important parts :—

"In accordance with our instructions on leaving Paris, we tried, after arriving at Sedan, to reach MacMahon's head-quarters and the front. The Vicomte de Chezelles, *Courrier des Ambulances*, acted as our guide. Through a combination of circumstances we were delayed that evening, the 30th August, at the railway station near Sedan. In place, therefore, of our going to the front, the front came to us. Then were the negotiations completed which placed us in possession of a large hospital of 384 beds on the battle field of Sedan. This piece of exceptional good fortune, the getting into a first-rate position, and into working order, just on the eve of a great battle, has enabled the Anglo-American Ambulance to render services such as no other ambulance in either army has been as yet in a position to perform during this war. Of course, during the first ten days or a fortnight we were short-handed and overworked. I find in the diary I kept that we have been sometimes working for twenty hours at a time, performing operations, noting cases, and making dressings. I have heard of surgeons working for much longer spells after battles. But it is questionable if work done under like circumstances is of advantage to the wounded. Captain Brackenbury, whose valuable aid I have already had occasion to acknowledge as it deserves, visited us on the 11th September, and shortly after his visit there flowed in upon us stores of all kinds, and during all the time we were at Sedan the French Military Intendance supplied us with rations and with wine, and with a staff of hospital servants. The keeping of an accurate medical and surgical record was, from the circumstances, simply impossible. I alone attempted it, and the result is necessarily very imperfect. At one time we had 400 cases under treatment, the majority in the hospital itself, a building of two floors, upwards of 400 feet long, but a large number also in tents stretching over some acres of ground. What harassed exceedingly our already overworked staff were the 'evacuations' made upon us of fresh patients. For example, on the 9th September, we received into our hospital 65 seriously wounded men from various ambulances. On the 12th September, 130 new cases were sent to us, 105 being wounded, and 25 being cases of fever. On the 14th and on the 15th were sent 50 fresh cases, 25 each day.

(All for secondary hæmorrhage.)

"The total number of our deaths was 117, 30 at least being from pyæmia, and many of the patients died within forty-eight hours of their arrival in the hospital. Our deaths were caused chiefly by exhaustion, by diarrhœa, by dysentery, and mainly after operation by that hideous scourge, pyæmia, which, however, was quite as common, if not more so, in the small houses and chateaux, with only few patients, as it was in our larger establishment. We had six deaths from tetanus. Without any doubt the primary amputations did much better than the secondary. When it was possible to investigate the nature of the injury within the first twenty-four or forty-eight hours, and then operate if needful, our results were infinitely better than they were when amputation proved necessary in ten days or a fortnight after the injury. With but few exceptions, we found that both the Prussian and Chassepot balls produced most extensive fracturing of bone, and the cases of bone injury in which the practice of conservative surgery was expedient were but few. I think the Prussian bullet, which is much the heavier of the two,

caused the greatest amount of damage. Our rate of mortality began to increase directly after the 'evacuations' made upon us of the 9th and 12th, and this, as well owing to the deaths amongst those sent in, as from those occurring amongst our original patients, previously in most excellent hygienic conditions. On Sunday, October 9th, there were but 15 patients remaining in the Caserne d'Asfeld, and these I transferred to the care of a Dutch ambulance, just arrived at Sedan, with plenty of both money and *materiel*, but with nothing to do."

Literature.

REPORT ON THE SANITARY CONDITION OF THE PARISH OF ST. GEORGE, HANOVER SQUARE.*

This report shows first of all that, deducting the deaths of non-parishioners (298) at some hospitals in the parish, the death rate of this parish was only 16·8 per thousand. On this, we would remark that many of the inhabitants die at country houses, and that the rate of 16·8 per thousand is on this account very misleading. In the case of zymotic diseases, Dr. Aldis has shown that diarrhœa was the most fatal. None of the cases, 141 of relapsing fever, admitted during the year into the various Metropolitan hospitals were from the parish of St. George. The specific fever of cows, called foot-and-mouth disease, which is accompanied by an eruption resembling varicella, appeared in a few cases and then died out. The Serpentine cleansing commenced in September. A great outcry was made when the operations for emptying the lake first commenced, during a few unexpected warm days, but no increase of fever took place in St. George's district. It has been determined to remove all the mud; but not to render it shallower. With regard to the Workshops Regulation Acts, Dr. Aldis is dissatisfied with the wording of the 4th Clause, which says that "No child, young person, or woman shall be employed in any handicraft on Sunday, or after two o'clock on Saturday afternoon," because this is interfered with by another clause which permits them to be employed until three in the afternoon. We question whether *women's* labour should be thus interfered with, although in the case of young girls and children, we are ready to endorse the provisions of the Bill. The protection of women now-a-days shown in the Contagious Diseases Acts, &c., looks rather like meddling and muddling. Dr. Aldis complains that there is another exception to the provisions of the Act, which renders it difficult to work it. The gas in St. George's, Hanover Square, is all free from sulphuretted hydrogen and seems to be pure.

TRANSACTIONS OF ST. ANDREW'S GRADUATES ASSOCIATION, 1869.†

This is a most tasteful volume, bound in blue cloth, and with excellent paper and type. We propose to notice a few points in the various excellent papers it contains. First of all, there is a memorandum on the criminal responsibility of the insane, in which it is contended by Dr. B. Richardson that the law concerning persons alleged to be afflicted with insane delusion who have committed a crime, should be submitted to a Royal Commission. Next, there is a memorandum on the advantages to be derived from a registration of disease. Then follows an oration by Dr. Richardson "On the Science of Cure." Most of our readers have read this eloquent address at the epoch of its delivery in our pages. Dr. Black, M.D. St. Andrew's and London, gives an essay "On the Clinical Examination of Urine in Relation to Disease." Dr. Black takes 40 ounces in the twenty-four hours as the normal quantity of urine passed by healthy adults. In hysteria, patients pass frequently in a few hours as much as three or four quarts of urine of a specific gravity as low as 1,007. Diabetes mellitus is sometimes present, with no increase in the amount of urine passed. There is no disease in which the density of urine fluctuates so much as in phthisis pulmonalis; but in the acute forms it has a high specific gravity, 1,026-28 being frequently met with. The urine of neuralgia, of hysteria, and of rheumatism have one character in common—that of a pale colour; but here the analogy ends. With regard to phosphatic urine, Dr. Black describes it as of the lightest shade of the standard colour of urine, with a dash of white in it. It is frequently the result of wear and tear of the nervous system. Occasionally, sugar, phosphate, and oxalate of lime and uric acid, in crystals, may alternate with each other. Chyle is sometimes found in urine, in warm climates especially. In such cases, a quantity of fat in a molecular form is found in the urine. When pus is present in urine, the fluid, on standing, becomes separated into a supernatant part and a white sediment, which, under the microscope, is seen to consist of pus globules. If pus occurs in the male in pretty large quantity, the pelvis or the tubuli urineferi of the kidneys are probably diseased. If the bladder be affected, thick viscid mucus accompanies it in most cases, but not in all. In the female, the colour of the urine may be rendered milky in appearance not only from such causes, but also from inflammation of the mucous membrane of the vagina and uterus. In oxaluria, the colour of the urine is usually deep amber, and the density varies from 1,025 to 1,030, and such urine is common in professional persons. Yellowish red and brownish red urine is essentially the urine of inflammation. The depth of colour in inflammatory urine is due to an excess in the pigment matter of the secretion, and its increased density to the presence of an increased quantity of urea. In acute rheumatism, the colour of the urine is described a deep lake red and of specific gravity 1,028-30. This will often assist us in diagnosis of rheumatic affections. When urine, containing either albumen or sugar, is shaken in a bottle which is afterwards kept corked, the head of the air-bubbles thus produced will not break and subside for upwards of twenty-four hours. When the urine of disease contains no other than the ordinary constituents of urine, the capability of aeration is in proportion to the quantity of organic matter present in the urine. The appearance of an urate deposit in the urine in disease is generally indicative of a tendency towards recovery in fevers or in inflammations. Diabetes mellitus is in no way a disease of the kidneys themselves; and however long a case of diabetes may have existed, however much sugar there may be in the urine, and however fractional the natural solids of the urine have been reduced by this disease, hope of recovery under judicious treatment may be entertained. In pulmonary consumption, the presence of urates is significant of the progress of the disease to a fatal termination. In galloping consumption, the urates are always found. In all diseases of the stomach, in which excess of acid is secreted by the organ, deposits of uric acid are apt to occur in the urine. In irritable dyspepsia, in pyrosis, and in the early stage of organic disease of the stomach, this is of frequent occurrence. The stomach, in such cases, secretes an excess of uric acid; this passes into the blood, finds its way to the kidneys, is eliminated, and passed off in the urine, in which it displaces the uric acid from its combinations, and causes it to be deposited in a crystalline form. Professor Polli, of Milan, after experimenting on himself with haschish, and finding that this drug gave feelings of happiness and self-satisfaction, tried it in a case of melancholia. He commenced with a dose of about fifteen grains of the brown

* Report on the Sanitary Condition of the Parish of St. George, Hanover Square, ending March 26th, 1870. By C. J. B. Aldis, M.D. Pp. 19.

† Transactions of St. Andrew's Graduates Association, 1869. Edited by L. W. Sedgwick, M.D. Lond. Churchill, 1870, pp. 306.

extract to be taken at dinner time. In ten days the patient took seventy-seven grains, and she was soon in perfect health. In a case of hydrophobia, the patient was made to swallow seven grains of the extract every four hours. In twenty-four hours he took two-and-a-half grammes of extract of Indian hemp by the mouth. This alleviated his sufferings, although the result proved fatal.

Dr. Cholmeley contributes a paper "On the Therapeutic Influence of Chloride of Ammonium," a drug which in Germany has long been used in fevers and chronic disease. The author of the paper asserts that the chloride is of great service in some cases of *neuralgia*, in doses of fifteen grains t. d., or, if the pain is very severe, thirty grains. In some cases of tic doloreux and hemicrania, it is alleged to act like a charm; in nervous head-ache, too, he finds it very useful, and in myalgia. The author of the paper has found the chloride of great use in sciatica in one form of it, and he also recommends it in lumbago. In amenorrhœa, also, it is, he says, to be recommended; indeed, he fears to order it during pregnancy on this account. In dysmenorrhœa, too, he has found it useful.

There are papers by Dr. Lloyd Roberts, of Manchester, "On Ovariotomy," by Dr. Hughlings Jackson "On Convulsions," and by Dr. B. W. Richardson "On Intermittent Pulse," which require careful reading, but do not admit of extracts being made from them. Altogether, we congratulate the graduates of St. Andrew's on this excellent record of their annual meeting. It is a great pity that the method of granting degrees by St. Andrew's University were not universal. If ever we are to have a state-degree, it must be like, in many respects, to the one formerly carried out at that Scottish University, neither implying residence nor any other trash of like nature.

Correspondence.

CAUSES OF PROSITUTION.—SEDUCTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In connection with the subject of Baby-Farming, which has lately been discussed in your columns, that of Seduction has incidentally sprung up, One correspondent, Dr. Waring-Curran, insists strongly upon the excessive prevalence of seduction over all other causes of the loss of female honour; while another "Veritas," writing apparently from a special knowledge of the question at issue, objects to Dr. Curran's sweeping denunciation of the male sex.

Without professing to have closely studied the intricate windings of the road to ruin, I venture to suggest that the statements of writers of experience in such matters go far towards showing that "Veritas" is much nearer to the mark than Dr. Curran.

I will not attempt to occupy your valuable space by bringing forward more than one authority in support of the views advance by "Veritas," and that authority is Mr. William Tait, formerly house-surgeon to the Edinburgh Lock Hospital, and author of "An Enquiry into the Extent, Causes, and Consequences of Prostitution," published in 1841, and now a somewhat rare work, so that I may be the more readily excused for quoting from it.

The extent and consequences of prostitution need not be dealt with here: they are matters which are obvious enough to anyone who has lived in a populous place, and I shall limit my letter to the causes which lead to the deviation of a considerable number of females from the paths of virtue.

First, as regards seduction. Under this heading, Mr. Tait, who had exceptional opportunities of obtaining statistical information concerning the causes of prostitution, and who, judging by his work, must have applied himself energetically to his task, says:—"Seduction is believed to be a very general cause of prostitution. The investigations which the author has made, relative to this important subject, have led him to a different conclusion. . . . . By seduction, is to be understood the act of corrupting, tempting, or enticing females from a life of chastity, by money or false pretences, solely with the intention of gratifying the lust or amorous propensities of the opposite sex. If the instances of seduction be brought to the test of this definition, it will be found that they are comparatively few. . . . So far as can be ascertained, about eighteen per cent. of all the common women have become prostitutes in consequence of seduction. (Second Edition. 1842. Pp. 141-143).

This can scarcely be considered a very large percentage, and, *mutatis mutandis*, I should be disposed to put the relative proportion of George Barnwells, and other young men, corrupted by depraved persons of the weaker sex, in excess of this.

Next, with respect to the love of finery and dress, as exercising a strong undermining influence upon female chastity, permit me to make another quotation from Mr. Tait's work (p. 119)—"There is not, perhaps, in the lengthened catalogue of causes of prostitution, one more general or more powerful than ambition for fine dress. It is one to the influence of which all women are in a considerable degree subjected. The desire to appear more gay than her companions, is a prominent feeling in the breast of every female child; and it is strengthened rather than diminished when she attains the age of maturity. As her acquaintances multiply, and as she begins to court and delight in the society of the opposite sex, this desire becomes more and more excited, till the ambition of appearing fine oversteps the means of doing so. Unless the feeling is curbed at its commencement, or the restraint of a powerful and well-regulated mind is called into operation to check its influence when once matured, some extraordinary means must be adopted, in order to satisfy it; and no method holds out a more encouraging prospect of success than a life of prostitution."

I have already trespassed further upon your space than I had intended, and I must therefore only refer to other not uncommon causes of the loss of female virtue, such as the natural inclination to vice which prevails in some persons of either sex, and pride and indolence, which often cause women to part with their chastity in preference to following laborious, honest callings.

I have, however, said sufficient to show that I do not agree with Dr. Waring-Curran in his unqualified attack upon the male sex, and, indeed, I think that he, according to his last letter on the subject, is more disposed to throw deserved censure upon a certain class of individuals, whose chief aim in life appears to be the subjugation of virtue to vice, than to charge the masculine half of humanity with wholesale depravity.

I am, Sir, yours, &c.,
Abbotts Smith, M.D.

7 Princes street, Hanover square, London.

ONE WAY TO CHECK BABY-FARMING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Allow me to suggest to those benevolent persons who are exerting themselves in order to establish a society for the PROTECTION OF INFANT LIFE, and to others interested in the various questions which belong to the subject of "Infanticide," that little good will be done by the enactment of any laws unless it be understood that the most searching investigation will be made, and the fullest publicity given concerning such cases as those which have recently come to light, and some of them even now are under judicial inquiry.

All possible information should be brought forward, including the names of all the persons mixed up with baby-farming cases. With that object in view, an inquest should be held in every instance of a child dying at nurse, or under suspicious circumstances, even in the charge of its mother; and the aiders, abettors, or connivers who are concerned in such a system should be held up to public scorn and loathing—no matter what their position in "society"—in order that *all* the guilty parties may receive their proper share of the blame and ignominy of their evil deeds.

I am, Sir, yours obediently,
M. A. B.

SEDUCTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—With "Veritas" I quite agree that man is not always the primary cause of virtue's downfall. Your much es-

teemed correspondent Dr. Waring-Curran is more gallant than just, when he asserts that girls are, for the most part, always wantonly and deliberately seduced; such is not the fact, and so would statistics prove, could they be taken, but I am sadly afraid the opponents of the Contagious Diseases Acts will allow me no opportunity of proving the above. Suppose we take a hundred courtesans and learn the history of their individual downfall, the facts that would be revealed would be so astounding, so incomprehensible, so shocking, that they would scarcely be credited. My experience amongst our fallen sisters leads me to suppose that 25 per cent. only are genuine examples of wilful and premeditated seduction, that is, where deliberate and systematic villany on the part of the male sex has been brought into play. The other seventy-five are made up of the women who have of their own free will gone on the town out of sheer liking for the life, and of others the prey of their own sex, in some cases, alas, where the female reprobate of a tempter, literally the seducer, has been their own near relative; truth is stranger than fiction, and in many cases it is hard to hear it spoken as it is in this case, but it should not lead us into the error of putting the blame on innocent persons to shield the guilty, even if they be mother, aunt, sister, or cousin. Yes, I maintain that women as seducers outnumber the men. Girls who have already partaken of forbidden fruit and found it agreeable to body and pocket, by appearing in fine clothes, good spirit and health, excite the jealousy of their associates who want to know how they get all these good things; of course they are told, and are persuaded that it is a jolly life, and advised to do likewise by those who have been their school-friends, their fellow-servants, their factory-mates, their fellow shop-assistants, and they do go and do likewise, and in their turn become the tempter, the betrayer of their own sex, and it is thus that the ranks of prostitution are recruited. Another cause of seduction is, the innate vanity of women who love to be made much of, especially by those who may be in a station superior to themselves in society, as in the case of illegitimate children, you often hear the relatives say, "Never mind, my dear, the father's a gentleman, that's a comfort," and many girls prefer being the mistresses of rich men than the wives of poor ones, let those who deny that statement just take facts and dispute facts if they can, perhaps they may make black white; I can't! With regard to the aristocracy being so bad, they are no worse than other classes, but only let such be caught tripping, of course theirs is a most heinous fault, on the principle that the more respectable one is, the more one's shortcomings are magnified and commented on. The letter of "Veritas" on the "Victims of Seduction," is at once truthful and to the point, he must be well acquainted with the subject he wrote upon in all its bearings, or he never could have worded his letter as he has done, it is not in the least overdrawn, and certainly should be read by all interested in ameliorating the social evil. One bad woman amongst her sex is more dangerous than ten men, because in the case of the latter, girls would be on their guard; whereas, in the former, no such precautions would be deemed necessary, and the poison would be so gradually instilled into hitherto pure minds, that it would never be detected until it had borne fruit, and then the mischief's done. Widows have fallen, and will do so again, and married women prove untrue, as they do, and that only makes matters still worse for the fair sex. Surely, widows and wives are old enough to withstand the various arts and devices resorted to by the seducer who wins them from the path of rectitude. I am of opinion in such cases there must be six of one and half-a-dozen of the other. Make seduction a criminal act if you like, but punish the seducers if you please, and in some cases it will be the women. Have there been no cases of servants tampering with their young masters? I really cannot answer that question personally, but I know some who can, designing servant-maids are not over scrupulous how they inveigle a youth into an intrigue, perhaps thinking they can make a match of it, or at any rate, a case by which they may benefit themselves. I by no means apply the above to all servants, only to the few, the only thing I wish understood and known is, that man is not the *only* sinner and the sole means by which girls are tempted and fall. The callous indifference of some girls when speaking of their first sin, and the nonchalance with which they talk of the life they are leading, and how much more they could put in their pocket if they could only get a better start, *i.e.*, live in a larger house and keep their brougham, dress more expensively, &c., speaks volumes; it is very amusing to hear them talk, but, at the same time, it is horrible to know there are hundreds of young women who prefer to live in riot, and to them affluence, rather than endeavour to gain their living in an honourable manner, in fact, they glory in their shame, and some of the more fortunate ones will even condescend to pity the hard-working wife, and will answer when reproached, that she is not a low woman if she is gay, she's a swell at it, and sure enough in gay life there is the "caste" as it is in every-day life, one courtesan takes precedence of another, and the Brompton or St. John's Wood woman would feel she had lost caste if she had shaken hands with an unfortunate inhabiting the East-end of London.

I am, Sir, yours, &c.,

HENRY W. WILLIAMS, M.D.

168 Fulham road, S.W.
Nov. 3, 1870.

Medical News.

Royal College of Physicians of London.—At the ordinary quarterly meeting on the 27th ult., the following gentlemen, having passed the required examinations, were admitted as Members:—Thos. Lauder Brunton, M.D., Edin., Davies street, Berkeley square; James Keene, London; Robert King, M.B. Camb., Middlesex Hospital; John Murray, M.D. Aberd., Bryanston street; John Frederic Nicholls, M.D. St. And., Devizes; David Wm. Williams, M.D. St. And., Lynn.

Apothecaries' Hall, London.—Pass List—On Thursday, the 3rd inst., the following were admitted licentiates of the Society of Apothecaries, viz.:—Messrs. J. H. Clarke (Sheffield School of Medicine); E. T. Hale (Bristol School of Medicine); John Marshal (Guy's Hospital); and G. T. Willan (Guy's Hospital); and at the same Court Messrs. H. M. Maybury, of St. Thomas's Hospital, and E. R. Morgan, of King's College Hospital, passed the primary professional examination. At the recent competitive examination for the prizes given annually by the society to third winter session students for proficiency in the knowledge of the materia medica and of pharmaceutical chemistry the successful candidates were—1st. Joseph Henry Philpot, of King's College, gold medal; 2nd. Charles James Hislop Warden, of St. George's Hospital, silver medal and book.

The Regius Professor of Medicine at Oxford (Dr. Acland), has given notice that examinations in the first or scientific, and in the second or practical, portions of medical study for the degree of Bachelor of Medicine, will be held early in December. Also, that early in next term there will be an examination for a Radcliffe Travelling Fellowship.

Bequests.—The Hon. Augusta Irby has left £500 to the Northampton General Infirmary; Miss Catherine Stanley has bequeathed £50 to the Warnford Hospital at Leamington; and the late Baroness Wenman £500 to the Oxford Infirmary, and £100 to the Deaf and Dumb Asylum, Old Kent-road.

Society for Relief of Widows and Orphans of Medical Men.—An ordinary general meeting of the above society, was held at the rooms, 53 Berners street, on Wednesday, Oct. 26th. The chair was taken by the President, Dr. Burrows. The attendance of members was more numerous than of late at general meetings, showing it is to be hoped, an increasing interest in the affairs of the society, taken by those most concerned in its welfare. After the usual reading of minutes of the Annual Meeting and of the Courts of Directors, the acting treasurer's half yearly statement of accounts was read. The receipts of the half year available for payment of grants and expenses, amounted to £1,590 7s. 8d. the grants and expenses to £1513 9s. 1d. leaving a very small balance in favour of the society. A sad falling off was manifest in donations, the total for the half year being only £65 11s. 0. Mr. George Cooper of Brentford, was unanimously elected as Vice-President, in the place of Mr. Bacot, deceased. The proceedings terminated by a vote of thanks to the chairman.

Dr. Humble and Dr. Embleton have been appointed medical visitors of the Dunston Lodge Lunatic Asylum, near Gateshead, Durham.

The difficulty, says *Nature*, of providing funds for the establishment of a Professorship of Physical Science in the University of Cambridge has been overcome by the colleges, at a meeting of their heads, taking upon themselves a quota of the rates for improvements and other purposes in the town of Cambridge, which was formerly charged upon the University funds. This sum amounts to more than twelve hundred pounds per annum; so that the University will speedily be able to avail itself of the munificent offer of the Duke of Devonshire, and will doubtless proceed at once to establish a Professorship of Physical Science, and obtain the other aids in the way of laboratory, apparatus, and assistants, that the Professor may require.

The Conservator of Forests in India, states that the ipecacuanha plants in the gardens at Nelamboor are doing well, and that some of the fleshy leaves were four inches long.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

⁂ We must also request our Correspondents to write only on one side of the paper and in *legible* characters. We are often compelled to consign MSS. to the waste-paper-basket merely because it is illegible.

Correspondents not answered in the current Number are requested to look to the Notices the following week.

A. R.—The subject has been already discussed by us.

Dr. P., New York.—You shall receive the supply before leaving Liverpool. Thanks for your promise to push us in America; already we circulate extensively there.

Spes.—All who fail complain. Try again. *Nil desperandum.* We cannot take up your grievance. Persevere.

Drei.—The curious history of the so-called *Drei* appeared in the *Times* some years ago. Of course it was fiction.

Pater.—You must refer to our "Student's Number," where all the information you require is given. We cannot recommend any particular hospital or school.

Speranza.—We know nothing of the gentleman. The name is in the "Directory" for this year.

James R—, Esq., Cheadle.—Consult a physician, or if you come to London, see Sir Thomas Watson.

Medical Student.—There is no recorded case of poisoning by chloral hydrate. We do not know that it might not in the dose you mention. Experiment.

THE SICK LION SYSTEM.

To the Editor of "The Medical Press and Circular."

Sir,—I thought your much admired remarks on the "Sick Lion System" would have cured a certain class of journalists. Upon my word it is most unprofessional, most uncourteous, and very cruel these sensational paragraphs—the puff oblique. When will they end? We, the Profession, must at once not only despise and denounce them, but take active measures to suppress them. Our beloved Princess Louise sprains her ankle two weeks ago. We all know that, but I make a mountain out of a mole-hill, and to try to make the case alarming, we have another "Napoleon" paragraph. What will the Manchester *Punch* say to this? Surely, Mr. Lister disapproves of it as much as I, and as you, Sir, do. Our spirited young Lorne will knock the heads of some if they don't mind.

I am, &c.,
A Scotch Physician of Twenty Years.

Edinburgh, Nov. 5th, 1870.

HOW TO TAKE CASES.

Our attention has been called to a very excellent little shilling work for taking cases at the bedside, published in London by Messrs. Baillière, Tindall, and Cox, and in Edinburgh, by Maclachlan and Stewart, which is most extensively patronised at some of the hospitals. The work is ruled in a very convenient form, and with the simple instructions furnished at the commencement, will be found most useful to all whose practice or studies lie within the walls of an hospital.

THE LONDON MEDICAL SOCIETIES.

Wednesday, (this evening.)

Hunterian Society.—7½ p.m. Meeting of Council.—8 p.m. Dr. Peacock, "On the Leper Hospital at Lisbon."—Exhibition of Pathological Specimens and Discussion of Miscellaneous Cases.

Royal Microscopical Society.—8 p.m. Mr. S. J. M'Intire: "Notes on the Minute Structure of certain Insect Scales."

Friday, the 11th.

Quekett Microscopical Club.—8 p.m.

Clinical Society of London.—8½ p.m. Mr. Pollock: "Report of Cases of Skin-grafting and Skin-transplantation."—Mr. Durham, "On a remarkable Case of Spontaneous Fracture of the Femur."—Dr. Wiltshire, "On Paroxysmal Hæmaturia."—Mr. T. Smith, "On the Nature of the so-called Congenital Tumour of the Sterno-Mastoid."—Dr. Handfield Jones, "A query as to the Safety of Subcutaneous Injections."

Monday, the 14th.

Medical Society.—8 p.m. Ordinary Meeting.

Tuesday, the 15th.

Pathological Society.—8 p.m. Ordinary Meeting.

VACANCIES.

Stockport Infirmary.—House-Surgeon. Board and residence, but no salary.

General Hospital, Birmingham.—A Physician, a Surgeon, and for the office of Resident Registrar and Pathologist. Salary for the latter appointment £100.

Dursley Union.—Medical Officer. Salary £60, exclusive of fees.

Homerton Fever and Small Pox Hospitals.—Resident Medical Officer for each. Salaries £350 and £300 respectively, with residence.

Ardwick Dispensary.—Senior House-Surgeon. Salary £100, with residence.

General Hospital for Sick Children, Manchester.—Assistant Medical Officer. Salary £170 per annum. See advertisement.

Coventry Hospital.—House-Surgeon. Salary £100, with residence.

North Witchford Union, Cambridge.—Medical Officer. Salary £50, fees extra.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Mortality of Childbed and Maternity Hospitals. By J. Matthews Duncan, M.D. Edinburgh: A. and C. Black.

FRACTURE OF LEFT THIGH, ALSO OF PUBIS, TO THE RIGHT OF SYMPHYSIS, WITH PUNCTURE OF BLADDER.—A RECOVERY.

By Francis McEvoy, L.K.Q.C.P., L.M., M.R.C.S.E.,

Medical Officer Balbriggan Dispensary, &c., &c., &c.

I was requested to see, by presentation of a red ticket, a man named P. C., who, I was informed, when returning from Dublin market the night previously with his horse and cart, fractured his thigh about the middle, and otherwise injured himself, as his urine was quite bloody. How it occurred could never be satisfactorily accounted for, as he was quite intoxicated at the time, and it was several hours after the accident that he was found lying near a wall, and the cart upset beside him. The horse managed to get loose, and came home, which alarmed his friends, who immediately went in search of him, and had him conveyed home on the cart which was unbroken. When I saw him, he was lying on some straw on the earthen floor stupidly drunk. It was easy to see that his thigh was fractured; it was enormously swollen, and bent at an angle of about forty-five degrees. As nothing could then be done for him, he being without sense or reason, and most violent when aroused from his stupor or touched, I considered it better to leave him until he slept off his debauch, and recovered his reason, which did not take place until late in the evening. In the meantime, I got everything ready, as I had desired his friends to send for me when he should recover, which they did. On seeing him the second time, he had slept off his intoxication, and reason had resumed her seat. He was moaning most piteously, and when questioned could not give any account of what had happened to him—how, when, or where it occurred, whether he was beaten or not, nor tell anything whatever about the matter, as he was too hopelessly drunk; but as all the money he had received (£2) was found correct, the occurrence was considered accidental. I proceeded to examine him; first had to cut off his clothes ere I could see what were the injuries he had received. There could not be the least doubt about the thigh being broken, and when I tried to move or get the fractured leg into position he would scream out, and most piteously entreat to be left alone. In the same way with the good leg (which was quite paralysed), for the least attempt to rotate the thigh on the pelvis would cause him the most excruciating torture. At first I thought he had injured his spine, but as the sense of feeling and voluntary motion of the muscles of the feet and toes were perfect, I saw that I was wrong in my surmise, and finally considered that an injury was done to the pelvis somewhere about the symphysis pubis, and that the bloody urine was perhaps the consequence, which he passed with great pain and difficulty, and which he did not refer to the urethra, but immediately behind the pubis.

As it was quite impossible to move, or even touch him, without his screaming most terrifically, or reduce the fractured limb, I was obliged to put him under the influence of chloroform, and whilst in that state had him conveyed to a proper bed prepared for him, and instituted a most rigid examination of the spine, pelvis, and the whole man, and came to the conclusion that my latter supposition was the correct one, as I could distinctly detect a crepitus to the right side of the symphysis pubis.

He had a livid mark and swelling just over the fracture as if the horse had laid his hoof upon it; moreover, his trousers were torn and soiled with the gutter of the road, which corresponded with the livid mark and swelling on the pubis. Reduced the fractured thigh, put on splinters that would admit of counter extension, pads, straps, and buckles, and firmly bound him round the pelvis with a good strong binder. As soon as the effects of the chloroform had passed away, with the exception of a slight giddiness and nausea, which remained for a short time, he said he felt quite comfortable; nor did he complain of the counter extension I used (but on the contrary it seemed rather to give him relief), which I daily increased, and in two or three days had it as long as the good leg. I gave him an opiate and left. He suffered considerably the first night,

and indeed for the first week, from pain, when he would go to stool or micturate. Although I had given him an opiate draught, I was called up twice the first night in consequence of the frequency of the calls to make water, and I had to introduce a small sized catheter, No. 7 gum-elastic, and draw off about half a pint of bloody urine which relieved him much; and I considered it advisable to secure it in the bladder, and allow the urine to drain into a wide-mouthed bottle to keep the bed dry. I withdrew the catheter every second day, and at the end of a week he no longer required it. From this time he progressed steadily and favourably. In seventy days he was able to go about on crutches, and in six months he was quite recovered, without the least shortening or lameness. The only thing he complained of was, that occasionally he had an uneasiness about the region of the bladder, which did not amount to pain exactly, but to an indescribable sensation, and at such times (not always) he would pass a few drops of blood.

In twelve months after the accident, as I was walking one day in the street, he accosted me, and said that he had been at my house wishing to see me as there was something the matter with him; that he could not pass urine as well as he could a week ago; that he considered there was something in the passage that prevented its coming, as the water would force this something (whatever it was) as far as the nut, that there it would stop, and the urine collect behind it; and when the urine would drain off it would go back towards the bladder, during which time he would suffer considerable pain. I, at first, pooh-poohed the idea of anything being in the urethra, as he described it, going backward and forward, and endeavoured to persuade him that it was all nervousness. I, however, immediately returned, examined the urethra externally, and by rectum, but could not detect any foreign body in it, and was in the act of introducing a silver catheter, when I asked him to endeavour to pass water, which he did. Then, indeed, I could perceive something passing beneath the skin along the urethra (which I considered at the time to be a calculus) to about three-quarters of an inch of the glans penis, where it stopped, the urine collecting behind the obstruction and swelling the urethra. I immediately took a fine silver probe, and having bent it into the shape of a hook at the point, passed it into the canal down to the foreign body, against which I felt it grating—got the hook behind it; what between the pressure of the water, and using gentle traction with the probe, I managed to get it within half an inch of the meatus urinarius. The man at this stage fainted, very opportunely, which rendered its extraction much more easy. I then took a narrow-bladed forceps, passed it into the urethra, and seized the substance in the most favourable position possible, and extracted, to my no little amazement, a small splinter of bone somewhat like a small fragment of the thigh bone of a chicken.

The natural inquiry that presented itself was, whence came that bone? How did it get into the urethra? At first I considered that some evil disposed person had passed it into the urethra whilst he was in a state of intoxication and asleep (as some boys once did to a poor idiot whom they found lying drunk in a field near this town with his person exposed. One of them having an eight or tenpenny nail in his pocket passed it into the urethra and ran away. Seeing some blood trickling from his penis, his mother found him a short time after with the point of the nail protruding from the urethra, she brought him to my father, who held the situation I now hold, and he extracted the nail to the no small astonishment of the bystander; and, as murder will out—except in Ireland—the boys quarrelled some time after, and discovered on one another). But this man assured me that he never had since the accident occurred tasted intoxicating liquor.

Several other hypotheses suggested themselves to my mind to account for the bloody urine at the time of the accident. Could it be that this spicula bone had become detached from the posterior or inside of the fractured pubis, and wounded the *distended* bladder, for it had been so, and very much too? But if the bone had punctured the viscus, would there not have been infiltration of urine, or might it not have remained in the bladder, and acted as a sort of plug, or wounded the bladder obliquely, the mucous membrane acting as a kind of valve, and so prevented the escape of urine into the surrounding tissue, for I am certain that there was no infiltration into the cellular membrane. If there had been there must have been more or less constitutional disturbance—abscess and urinary hectic to indicate its presence, but there was none.

The foregoing is interesting, not only from the nature of the injuries which were received, but from their obscurity, complicacy, and difficulty of diagnosis, its presenting many phases at different times, all resulting in my opinion from the same accident; but also showing the value of chloroform in enabling the surgeon to form a correct diagnosis of his case, which could not have been done without its invaluable assistance, as his cries were the most terrific I ever heard.

The simple fracture of the thigh would have been nothing, were it not complicated with fracture of the ramus of the pubis, and whether it extended through the obturator foramen, fracturing the opposite side, or not, is more than I can say; but I think not, although the binder I put on afforded decided and immediate relief, as also the extension of the leg. The hæmorrhage from the bladder must have resulted from some lesions, and which I attribute to the wounding of that organ by a spicula of bone. I may be condoned for saying that I felt proud of the correctness of my diagnosis, as the result proved, from the passing of a bone through the urethra in a year after the accident occurred.

Now comes the most curious phase of the case, and if the foregoing was not sufficiently confirmatory of the correctness of my diagnosis, the following circumstance would sustain it. On the 7th of July last, this man came with a friend of his, who had cancer on his lip, and which I was to remove on that day, and did.

Whilst waiting for me, he consulted my assistant and Dr. Johnston, who was also waiting my advent, and told them he was sure there was something in the passage that prevented the water coming; that it came very slowly, and not in a continuous stream, but used to follow in a sort of dribble from the meatus urinarius, and that he was afraid to show it to "the governor," as he called me, lest I might cut it out as I did the piece of bone some years ago. In making this statement, he was mistaken, as I have mentioned in the former part of this paper how I extracted it. They examined him, and discovered a hard substance in the passage near the scrotum. Having asked him to make water, they could perceive a something passing along the urethra to the nut or glans penis, where they imprisoned it; got a silver probe, bent it at the point in the form of a hook, as I did before, passed it into the urethra, and extracted a triangular piece of bone, after which he made water as well as ever—and "went on his way rejoicing."

This made the second piece of bone passed in ten years after the accident, and nine years after the first came away.

He is now apparently quite well.

CLINICAL MEMORANDA.

SUBCUTANEOUS INJECTION OF MORPHIA, WITH CASES.

Reported by JOHN W. MARTIN, M.D., Assistant-Surgeon to Mayfield Factory Dispensary.

(*Continued from page* 242.)

CASE 3.—*Pulmonary Phthisis.*—J. O., æt. twenty-eight, subject to repeated attacks of bronchitis, both lungs deeply engaged, exhibiting the physical sign of cavities, probably the result of bronchiectasis at the apex of left lung, and every gradation of crepitation, from the very

fine to the large coarse and moist in character. Judging from the train of symptoms that presented themselves, the case was one of phthisis, the result of repeated inflammatory attacks. His business engagements required that he should be absent from the works where he was engaged as short a time as possible. On the first occasion of trying the hypodermic injection of morphia, he had got fresh cold, with added thoracic symptoms, feverishness, inability to sleep, quickened pulse, headache, and general restlessness. At bed-time I administered hypodermically one-third of a grain of morphia. At the expiration of ten minutes the good effects became apparent; a sense of tranquillity replaced the previous feverish restlessness, and next morning I had the satisfaction of hearing that he had had a good night's rest; the symptoms of cold had so far left him as to allow of his following his usual occupation.

On the second occasion of administering the injection, it was more as a preventitive than a curative measure that I used it. After great exertion and excitement, in consequence of a fire occurring in the mill where he is engaged, and at which he was wet through and thoroughly fatigued, he had a great tendency to feverishness, and was very restless. On his going to bed, I again injected one-third of a grain of the morphine. It did not induce sleep, but produced great tranquillity and rest. Next day he was not nearly so much fatigued as he would have been, and felt no bad effects from all he had passed through. No doubt his escaping so well was in a great measure due to the excitement, but I think some influence for good may be fairly ascribed to the morphine.

Case 4.—*Pericarditis pleuritis, and emphysematous condition of the lungs.*—John Maher, æt. forty; had got no sleep for over five nights; coughing produced fearfully racking pains in the legs, loins, back, and shoulders; could not draw a deep breath as he felt a *catch* in the chest at various points, and severe pain at the ensiform cartilage; heart's impulse seen and felt at the epigastrium; abnormal resonance strangely marked over both lungs, respiratory sounds feebler than normal; normal position of præcordial dulness, yielded abnormal resonance on percussion, showing displacement of the heart's apex downwards, and to the right side. Crepitation and friction over and on a line with left mamma; feverish, hot and restless; pulse 132; tongue white and furred; bowels acting; anorexia; cardiac action excited, sounds exaggerated, and a friction sound, distinctly marked, heard over the ensiform cartilage. At nine o'clock, p.m., on visiting him, had a blister to the chest since three o'clock, and had taken one one-eighth grain dose of hyd. bichl. in solution. Felt some ease from the pain, but was very hot, feverish, and restless; and, if dozing, starting from his sleep every five minutes. I injected ¼ of a grain of morphine into the arm, at insertion of deltoid; he was asleep in ten minutes, rested quietly the whole night, felt some thirst, but no sinking or tendency to nausea. Next morning, on visiting him, was quite tranquil; pulse 116; sleepy; felt some return of appetite for food, a thing he has not felt for a week past; makes a deep inspiration without pain; no inclination to cough; cardiac and pleuritic symptoms diminished; altogether improved. The injection was repeated several nights, the good effects apparent being the rapid induction of sleep, diminution of tendency to cough, general state of ease and tranquillity. Under a mercurial and iodide of potash course of treatment, together with blistering, the man made a good recovery. Without detracting from the beneficial action of the last named medicines, much of the good results obtained must, I think, be ascribed to the powerful tranquillising effect of the morphine hypodermically administered. One curious and, I think, noteworthy fact, in connection with this case, was, that for six months previous to present illness, Maher had quite lost the sense of smell; but subsequent to his recovery this became most acute, almost morbidly so. To what was this due? Had the course of mercury or that of the iodide of potash the credit of producing such a change?

CASES IN COUNTRY PRACTICE.

REMOVAL OF A LARGE NASO-PHARYNGEAL POLYPUS WITH WIRE ECRASEUR.—TALIPES VARUS SUCCESSFULLY OPERATED ON.

By Thomas Hayes, M.D. Edin., M.R.C.S. Eng.
Medical Officer, Shanagolden Dispensary.

J. O'Sullivan, æt. fourteen, the son of a labourer, strong and healthy looking, consulted me in the month of May in the present year. "About 2½ years ago he found his left nostril stopped, he could not breathe through it," it bled occasionally and sometimes considerably; latterly he found a great deal of trouble in breathing, a choking sensation and frequent vomiting; gradually he began to feel drowsy, and for some time before he came to me whenever he rested during the day he dropped off into a *snoring slumber*. His father told me "he was always asleep or going to sleep," which I believe was not a very exaggerated statement, as I found whenever he came to consult me and waited any time before being attended, he usually dropped off into a deep and stertorous sleep, reminding me of the peculiarity which Dickens attributed to Pickwick's fat boy, and which, until then, I regarded as the most extravagant flight of fancy on the part of the great and gifted novelist. He spoke with a very nasal utterance, as one suffering from a severe attack of inflammation of the fauces; his appetite was small, but he had no difficulty in swallowing. He consulted three doctors before coming to me: one said there was nothing wrong with him; the second was unable to decide what was his complaint; and the third advised him to go to Dublin to get a "chance of his life," as nothing could be done for him at home. He was recommended to me as a *dernier ressort*, by a gentleman of the county who entertained very faint hopes of a successful result for the poor boy. After having heard the history of the case, and having made a slight examination, I came to the conclusion that I had a polypus to deal with, but on carefully looking into the nares no trace of a polypus could be detected; yet the left nasal passage was occluded as no air could be driven through by a forced expiration; but I succeeded in injecting water through the nose into the pharynx. The right nasal passage was partially obstructed; on looking into the mouth the soft palate was seen depressed and convex resting on the tongue. I raised up the palate and tilted up the uvula, and looked into the fauces which presented nothing abnormal: but I did not succeed in getting a glimpse of the overlying tumour, which seemed to have stretched the curtain of the palate; but did not appear beyond its arches. I examined with the finger, and found the tumour pressing on the palate, but my exploration was not sufficiently exhaustive to ascertain its nature; for as soon as my finger extended beyond the arches of the palate, the boy got such a fit of suffocation and vomiting, that I was forced to desist. With a view to try and ascertain the situation and extent of the obstruction, and with a hope—should it prove to be a soft polypus—of detaching it or drawing it into the nasal fossa, I passed an elastic catheter, armed with a strong ligature, through the nasal cavity into the pharynx. There was some difficulty in getting the catheter past the obstruction, but it ultimately glided down by the *left side* of the pharynx, which lead me to believe that the tumour was attached more towards the mesial line than in the vicinity of the turbinated bones or fossa, the usual *habitat* of polypi. I brought the ligature forward through the mouth, attached a small plug of lint, and guided it over the palate as in plugging the posterior nares, and then drew it forward through the anterior nares. No result followed; the polypus was neither displaced nor detached, but I found the throat less sensitive to digital examination.

I again tried to pass my finger *over* the arch of the

palate, and I succeeded this time in ascertaining the nature and size of the tumour. I found it round, smooth, and hard, filling up the space between the posterior nares and the back of the pharynx, resting, with the intervention of the palate, on the dorsum of the tongue, occasionally dipping into the opening of the glottis, and producing spasmodic choking fits, which the father stated, so terrified himself, that he was unable to sleep at night for some time before the operation was performed, lest his son should die in one of them.

I determined on removing the tumour with Maw's wire écraseur for nasal polypi. I ordered the instrument, and in the meantime the tumour grew so much, that when he came to me on the 4th of July to have the operation performed, the tumour had grown so large, that it was only necessary to raise the uvula to see a smooth, whitish, rounded body, almost completely blocking up the breathing channel between the nares and larynx. I tried to ascertain its point of attachment by passing my finger about it, but the only thing I could ascertain was, that I could put the loop of wire over it, and so secure its being securely ligatured.

The Operation.—I passed a catheter, armed with a ligature, with some difficulty, through the nose into the fauces : I drew one end of the ligature out of the mouth, I withdrew the catheter, and with the ligature pulled the wire looped through the nose, and brought it forward into the mouth : I attached both ends of the wire to their proper place in the écraseur, moving the instrument into the nose. I stood behind the patient, and pressed with my fingers the loop of wire over and in front of the tumour. I kept my fingers on the tumour to prevent the wire slipping off, while my friend, Dr. Madigan, who gave me valuable assistance, turned the handle of the écraseur to tighten the noose and strangulate the tumour. After a little the wire came away, but the tumour was not detached ; I then came to the conclusion that the tumour grew from above, and not from the floor of the nose, as one would suppose from the catheter passing outside and behind it ; at all events, I felt sure that the loop should pass over *behind* the tumour. I passed the armed catheter again, and this time with two ligatures, to leave one in for an emergency—a very wise precaution as it proved. I pulled the wire through as before, passed the loop behind the tumour, kept the tops of both index fingers steadily on it, to prevent the loop passing over it. When the écraseur was worked, it was very soon evident that something was caught in the loop, at which the wire had some tough work ; the boy screamed as it tightened, but on the whole bore it very well without chloroform. After a few more turns of the handle of the écraseur, to my great discomfiture, the wire yielded to the resistance offered by the tumour—a coil of three wires broken by the roughness of a nasal polypus ! Who would suppose such a thing ? But I must say that the wire did not seem to me to be good, and the tumour was very firm. I then tried the strongest wire of the three sent with the instrument. The supplementary thread left in the nose was now of service (a double one was inserted) ; the loop of wire was pulled through and adjusted round the neck of the tumour ; the écraseur was worked as before. I kept my fingers on the tumour, which I found was fairly encircled this time, but I now wished to guard against its dropping into the pharynx, and causing suffocation. After a little, the wire came through the foramen of the écraseur. The tumour did not drop down on my fingers immediately ; I feared a failure after all—but hold ! I find it loose, ready to fall down. I pressed the head forwards, and never removed my fingers from beneath it until it dropped out of the boy's mouth on the floor. I gave a sigh of relief—of joy. What a glorious success due to French ingenuity ! I could have elevated Chassaignac to the seventh heavens, so effectual, so decisive was the success obtained by his charming invention. There was no hæmorrhage, except a slight oozing after passing the catheter. The patient has felt quite well since the operation. The drowsy symptoms presented in this case were, in my opinion, due to imperfect arterialisation of the blood, and not to any pressure from the nose on the base of the brain. The tumour proved to be a fibrous polypus. It was removed with as clean a cut as if done with the knife.

TALIPES VARUS.

Two cases of congenital talipes varus came under my observation within the past two years ; in each case only *one* foot was deformed—the right foot in one and the left in the other. Mr. Erichsen in his excellent work "On Surgery," which, as a student, I read carefully, says—"It is the most common form of congenital deformity, *both feet being found similarly affected*." Not in all cases according to my experience. Both the children were a year and nine months old, and limping about, when I performed the operation. I divided subcutaneously, with the tenotome knife, the tendos-achilles and also the plantar fascids which were contracted. I did not find it necessary to divide the tendons of the tibiales antici and postici. There was very little bleeding. I applied a small piece of lint over the wound, and embraced the foot and ankle with adhesive plaster ; applied a splint lined with cotton wadding and extending beyond the foot, which I kept quite straight, leaving as little angle as possible in front of the ankle. A roller kept the toes and foot well everted, embracing the limb and splint as high as the knee. I kept the foot in this position for a fortnight, occasionally adjusting the splint and bandage, A *home-made* Little's shoe was then applied. The cases turned out quite successful. I recently saw one of them, operated on a year and a half since, and he walks about without the least noticeable deformity. The other is equally successful, so his parents tell me.

I have followed the practice of Professor Spence, or Professor Dunsmure—I forget which, as I studied under both at Edinburgh—in putting up the foot *straight or extended*. If I rightly understand Mr. Erichsen, he recommends *the toes to be* "well drawn up, and supported by pegs attached to the splint." I prefer the Edinburgh practice, as it seems to me a better means of keeping the foot everted, and of allowing the tendo-achilles to unite, and when the child begins to walk, the pressure will turn up the toes, and give the foot its proper angle at the ankle.

THE INTRODUCTORY LECTURE

AT THE

MATER MISERICORDIÆ HOSPITAL,

WAS DELIVERED

ON THURSDAY, NOVEMBER 3RD, BY MR. HAYES,
One of the Surgeons.

MR. HAYES began his address by welcoming his audience, which included not only a large class of students, but also many friends and supporters of the institution. He next proceeded to advise and encourage those present who were about to commence to continue and, he hoped, largely prosecute the study and advancement of knowledge, which would enable them to alleviate human suffering, combat disease, and even prevent its development. He alluded to the various reasons which induce men to enter the ranks of Medicine, and stated that, happily, in his experience, the medical student, *of reality*, was far different from the character which fiction and misrepresentation had painted under that name.

The lecturer next described the surroundings necessary for the student of medicine, and dwelt upon the relationship which should exist between teacher and pupil, also how the latter ought to have the opportunity of studying under the master of his choice ; and, while condemning the system which favours an unnecessary number of teachers, and causes divided responsibility, yet he advo-

cated the demand for a full and efficient medical and surgical staff in *every* hospital open for clinical instruction. He added, that "one man, however able as a practitioner, cannot afford instruction of equal value in every branch of either medicine or surgery; and, again, the method of one master, which will answer admirably with some students, may serve only to confuse, mislead, or repel others." He then pointed out the great opportunities and advantages for professional study which exist at the Mater Misericordiæ Hospital, and how the students there, become even involuntary, impressed with, and are induced to copy, the respect and solicitude ever displayed towards the sick and injured. In speaking of the new portion of the building, where wards have been set apart for the reception of patients suffering from contagious diseases, Mr. Hayes drew attention to the fact that, heretofore, many poor patients were slow to enter some of the hospitals in the City because they feared the absence of kind, attentive friends, usually to be found at even the humblest bedside. No such objection could now be raised, as the good Sisters of Mercy, who labour for no earthly reward, count not time, trouble, or expense, when by such means they can "assuage pain, restore health, or smooth the path, lonely and awful, which leads to the world beyond the grave."

Mr. Hayes concluded his address in the following terms, —"Gentlemen, I thank you for your courteous attention; I am conscious that my observations have fallen as far short of the requirements of this occasion as of my own wishes. Throughout, my object has been to impress upon you how essential are the means towards the end in medical study. A youth may become a classical scholar in a hedge school, and possibly surpass at examination a university graduate; so a medical student, whose surroundings were deficient, or who neglected proper opportunities, *may*, perhaps, obtain a diploma, but he should never dare tamper with human life; yet, could we read the secrets of hearts I fear we might find that, even in medicine, instances are not wanting to illustrate how often 'fools rush in, where wise men fear to tread.'"

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XII.

PRECIPITATION OF SEWAGE WITH CAUSTIC LIME.

As far back as the beginning of the year 1802, M. Lewis James Armand Estienne obtained a patent for the use of lime as a means of disinfecting and consolidating human excrement; but it was not until the year 1844 that caustic lime was employed for the precipitation of sewage. In that year Dr. Clark, of Aberdeen, and Mr. John Graham, of Manchester, resorted to it for the purpose of purifying the refuse water from the Mayfield Print Works at Manchester, and the results were so satisfactory that the process was immediately adopted on a large scale. It was also used at that time for the purification of the River Medlock, which receives the sewage and trade refuse of Manchester, but although successful, the cost of the process was considered to be a hindrance to its adoption, for Dr. Clark was of opinion that it would require about a ton of lime daily to defæcate the whole of the water of the river. In the autumn of 1854, when the state of the river was so bad as to create alarm for the public safety, the process was again recommended by Dr. Crace Calvert, of Manchester, who found, from experiments made at the request of the Sanitary Association, that the black and fœtid water of the river could be completely purified, by adding to it from two to three grains of hydrate of lime per gallon of water, and allowing it to settle. Taking the average of five successive days' experiments, the following were the results :—

Constituents per gallon.	Original Water.	Effluent Water.
	Grains.	Grains.
Dissolved matters . . .	32·00	25·76
Organic matter . . .	8·54	3·50
Mineral ditto . . .	23·46	22·26
Oxygen required for oxydation	—	—
Matters in suspension . . .	6·65	0·00
Organic matter . . .	3·57	0·00
Mineral ditto . . .	3·08	0·00

From which it is evident that the lime precipitated not only the suspended matters, but also a large proportion of the dissolved organic matter, leaving only about three and a-half grains of this impurity in a gallon of the water. The precipitate was found to subside very rapidly, the supernatant water being perfectly clear, colourless, and inoffensive.

This method of treatment resulted from the patent obtained by Dr. Clark in 1841, for softening and purifying water for domestic purposes by means of caustic lime, it having been found that the flocculent precipitate thus produced removed from the water a notable quantity of dissolved organic matter, it being a property of such precipitates to aggregate and carry down not merely the suspended matters of foul water, but also a considerable amount of the dissolved impurities. This fact was more fully developed in the year 1846, when Mr. William Higgs obtained a patent for the treatment of sewage in subsiding tanks or reservoirs, by means of "chemical agents for the purpose of precipitating the solid animal and vegetable matters contained therein, hydrate of lime, commonly termed slack lime, being preferred;" and five years later a like patent was obtained by Mr. Thomas Wicksteed, who proposed to manufacture manure from sewage or other liquids containing fertilising matters, by mixing them with milk of lime, collecting the deposit, and submitting it to certain centrifugal drying machinery, "whereby the whole or nearly the whole of the moisture is driven off, and the manure or fertilising matter is obtained in a state commodious for transport." Both of these patents were put into operation on a large scale by the patentees, with considerable sanitary success, although the commercial results were not encouraging. At Tottenham, for example, where Mr. Higgs's process was tried, and at Leicester, where Mr. Wicksteed's was adopted, the whole of the sewage of the two places was submitted to treatment with lime, and the results were most satisfactory, as regards the purification of the sewage, and the marked improvement of the neighbouring streams into which the purified sewage was discharged. In fact, the Tottenham Local Board of Health were so pleased with the process, that in the early part of 1857 they published a testimonial to the effect that Mr. Higgs was treating in a most satisfactory manner the sewage of from thirty to forty miles of sewers, and dis-

charging the supernatant water in a comparatively pure state into the River Lea, so that the Board was thus enabled satisfactorily to sewer and drain their populous district, and dispose of the sewage without annoyance to anyone. At Leicester also, in 1858, three years after Mr. Wicksteed's works had been established, the River Soar had become changed from a most foul and pestilential stream into a comparatively pure river, for before the sewage was purified by Mr. Wicksteed's process the water of the river was black with decomposition, all the fish and aquatic plants had been killed, and persons exposed to its influence were constantly ill. At the Belgrave Mill, which is just below the point where the sewage enters the river, the foulness of the stream was such that in summer time the water of the mill-dam appeared to boil with putrefaction, and the stench was intolerable. So large, indeed, was the quantity of sulphuretted hydrogen evolved from the water that the silver in the men's pockets turned black in a few hours, and, as might be expected, those who worked at the mill were constantly affected with diarrhœa, and rapidly fell off in health; one man only, out of thirty, in eighteen years had been able to withstand the effects of the effluvium, and he it was who gave us an account of the matter. But soon after the lime process had been adopted the river presented an entirely different appearance, for aquatic plants had begun to flourish, the fish had returned, the black mud had ceased to accumulate, and the mill-dam was no longer offensive. All along the stream the people spoke of the change with satisfaction, for the process had evidently fulfilled the requirements of the Local Act of Parliament, which demands that the sewage water discharged into the river from the works shall not occasion a nuisance or be injurious to the health of those who live or are employed upon the banks of the stream.

At Tottenham, at the time of our visit in 1858, the sewage was dealt with in a comparatively fresh state, so that when it arrived at Mr. Higgs's works it was neither decomposed nor disintegrated. The average quantity of sewage amounted to about 175,000 gallons a day, and this was furnished by about 10,000 persons. On reaching the works it was first strained and then treated with twelve grains of lime, in a creamy condition, to every gallon of sewage, the amount of lime used per week being just one ton to 1,225,000 gallons of sewage, and the product of dry manure or precipitate thus obtained was from four to five times the weight of the lime used.

At Leicester the quality of the sewage was exactly similar to that of most large towns, except that it was often tinted with dye-stuffs, the solid matters being much disintegrated and far advanced in putrefactive decomposition. The population of Leicester, in 1858, was about 65,000, and the amount of sewage about 2,000,000 of gallons a day. The greater part of this was conducted to the works, and treated with lime—the proportions being from three to sixteen grains per gallon of sewage. In the summer, when in full work, the last named quantity was used; but in winter, when the process of putrefaction is checked by cold, the former proportion was employed; and the amount of dry, solid precipitate obtained was from three to four times the weight of the lime used. In fact, when twelve grains of lime were employed, as at the time of our visits to Leicester and Tottenham in 1858, the following were the amounts of organic and mineral matters precipitated from each gallon of sewage :—

Constituents per Gallon.	Leicester.		Tottenham.	
	Raw Sewage.	Effluent Water.	Raw Sewage.	Effluent Water.
	Grs.	Grs.	Grs.	Grs.
Dissolved Matters.	70·00	66·99	54·50	48·99
Organic ...	13·49	10·65	9·49	8·01

So that in the case of Leicester sewage the precipitate obtained from a gallon of sewage, with twelve grains of lime, amounted to nearly forty-two grains, of which about eight grains were organic matter; and in that of the Tottenham sewage it amounted to nearly sixty-five grains per gallon, of which about sixteen grains were organic. These results accord very closely with experiments made at that time in the laboratory with ordinary London sewage, and from which it was ascertained that with twelve grains of lime per gallon of sewage, from the several City sewers, the average amount of precipitate obtained was about 54·5 grains, of which 21·1 were organic. This consisted of all the suspended matters of the sewage, amounting to 38·2 grains, and about one-fourth of the dissolved organic matter, together with the lime which was converted into carbonate and phosphate. The particulars of these experiments are shown in the following table :—

Proportions of Organic and Mineral matters precipitated from a gallon of London Sewage with 12 Grains of Lime.

	55·74		38·15		54·45			

The flocculent precipitate which is thus formed settles at the rate of from one to two inches per minute, and in the course of an hour it subsides to about the fortieth part of the bulk of the original fluid, leaving a clear supernatant liquor, which is comparatively inoffensive, and which may be admitted into a running stream of good water without causing offence. In a sanitary point of view the careful precipitation of sewage with lime has undoubtedly been very successful, although it has not been found profitable commercially; for the precipate is chiefly composed of carbonate of lime and non-nitrogenous organic matter.

Hospital Reports.

THE SURGICAL HOME.

In a recent visit, one of our reporters was shown several interesting cases. Two patients had been operated on for fibrous tumour of the uterus, by the method, we believe, devised by Mr. Brown—*i.e.*, by incision of the os au cervix uteri by a hysterotome. In both cases the patients mentioned that they had lost very little blood by the operation; that the symptoms of uterine colic had quite disappeared, and that they were quite restored from the feelings of weight and uneasiness in the pelvic regions. He saw in the wards a young lady of the age of twenty-five, who, according to the statement of her friends, since the age of four had masturbated until two years ago. She had been subject to epileptic fits during the whole of this period, and had lost all her teeth during the paroxysms caused by epilepsy. She had been entirely imbecile, and had not been able to learn reading, writing, or counting. The habit was constant every evening on going to bed. Her friends, hearing of Mr. Brown's views, brought her to that gentleman, who removed the nymphæ and clitoris about eighteen months ago. Now the young lady is able to go about anywhere by herself, is quite cheerful, has learnt the multiplication table, and told us that 8 x 8 are 64. Has also learnt reading and writing during the past year. This case induced our reporter to ask for full particulars, which have been supplied as follows :—

"Epilepsy.—Miss —, æt. twenty. During the primary dentition, suffered from violent convulsions; after this she was well for a few years, when she began to suffer from epileptic fits. These, at first occasional, became gradually more frequent, and, on the establishment of the menstrual function, they became more frequent at these periods—often four or five fits in one day.

"Menstruation quite normal. In the fits she usually bit the tongue, until the front teeth were extracted. For the last ten years she has been almost continually under some treatment—allopathic, hydropathic, or homœopathic—but without the slightest benefit from either method, the severest and the mildest measures having been adopted. She was taken away from school, was placed under the constant care of an attendant, was not allowed to go to church, or even to walk out without holding the hand of her attendant. Her mind became enfeebled, so that she was unable to apply herself to reading, work, or amusement, and her expression was rapidly assuming an imbecile or idiotic cast. When spoken to, she would stare vacantly at you, or reply with hesitation, and was unable to sustain a conversation. Her complexion was pale, pasty; digestive system, however, in tolerable condition.

"*Examination.* — Long, flabby labia and clitoris—no hymen—evidence and confession of long peripheral irritation.

"*April 30th.*—Mr. Brown removed labia and clitoris, and divided a fissure of rectum in the usual way, and her hands were confined.

"*May 6th.* — Progressing favourably. Pot. bromide twenty grains, three times a day.

"*June 22nd.*—Nothing worthy of note until to-day, when menstruation appeared for the first time since operation. Patient considerably improved; hands still confined when in bed. She got about in the fourth week. Continue bromide.

"*July 28th.*—The last menstrual period was normal; again menstruating; continue bromide; progressive improvement.

"*October 30th.*—In this case, there has not been anything requiring frequent notes, and her progress may thus be summed up. For some two months she retained a good deal of childish or imbecile appearance, and the hesitation in conversation so characteristic. She became gradually weaned from the subject of irritation about the external genitals. At first cautiously, and then as a rule, she went out to walk and to church on Sundays, and finally took to reading, with profit, and learning new modes of fancy work, tatting, &c., gaining, at the same time, all the freshness of complexion and physical vigour of renewed health with the cheerfulness and vivacity of youth. She has lost all traces of her disease, and is in perfect health. The restraining of the hands has been continued, for after her mental restoration its object was explained, and she would not discontinue the use of the bandages. She goes home to-morrow, October 31st."

NORTH-LONDON CONSUMPTION HOSPITAL.

In a recent visit to this institution at Hampstead, we were pleased to see the really admirable position of the hospital as a hygienic establishment for the cure of consumption and other chronic diseases. This hospital was formerly a private house belonging to the celebrated artist, Stanfield, and is situated at Greenhill, Hampstead, about ten minutes' walk from the top of the hill. The wards are cheery and comfortable, with one exception, viz., of the male dormitory, which is in what formerly we presume was the studio, situated in a building of one story, in a wing of the house. The number of beds in the hospital is about thirty-six, but there are rarely more than thirty patients in the hospital. We strongly recommend the Committee, in case they decide on extending the number of beds, not to build a larger hospital, but rather to purchase a similar house in Hampstead, and thus avoid the mistake of large pestilential congregations of the sick and dying. We regretted to see that there is an out-patient department connected with the Hospital at Hampstead, as well as in Tottenham-court road. This seems to us a perfect waste of good money; what is wanted being beds for poor consumptives, not out-of-door medicines which they could get at any hospital or dispensary just as well. In the wards we remarked, under the care of Dr. C. R. Drysdale, two cases of alcoholic phthisis, in males aged thirty-one and thirty-three years, respectively. Dr D. thoroughly admits the doctrines of Dr. Andrew Clark and others, who maintain that there are several kinds of destruction of the lung comprehended under the name phthisis, which ought to be carefully kept n view. In tuberculosis in early life, or before the age of twenty-four, the majority of the cases are hereditary in his opinion, but after thirty a large number of cases of breaking down of the lung substance in males is traceable to alcoholic poisoning, and in females to bronchitis. Syphilis is the cause, occasionally, of cavities.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

General Meeting, Nov. 7, 1870.

John Gay, Esq., F.R.C.S., President, in the Chair.

Mr. John Daniell Hill exhibited a patient on whom he had performed primary excision of the knee. The young woman was on her way to the Royal Free Hospital to be

treated for fractured ribs, when she was thrown out of the cab and the knee-joint torn open to the extent of four inches. Mr. Hill sawed off the articular surfaces and removed the patella, there was protracted collapse after the operation, but at the end of from four to five months a sound union was effected.

Mr. Henry Smith said this case was highly important as showing that, though the rule in these cases was to amputate, yet excision might be successfully performed.

The President said that he thought mental depression had much to do with the want of success in primary excision of the joints. In military practice excision did much better than in civil.

Mr. Barnes asked Mr. Hill whether he would adopt excision in all cases of injury causing the opening of a joint.

Mr. Hill said yes, when the synovial membrane was torn as it was in this case. Mr. Hill then showed a patient, aged twenty-three, who had had an aneurism by anastomosis, 1¼ inches across, follow on a blow over the right temporal region. Mr. Hill tied the occipital temporal and posterior auricular arteries and acupressed some of the other vessels, eventually he had to ligature the mass and its sloughing out was followed by free hæmorrhage ; a complete cure had taken place.

Mr. Spencer Watson had seen this case before operation, and congratulated Mr. Hill in having so ably overcome the difficulties presented.

Mr. Henry Smith wished to contradict a report he had heard to the effect that he had given up the practice of puncture for swelled testicle. Far from this being the case the operation was now in greater favour than ever with him, and he believed he could record about 500 cases in which he had thus operated during the last five years, the immediate relief that resulted from the operation seemed due to relief of the tunica albugenia from tension.

Mr. Barnes said he had had a case under his care where the operation of puncture done sometime previously, seemed to have led to much pain and irritation on account of which the patient applied to Mr. Barnes.

Mr. Royes Bell had seen a jet of serum spirt out, on puncturing an inflamed testis, immediate relief followed. Mr. Bell thought very highly of the operation.

Mr. Bonney inquired as to the length of the incision required.

Mr. Adams asked Mr. Smith if he had tried subcutaneous division of the tunica albugenia, operating thus no blood would be lost, and it would be proved whether it was the loss of blood or the division of the tense structures that gave relief.

Mr. Smith said that at present a mere puncture was enough, but he would remember the suggestion of Mr. Adams.

Dr. Sansom then read the paper of the evening

ON THE CORRELATION OF PUTREFACTION, FERMENTATION AND MORBID INFECTION.

The paper embodied the following propositions : 1. Putrefaction and fermentation are each due to the influence of living, growing, and multiplying material particles. *A.* Fermentation is the result of the vital acts of particles of vegetable protoplasm in an organic fluid of uniform composition, the particles assuming distinct morphological forms according to the nature of the fluid. *B.* Putrefaction is due to like influences exerted upon organic matter of a more complex or mixed kind. 2. The atmosphere contains minute spores, ova, and particles of protoplasm, which it wafts from place to place. These are, for the most part, perfectly harmless. 3. The diseases of infection are due to minute particles of living protoplasm which are transmitted by physical intermedia are capable of reproduction within the recipient organism and are excreted in vastly increased numbers. 4. The infecting molecules differ in their potentiality pathologically as other living molecules differ in their potentiality physiologically, so special poisons induce special diseases. 5. Such molecules present complex reactions of living beings, and though they resist certain physical influences, they are destructible by others. Thus, though they may be desiccated and yet in the presence of moisture assume vitality ; yet slight chemical or physical disturbance may destroy them. 6. Fermentation and infection are alike due to living molecules, but though it is possible that in some cases (cholera, typhoid), the molecules of fermentation in complex conditions can induce infection, it is far from proved that all the diseases of infection are due to the organisms of fermentation.

Dr. Richardson thought Dr. Sansom had made as able a defence of his point as could be expected, he alluded to the different effects of oxygen gas on matters according to its different state. Liebig has shown that oxygen is not essential to decomposition, save as it results from the decomposing compound. Experiments made years ago by Dr. Barker, of Bedford, confirmed those of Dr. Parkes quoted by Dr. Sansom, that sewer emanations inhaled do not appear to cause any specific disease. Fifteen years ago Dr. Richardson had shown before the Epidemiological Society that colloidal organic poisons were soluble only under certain conditions. The advocates of the germ theory had been reducing the so-called germ further and further as the capabilities of their microscopes improved, and what they would eventually come to regard as a germ none could tell.

CLINICAL SOCIETY OF LONDON.

Session 1870.

1st Meeting Oct. 14th.

Mr. Paget, President, in the Chair.

There was no Introductory Address at the opening of this the fourth session of the Society on the 14th Oct.

Mr. Spencer Watson read the "Reports of Four Cases of Parenchymatous Keratitis, associated with Acute Rheumatism." The patients were young adults, all under nineteen years of age. Both corneæ were affected, and the symptoms and appearances were not distinguishable from those of parenchymatous keratitis due to inherited syphilis. Out of a series of cases, extending over the last ten years, Mr. Watson had only observed acute rheumatism in association with parenchymatous keratitis in these four ; but he suggested that in some others of the series this complication may have itself cut short the observations, by preventing the attendance of the patients at the Ophthalmic Hospital. From these cases it was conjectured that the interstitial keratitis of inherited syphilis may be allied to rheumatic inflammation, and may possibly yield to treatment such as is beneficial in the latter disease. Two of the patients, whose cases were related, were exhibited to the Society. In one the attack of keratitis had occurred eight years ago. It was found in this case that the young woman had become myopic since, and most probably in consequence of the attack.

Dr. John Harley read a paper on "Injury to the Liver resulting in Abscess ; rupture on the 14th day, diffuse peritonitis ; formation of a second abscess opening into the colon on the 25th day ; interrupted discharge of pus by the large intestine until the 112th day ; and complete recovery." The patient, aged sixty-nine, was, by the fall of his horse, thrown forwards upon the brass turrets of his horse's pad, thus bruising the epigastric region. An inflammatory tumour, exquisitely painful, formed just above and to the *right* of the umbilicus. On moving in bed this suddenly disappeared, followed by collapse, and subsequently general peritonitis. In a few days the peritonitis became circumscribed, and the pain and swelling limited to the *left* side of the umbilical region, where there was evidence of the formation of a second abscess. This also suddenly disappeared, with dangerous collapse and the evacuation of pus by the rectum. Marked colic symptoms, showing lesion of the bowel, preceded this second rupture. From time to time there was retention of the purulent discharge and hectic, but ultimately a free passage was maintained, the appetite returned, and the patient made so complete a recovery that, at the end of seven months from the time of the accident, he was able to ride and follow his professional work, and he has since (for the last eighteen months) enjoyed perfect health. The author considered that the left lobe of the liver was bruised or lacerated by the accident; that an abscess formed which pointed partly towards the right hypochondrium and partly within the small omental sac behind the stomach ; that rupture occurred in the latter situation, the pus escaping into the small omental sac, and then, finding its way through the upper layer of the transverse meso-colon, passed further downwards

between its layers, forming a second abscess by the side of the descending colon. This, in its turn, caused inflammation and rupture of the contiguous wall of the large intestine, and thus the pus was liberated and carried out of the body. Hectic and jaundice attended the retention of the discharge.

Dr. Ogle read a case of Tetanus. The patient, a healthy boy, got a bruise on the thumb. Three days afterwards he complained of stiff-neck, and vomited, and shortly afterwards became affected by opisthotonos. On the fifth day after the injury he was admitted into St. George's Hospital in a state of tetanus. He was put fully under the influence of belladonna; ice was constantly kept applied to the spine, and chloral was given at night to induce sleep. It was noticed that at no time did the sardonic smile exist, and there was never any trismus or (except on one day) difficulty in swallowing liquid food, such as wine, brandy, beef tea, and beaten-up eggs. In this case the temperature and pulse were registered twice a day; and it was noticeable that almost throughout the patient's stay in the hospital the temperature was higher in the evening than in the morning, on one day reaching 102·3 deg. About the fourteenth day after the injury the tetanic symptoms began to abate, and by degrees the belladonna and the chloral were discontinued, and also the application of ice to the spine. After about a month from the accident the patient left the hospital quite well, and has so continued ever since. Dr. Ogle suggested that possibly the examination of numbers of cases of tetanus might show that the temperature always increased in the evening, and that this fact might have value in diagnosing true tetanus from certain cases of affections of the spinal cord and its membranes, certain cases of hysteria, and strychnia and other poisoning. Dr. Ogle believed that the highest temperature arrived at in tetanus was recorded by Wunderlich, who described it as being 108 deg., shortly before death; 112·55 deg., at death; and 113·56 deg., after death. He also alluded to a case of tetanus in which, after the attack, the patient was subject to great irregularity of the heart's action, with much discomfort and palpitation on exertion, as if the mechanism of the organ had been injured in some violent muscular effort.

Mr. Croft divided tetanus into two classes: one in which patients died, and the other in which they recovered. He professed scepticism as to the use of belladonna, but remarked, had treated cases with the hydrate of chloral with apparently good effect.

Dr. Harley required evidence as to the irregularity of the heart's action in the case related by the author; and attributed the favourable results of the belladonna treatment to the toxic effects of that drug.

Mr. Chunder Roy continued the discussion by saying that, according to experiences gleaned at Calcutta, he had come to the conclusion that in cases of tetanus death always occurred if the muscles of deglutition were affected; but in the absence of this symptom, the prognosis might be favourable; that, in consequence, symptoms only were treated; that Indian hemp and opium smoking were most commonly used (the latter not, in these cases, producing constipation), and that the general result proved the opium treatment to be the best.

Dr. Barclay quoted Dr. Fuller as to the advantage of belladonna in the treatment of cases of chorea, and said that with children it might be given advantageously in very large doses.

The Chairman recapitulated his experience as to cases of tetanus, the gist of which was that all drugs hitherto exhibited produced little or no appreciable effect. Of the cases which resulted in recovery, one was that of a boy in which nothing was done, another in which oxygen gas was employed continuously, and two others in which chloroform and other drugs were used. He also made some remarks as to treatment by Calabar bean, which were challenged by Dr. Anstie.

Further observations were made by Dr. Broadbent and Mr. Croft; and Dr. Ogle closed the discussion by explaining his own ideas as to the physiological action of belladonna in cases of the kind under discussion.

Second Meeting, Oct. 25th.

Dr. Sutton read particulars of two cases of Acute Scurvy, which were fatal, the one in twenty-eight, the other in fourteen days, and which had both originated in this country. Both patients were females, and in each instance vaginal hæmorrhage ushered in the disease. One, aged twenty, had tramped from the North, and been much exposed to cold and fatigue. Three weeks before admission into the London Hospital she had suffered from pain in the back and febrile symptoms, which were followed by a condition of the throat, which suggested diphtheria, except that the grey-looking membrane in the tonsils when peeled off was not renewed. The gums then became swollen, bleeding and sloughing, the bowels much relaxed, and death took place by collapse. At the autopsy sanguineous extravasations were found in the pleura, pericardium, kidney, stomach, and intestines, beneath the pia mater, and in the mucous membrane of the cheek. The second case was thirty-two years of age, and had lived at Bromley. Her illness had commenced fourteen days before admission with pain in the abdomen, and loss of appetite, headache, nausea, and thirst, followed by swelling of face and sanguineous spots in the skin over the chest and extremities. At the autopsy the gums were found sloughing; there were extravasations of blood in various parts of the body, and very characteristic scorbutic ulcers of the large intestine. Unfortunately it had been impossible to ascertain the diet upon which the patients had been living.

Mr. Harry Leach asked particulars as to the plan of treatment pursued in both cases. In a somewhat extended experience of scurvy on board the *Dreadnought* Hospital-ship he had failed to discover albumen in the urine, and would, therefore, suggest whether the first case cited (having regard to the fact that albumen was present, and that the kidneys were abnormally large) could be fairly classed as one of scurvy, pure and simple. It was a matter of regret that Dr. Sutton had been unable to collect any precise particulars as to the history of these cases, scurvy being mainly, if not wholly, dependent on the kind of diet taken.

Mr. Brudenell Carter thought scurvy in some cases was due not so much to the diet taken as to a certain want of power of assimilation of food on the part of the patient.

Dr. Buzzard observed that chronic scurvy, not very severe in character, was not uncommon in England at the present day; but in order to account for the rapidly fatal termination in these cases, he thought the intercurrence of some other disease, derived from a morbid poison, must be assumed, and the high temperature which had been noted tended to confirm this supposition.

Dr. Broadbent mentioned two cases that had come under his notice, similar in some respects to those of Dr. Sutton, one of which died in three weeks, and the other recovered. He particularly emphasised cold, wet, and exposure as chief exciting causes of scurvy.

Dr. Wiltshire remarked that in females the scorbutic state caused hæmorrhage into the pelvis, which was usually sub-peritoneal.

Dr. Greenhow gave particulars of some severe cases landed at Leith, from Greenland, some years ago, and two cases that had occurred in his own practice, both plainly due to abstinence from vegetable diet. He failed to recognise in Dr. Sutton's cases the marked symptoms commonly spoken of as indicative of scurvy.

Mr. Cooper Forster had seen, when attending the practice of the *Dreadnought* Hospital-ship, a great many very severe cases of scurvy. He also thought that two or three leading symptoms were, in the cases read, conspicuous by their absence; and asked the author if, in his patients, any contraction of the muscles about the popliteal space, or pain and tenderness about the knee and calf, existed.

Mr. Harry Leach remarked that these, though very usual, were not, strictly speaking, universal symptoms among patients admitted into the Seamen's Hospital with scurvy.

The President said that the observations of Mr. Forster, Dr. Greenhow, and Mr. Leach were worthy of special consideration; and having been informed just now by Dr. Buzzard that the production of scurvy in most cases involved abstinence from vegetable diet for some two or three months, he informed the Society that, some time ago, the entire omission of vegetable diet produced blotches on his own skin, of a markedly scorbutic character, in fourteen days. In noticing the remarkably anti-scorbutic properties of milk, he cited the case of a medical practitioner who lived exclusively on milk and arrowroot, and showed no symp-

toms of scurvy until after the lapse of ten or twelve years, convalescing rapidly after change of diet.

Dr. SUTTON, in replying, said that the albumen and the vaginal discharge were probably connected; that, with reference to previous history, the patients had merely remarked that they were badly off for food; that he had not observed any contraction or pain about the lower limbs, and that though unable to say positively as to whether or not these were genuine cases of scurvy, he had rested his diagnosis chiefly on the pathological conditions exhibited, more particularly with reference to the intestines.

Mr. BRUDENELL CARTER described three cases of Optic Neuritis. In the first case the patient was a young woman, apparently in good health, and the right eye only was affected. Its vision was reduced to qualitative perception of light; and an active mercurial treatment was employed, under the suspicion, which could not be substantiated, that the disease was syphilitic. Speedy recovery took place, and normal central vision was restored; but in one direction there was remaining effusion, and a corresponding blind spot in the field, at the date of the paper. The second case was that of a woman, thirty years of age, who became blind in a few days when in the eighth month of her eighth pregnancy. After delivery her sight began to return; and three weeks after, when she came to the hospital, she could read No. 20 of Jaeger with the left, and No. 16 with the right. At that time there was well-marked optic neuritis in both, with scattered patches of effusion in the choroid. Iron and iodide of potassium were given, and the right eye slowly improved, so that it can now read No. 2, the left remaining almost stationary. Both in the optic discs and in the choroid extensive atrophic changes had taken place. The subject of the third case was a boy eight years old, who fell from the roof of a shed to the ground. Shortly afterwards his left eye began to protrude, and became perfectly blind, while he suffered from severe pain in the head and from sleeplessness. The ophthalmoscope discovered optic neuritis. Treated by iodide of potassium and iron, with chloral hydrate at night, the pain disappeared, and the eye returned to its natural position in the orbit; but the neuritis passed into total atrophy, and not even perception of light returned, the other eye remaining unaffected. In a few observations upon these cases, the author referred to the fact, first noticed by Dr. Hughlings Jackson, that a considerable degree of optic neuritis may be present in certain cerebral affections without impairment of vision. The cases related seemed to show that, besides a traumatic neuritis and a well-known form produced by intra-cranial tumours, there was probably some constitutional state or diathesis with which optic neuritis is associated, as iritis is associated with rheumatism and syphilis. The discovery of such an association, if it exists, would be greatly promoted by the study of those slighter cases that may be found if looked for, but that do not come to ophthalmic surgeons because they do not, in the first instance, affect vision. The author urged physicians generally to lend their aid in investigating the causes of the affection, in order that its serious form might be successfully treated.

Dr. HUGHLINGS JACKSON, as a physician, was glad that an ophthalmic surgeon had drawn attention to the important clinical fact that extremely abnormal ophthalmoscopical appearances may exist when the patient can read the smallest type—viz., brilliant type—and when he considers his sight to be quite good. It is most desirable that ophthalmoscopical examinations should be made in cases of disease of the nervous system, whether the patient complains of defect of sight or not. At all events, the ophthalmoscope should be used when there is severe pain in the head, perhaps urgent vomiting as well, and certainly if there be also epileptiform seizures. The cases Mr. Carter had related were of great interest, especially those of unilocular neuritis. In physician's practice optic neuritis is almost invariably double. Dr. Jackson thought it a significant fact that double optic neuritis may occur from disease of but one cerebral hemisphere. With regard to Mr. Carter's remarks on the necessity of investigating the various pathological conditions of the optic nerves in cerebral diseases, Dr. Jackson suggested that a most fruitful field of work would be found in the observation of cases of double optic neuritis, complicated with certain epileptiform seizures, beginning unilaterally. In these cases we can roughly localise the disease causing the two symptoms, and in most of these there is evidence of syphilis.

Mr. CALLENDER could not pass without noticing the remark made by Dr. Jackson to the effect that it might be observed that injury to one hemisphere produced effects in both eyes, just as injury to one hemisphere abolished the faculty of speech. It reminded him of the difficulty which stood in the way of accepting such statements by reason of our want of knowledge of the relations which exist between various parts of the great nerve centres. With reference to the question of affections of the organs of sight, we should begin by clearly ascertaining the anatomical relations of the optic lobes in the formation of the fœtal brain. His observations on its growth showed that at the twelfth week the optic masses grew out from the upper sides of the middle cerebral vesicles, just as the olfactory lobes grow out from the lower sides of the anterior vesicle; that they had no connexion with the optic thalami, nor yet with the masses of fibres which unfold through the corpus striatum of either side to form the mantles or hemispheres. Thus it would be difficult, from an anatomical point of view, to associate affections of the organs of vision with disturbance of any of these structures. If injury or disease of nerve structure was to be connected with the occurrence of optic neuritis, it should rather be looked for in the tissues of the upper part of the corpora quadrigemina, or in that curious reduplication of the hinder wall of the posterior cerebral vesicle which is known as the cerebellum.

Dr. LIEBREICH closed the evening by exhibiting a fixed Ophthalmoscope, similar to that invented by this physician some sixteen years ago, but with recent mechanical modifications, and illustrated its working. He prefaced the illustration by saying, "Vous verrez dans ce cas tous ces details du fond de l'œil normal dont l'observation toujours répétée offre encore de l'interêt, même pour ceux qui ont déjà une grande habitude de poser le diagnostic des altérations pathologiques de ces parties. En effet, l'aspect du fond présente à l'état normal, on pourrait dire, autant de variations qn la figure humaine, et il faut l'étudier indéfiniment si on ne veut pas être exposé à prendre quelquefois pour une altération pathologique ce qui n'est qu'une modification individuelle d'un œil sain. Dans notre cas vous voyez le fond de l'œil d'un rouge clair, la choroïde étant faiblement pigmentèe. Au pourtour du disque optique seulement cette pigmentation est plus forte, et c'est à cause de cela que vous verrez ici très distinctement se reflet grisâtre de la rétine, qui s'aperçoit d'autant plus facilement que le fond est plus foncé. Car la faible quantité de lumière réfléchie par la substance de la rétine n'est visible que quand elle n'est pas trop effacée par l'eclairage plus fort de la choroïde. Sur la papille vous distinguerez facilement les veines plus foncées et plus larges, des artères, qui se caractérisent par un reflet jaune au milieu, et vous apercevrez au point d'émergence des veines le phénomène si curieux du pouls veneux qui, spontané dans ce cas, peut-être produit artificiellement par une très légère pression rhythmique qu'on exerce avec le doigt sur le globe. Poir voir le pouls artériel il faut exercer une pression plus forte et continuée, expérience qui n'est pas sans danger, une cécité complete pouvant devenir la conséquence d'une interruption artificielle de la circulation de la rétine. L'artère centrale de la rétine n'appartient pas à la classse des vaisseaux dans lesquels le pouls est visible, et le phénomène tout-à-fait pathologique, auquel on a donné le nom du pouls de l'artère centrale de la rétine, n'a qu'un rapport très indirecte avec la pulsation ordinaire du système artériel. Il dépend d'une exagération de la pression intraoculaire telle que nous le trouvons dan les cas de glaucome, et il dépend de ce que la vague du sang artériel ne peut entrer dan la partie trop comprimée de ces vaisseaux que par lo choc rhythmique durant le moment de la plus grande force du mouvement diastolique."

Death of Dr. Thomas Anderson.—The death is announced of this well-known botanist and Indian Surgeon, and for some years director of the Royal Botanic Gardens, Calcutta.

Bequests to Medical Charities.—Miss Eleanora Atherton, whose will was proved on the 3rd ult., under the enormous personalty of £400,000 has left besides large bequests to religious bodies and others the following:—£1,000 to St. Mary's Hospital, Manchester, £1,000 to the Manchester Royal Infirmary, and £500 to each of the following:—Manchester Eye Infirmary, Deaf and Dumb Institute, Earlswood Asylum for Idiots, Royal Hospital for Incurables.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 16, 1870.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

The returns of the Registrar-General are always full of interest to those whose knowledge of the theory of social science enables them to study such tables with profit. Unfortunately, the gentlemen at present presiding over the Registrar's department, seem to have but slight acquaintanceship with the writings of the *masters*, and, hence, the Reports are disgraced by a good deal of drivelling about the "natural increase of the population," and other foolish expressions: besides being occasionally used as the vehicle for expressions of silly glorification of the English race and other well-known kinds of twaddle. We have before us the quarterly return of the births and deaths, which occurred during the months of July, August, and September, 1870, from which we observe, that there were *registered* in the United Kingdom the births of 255,136 children, and the deaths of 159,102 persons in three months, thus giving an increase of population (leaving emigration for the moment out of the account), of 96,034. It appears that the resident population of the British Islands is probably at present 30,838,210 thus divided—England and Wales 22,090,163; Ireland, 5,525,210; and Scotland, 3,222,837. The death-rate for the quarter is 22·1 per thousand. The writer of the Reports is haunted with the idea that a rapid increase of population is an unmixed blessing: and thus we find, that he observes, that "the returns of marriages and births are satisfactory" (to himself). "The births in the summer exceeded the average." Some persons wish that they did not: but the Registrar-General is none of these.

Of English emigrants, 30,548 sailed from Government ports; 7,311 of Scotch birth quitted these shores; and 16,563 Irish expatriated themselves during these three months. The great bulk of all these abandoned the government of Great Britain and became citizens of the Western Republic. During the two last summers the emigration has been higher than in any previous summer since 1854; and we are not surprised to hear this, when we remember the over-population and poverty we have seen in London and elsewhere recently. The Registrar-General calculates that the actual increase of England was 40,000 persons in the quarter. Also, 13,438 foreigners emigrated from British ports, chiefly to the United States. Thus, about 55,000 of our fellow countrymen, women and children in three months of one year have been forced, chiefly through poverty we may be sure, to leave the shores of Old England, Ireland, and Scotland. In passing, we may remark that in a whole year not more than three or four thousand French people would have been forced by necessity to leave their "beautiful France." Probably, during the year 1870, more than 160,000 emigrants will be found to have been expelled from home and family by our habits of rapid multiplication, so advised by the *Times* and other organs of the land-owning classes.

The price of food does not seem to have been extraordinary high during the quarter cited. Wheat averaged 50s. 4d. a quarter. Beef, by the carcass, was sixpence a pound in the London Meat Market, and mutton 6¾d. a pound. The returns of pauperism still continue a disgrace to the civilisation of this country. In the three months, ending 30th September last, no less than 138,444 persons were in the receipt of in-door relief, and 787,976 of out-door relief. As a consequence of such a state of misery, destitution, and over-population, we are, of course, prepared to hear that the death rate, in many of our large cities, has been excessive. Thus, the mortality in the twenty great towns in the United Kingdom, including London, was at the rate of 25·3; it exceeded 30 in Bristol, Leicester, Liverpool, Bradford, and Leeds. These are the places in which chiefly our poorer neighbours are sacrificed to the Moloch of rapid multiplication. Compare the death rate of Liverpool, above 30, to that of a rural county such as Berwickshire, with a death rate of about 15, and we see how Nature plys her deadly plan of equalising population with capital. Compare, again, the total increase of the British Islands in ten years, from 1860 to 1870, namely, from about 30,000,000 to 30,900,000, with that of the United States in the same time, namely, from about 30,000,000 to about 42,000,000, and with that of France, which has remained about stationary, and we at once see how easily the great law of population may be verified, *i.e.*, that the race we belong to tends, when well fed and clothed, to double in from 20 to 30 years. We shall also understand how it is that when one epidemic disappears another appears, whenever over-population has lowered wages sufficiently to make the poorest classes live in poor lodgings, and without sufficient food and clothing. The two epidemics which have acted most murderously recently have been scarlet fever, which caused 7,498 deaths in the quarter, and diarrhœa, which caused 17,647 deaths. The scarcity of water was unfavourable to health this autumn; the sewage was too concentrated, and cleanliness was less observed than usual. It is now agreed that sewage should not be thrown into rivers, but restored to the earth by the dry or wet method. How to accomplish this is the rub.

There are some good remarks in the Report on the urgent necessity for providing improved dwellings for the working classes, and for demolishing fever dens. The writer truly observes, that when so much money is being spent abroad on human destruction, we at home ought not to grudge funds for experiments directed towards the

social and hygienic regeneration of our poorer classes. We should endeavour to "conquer the standing armies of disease and death, works of vaster amplitude and greater difficulty than the capture of cities, the subjugation of nations, and the destruction of armies." Alas! that the writer should be such a poor political economist, and yet have so good a heart. He is a rooted opponent of the doctrines of Malthus and Mill, and those who propose limitation of families, as the French do, for such evils; and yet he shows us how one pestilence, during the last thirty-three years, has been got rid of, only to be succeeded by another "check to population," in this endorsing unconsciously the very expressions of the discoverer of the law of population. "How difficult it is," he exclaims, "to quench the pestilences that afflict mankind is evident from a retrospect of the English returns, now extending over thirty-three years. Disease is no sooner extinguished in one form than it breaks out in another, and the increase of industry, by which the means of living are created, itself developes new dangers in the mine, in the close workshop, and in the crowded city."

We know that we shall probably speak in vain; and yet we cannot help saying, as we conclude this analysis, that if Dr. Farr and his able and conscientious colleagues would only study the works of the classical writers on political economy, including Chalmers, Senior, Garnier, and Whately, they might yet make their quarterly returns not only vastly more logical, but, in addition to this, they might, by continual reiteration of good and sound doctrines concerning population, accustom the thoughtless masses of mankind to see that low death-rates are incompatible with high rates of multiplication of families, and that prudence is the providence of the poor.

LIFE INSURANCE.—III.

It is an impartially useful exercise to continue, and carry as far as existing means enable us, a fair comparison between the British and American offices as they are affected by the laws of the Governments within whose spheres respectively they conduct their business. It has been already shown that the one great improvement which is needed with respect to the law on the subject in the great Republic is, that it should be taken out of the hands of State legislation, and that a National Department should be formed with uniform laws for the whole country. The law in the Empire State of New York, to which State the principal stranger candidate for our confidence belongs, is, as a law, everything that a law of the kind could be desired to be. But what is good for a part, and for a part so principal and so important, must be alike good for the whole; and, since the division of the whole Commonwealth into so many states or territories has been ordained for purposes in which the mere act of assuring men's lives has no special place or relation, it is obviously desirable that the law respecting companies formed for that end should be the same in all parts of the federation. For the circumstance of the New York Mutual Office being in the City and State whose name it bears does not confine its transactions within the limits of City or even State, but leaves it at no less liberty to accept lives from the Far West or the extreme South than from the precincts of Wall street and Broadway, or from the banks of the Hudson.

Our own new Act, which, so far as it is directed against actual fraud, cannot but prove highly advantageous, is not, however, without its defects. The deposit of twenty thousand pounds, besides being called for from companies formed after the passing of the law, and not from companies previously in existence, is to be allowed to be withdrawn so soon as the declared assets shall appear to amount to a certain sum. Now, if it is considered desirable, as we have reason to know it is, that an American office, like the "New York," for example, of such long standing and showing such satisfactory figures, should make a good round deposit, why should even an old office of British growth be exempt from a condition which the Act, after all, lays down as a general principle of safety for the public? What is aimed at is a material guarantee, and, if that is exacted from one, it ought to be made binding upon all, and upon natives no less than foreigners.

Not only would the money so deposited bear interest, but, in the hands of agents who understand their business, the fact would be converted into a powerful and persuasive argument in prevailing upon the hesitating, the reluctant, and the timorous, to avail themselves of the incomparable advantages held out by a well-managed and successful Life Insurance Company. But perhaps the greatest defect with which Mr. Cave's Act is chargeable relates to the valuation of Companies' liabilities under their outstanding policies. The officers are allowed to make their own valuations, and to make them, not yearly, but at longer intervals; to make them, too, on such basis as they please, provided only that they state what that basis is. Now, surely, a perfect law for the purpose would require the valuation to be made on three conditions: firstly, once a year*; secondly, upon a uniform basis fixed by law; thirdly, by a disinterested person. Such, at any rate, are the provisions of the American law, of which, we are bound to say, our own, so far as it at present goes, is but a very indifferent, not to say bad, copy.

In one respect, however, the English law may be considered as better than the American practice. Mr. Cave's Act requires, very properly, that every company shall send a printed copy of its financial statement to each one of the policy-holders under it. In the United States this is not done. But, though the policy-holders in that country have not the satisfaction of receiving such information through the post at their own firesides, yet the end of public satisfaction is generally answered by the wide-spread and easily accessible abstracts of the whole report of the Insurance Commissioners. Upon the whole, therefore, it is not too much to say that American insurers have better protection than ourselves. The Act of last session is a step in the right direction, but not much more than a step. A year or two's experience of its working will suffice to show its deterring effect upon dishonest enterprise and its discovering effect upon such persons as avoid the light. There are many English, and, comparatively, more Scotch offices, entitled to rank in the first class; and, with respect to others of either sort that are younger or smaller in dimensions and success, let their conductors be assured that they cannot show a better title to be admitted into the first class, or one

* Professor De Morgan says, respecting this point, "The valuation should be made yearly. It is absolutely necessary to any system which gives the real amount of their premiums to the insured."

which will sooner incline the public to admit them to that grade, than by being forward to give to the country at large, and to their own constituents and clients in particular, the fullest, clearest, and truest information of their state and progress. When the real nature and effect of the American law comes to be understood by us, we shall have the New York Life Insurance Company doing such a business, that the native offices will see the wisdom of asking for a state of law in this country as good as that which prevails in America, and as much better as honesty, ingenuity, and public spirit can make it.

Notes on Current Topics.

The Irish Conference on the Medical Act.

The Conference of Irish Licensing bodies assembled at the request of the King and Queen's College of Physicians, for the purpose of debating the anticipated legislation on medical matters, has held, since we announced its formation the week before last, two meeetings.

The delegates sent by each of the Licensing bodies were the following :—For the University of Dublin, Dr. Hart, F.T.C.D., Professor Apjohn and Professor Stokes ; for the Queen's University, Mr. Robert Rane, Dr. MacCormac, and Sir Dominic Corrigan; for the Royal College of Surgeons, the President, Dr. Albert Walsh, the Vice-president, Dr. Wharton, and Dr. MacNamara. The Apothecaries' Company was not represented, the conference being called of delegates from "bodies qualified to confer degrees or licences in medicine or surgery in Ireland," under which designation the College of Physicians did not consider that the Apothecaries' Company was included.

We are informed that a lengthened statement was made by Sir Dominic Corrigan, in the course of which he submitted to the Conference the main provision of the Bill, which embodies his views. The peculiar features of the measure were—Firstly : That the Licensing powers should remain as at present, in the hands of existing Corporations. Secondly : That no person should be placed on the Registry except on the production of qualifications both in medicine and surgery. Thirdly : That the proposed State examination should be compulsory only on candidates for public appointments.

The Conference has, we understand, proceeded to the discussion of the several questions raised in Sir Dominic Corrigan's scheme, and has already dealt with that of direct representation of the Profession in the Medical Council, respecting which, despite a strong adverse feeling on the part of some of the delegates, the general sense of the meeting was considered to be favourable.

About the War and Wounded

Dr. Marion Sims has let a little light into the hospital management at Sedan. The ignorance of some officials seems to have been astounding. The building is about 300 feet in length, by 66 in width ; it is two storeys high, and holds seven wards on the upper floor, and nine on the lower. These wards average 66 by 24 ft., and are 10 ft. high, and there was only about 600 cubic feet of air per bed ; yet it seems that a Committee of French Surgeons, on entering the hospital, wanted the windows to be shut while Dr. Sims and his colleagues were in dread of hospitalism and pyæmia, as well they might be. A little later we find the Prussians forcing the staff to receive cases of dysentery, diarrhœa, and typhoid. A sad mortality was the result of this, and many also died of pyæmia. We think the Prussian authorities acted disgracefully in this as in many other instances that have been brought under our notice. The Germans appear, throughout the war, to have provided for the wounded in a manner that reflects strongly on a civilized community.

***

Drs. C. Orton and W. D. Spanton have published, in a contemporary, an account of what they saw in a recent visit to the Seat of War. They say that after the battle of Sedan 14,000 wounded French were brought in. The stench was so horrible in some parts of the town that they suggested the propriety of having numerous peat fires kept burning all over the district. They were told of wounded lying on the field four or five days, and then remaining under tents untended for two days more. Of those whose injuries dated back a week, scarcely one recovered. They were told that all the operations in one ambulance were performed by one surgeon, although fifteen others were attached. This seems very strange.

***

At the Pathological Society of London Dr. Duncan showed portions of a watch that had been extracted from the fleshy part of a soldier's hip twenty-one days after a bullet had carried it there. A discharging abscess existing, an exploratory incision was made—and the watch found and extracted. The patient died a short time afterwards.

Health of Baron Liebig.

The *Pharmaceutical Journal* announces, on the authority of a letter just received from Baron Liebig, that the re-establishment of the health of that world-renowned chemist is not yet perfectly complete.

The System of Fagging.

A prize of £50 has been offered by a lady for the best Essay upon the system of fagging, as practised among children at public and other schools. The essays will be abjudicated upon by Dr. Edmunds, of Fitzroy square, London, and must be delivered on or before March 31st.

Statistical Fallacies.

Mr. Matheson, of the Dublin General Register Office has issued a *brochure* on the Irish census, in which he alludes to the fallacious nature of conclusions arrived at from local statistical facts, unless regard be had to the special circumstances which affect each locality. He quotes four notes appended to the English Census Returns, which it appears would not form part of the Irish Returns, but in the absence of which the returns would produce a perfectly erroneous impression. The increase or decrease of population in these four districts were dependent on purely local causes, and not at all on the causes usually assigned for decrease in population.

Mr. Matheson says :—

"A consideration of the two schemes will show that the English classification is far superior to that adopted in

the Irish Returns, which on investigation will be found productive of many anomalies. Thus, under the head 'Ministering to Furniture' are included watch-glass makers, gate-keepers, colliery overseers, and colliery contractors. Land surveyors and sack makers appear as 'Ministering to Food.' Jewellers are returned as 'Ministering to Clothing;' a tar dealer and grease manufacturers as 'Ministering to Conveyance and Travelling;' organ builders, as 'Ministering to Amusement;' Botanists, as 'Ministering to Health; and a Government stationery officer, and sealing wax makers, as 'Ministering to Literature and Education.'"

Faults of the Irish System of Registration.

We have frequently adverted to the ineffectiveness of the system of Registration of Births and Deaths in Ireland as evidenced by the returns of the Registrar-General. The apparently low rate of mortality indicated by these returns as existing in Ireland, has been seized upon by the author of a recent pamphlet on the Irish Dispensary system, and by those who are anixous to assimilate the English system to that in Ireland, and who are, therefore, representing the Irish system as nearly perfect. This party quotes the lower numerical ratio of deaths in Ireland, and suggests that the dispensary system should be credited with saving all the lives represented in the returns. The real fact is that the mortality in Ireland may be as great or greater than in England, for aught we know, but that a third of the deaths are not registered at all. In reference to this matter, Mr. Matheson, of the Dublin Register Office, says:—

"It will be seen from the Quarterly Returns of Births, Deaths, and Marriages, that the registration of deaths is far from being perfect. This is mainly owing to the omission in the Irish Act of a clause corresponding to that in the English statute, which requires a certificate of registration to be obtained before burial, a provision which, in the sister country, has secured a complete record of deaths. The defective registration is not only to be regretted, from its being an indication that the people have not learned the benefits resulting to themselves from compliance with the law, but because it prevents practical use being made of the figures, it not being possible to estimate the deficiency except by comparison with England, the population of which is very differently circumstanced."

Midwifery at Edinburgh.

The recent riots in the University seem to have given rise to various mis-statements. Among these, we may mention the alleged crowded class-rooms of the extra-academical lecturers on midwifery. We are assured by a gentleman who was in Edinburgh all last week, and had opportunities of knowing, that Dr. Duncan had nine pupils, and Dr. Keiller five, while the new University Professor's class was not under seventy. The interest of the public in what has occurred make it worth while perhaps, to confront general statements with facts.

The late Mr. Stilwell.

We have to announce the death of James Stilwell, F.R.C.S.Eng., at the age of seventy-three. He was one of the first gentlemen to take the Fellowship of the English College by examination. He practised for many years at Uxbridge. He had some time retired from professional duty, but gave his son, Dr. H. Stilwell, the benefit of his aid in conducting his private asylum.

The Constitution of the Medical Council.

We have reason to believe that a feeling exists in the Council of the Royal College of Surgeons in England that that important Corporation is inadequately represented, as regards numbers, in the Medical Council. It is felt that the influence of bodies in the Medical Council are by no means proportionate to their rank amongst medico-educational bodies, and it is probable that, in any question of reform of the Medical Council, that question will be vehemently raised.

The Sowing of Scarlatina Seed.

A novel and, from its universality, a very alarming channel for the dissemination of scarlatina has been brought under notice by the medical staff of the Children's Hospital at Birmingham, and the investigations instituted by them bear all the impress of reliability. Experiments have been made which point most conclusively to the fact that scarlet fever is communicated in numberless cases through the medium of the laundry. It has always been a recognised fact with medical men that the clothing of fever patients is a medium of infection, but it is only now the important fact has been elicited that the mixing of such clothes with others in the wash is an active agent in the spread of the disease. The experiments at the Children's Hospital have resulted in the establishment of a very important matter—viz., that when the clothes of the patients in the infectious ward are washed separately from those of the other patients, those other patients do not incur scarlet fever. The observation of the medical staff having been drawn to this fact, they carried out the principle still further, and watched its development with the narrowest care. Among the results it was established that the patients in the ward over the laundry were more frequently attacked than those in distant wards. Now, if—as seems clear from these experiments—the fever germs are not destroyed by water at 212 deg. Fahrenheit, we have the startling fact that every laundry is liable to be turned into a fever manufactory whenever thoughtless or ignorant persons send the clothes of patients to be washed there. The question is one of the utmost gravity, and its importance to labourers in the field of sanitary science cannot be overrated.

Medical Conscience Money.

We notice in the *Indian Medical Gazette* a modest business note to the effect that Dr. G. H. Chesnage had forwarded to the editor a cheque for Rs. 120, being arrears of subscription to the Irish Royal Medical Benevolent Fund Society for twelve years. This is, indeed, a restitution of conscience money, alike honourable to the donor and to the Society whose claims on the charity of the Profession have made themselves heard so many thousand miles from home. The Branch of the Fund, established in Bombay, has deserved the gratitude of the Society, and it is honourable to the Profession that its members, under no personal influence or example, are mindful of their duty to the widow and orphan of their brother.

Staff-Assistant Surgeon Wearne has resigned the Assistant-Professorship of Pathology at Netley, after four years' tenure of that important office.

The Corporations and the Council.

Mr. Gay's resolutions at the Council of the Royal College of Surgeons have been withdrawn, but will probably be again brought forward. We do not think the College has the most distant chance of increasing its number of representatives in the General Medical Council; nor do we desire this. Let Mr. Gay adopt the simple programme of giving the Fellows and Members the right to elect their representative, and he will find all true reformers ready to support him. We may say that Dr. Humphry, who is said to have been against such a move, is the representative of the University of Cambridge in the General Council, and that the election in that University is open, and that, therefore, he represents the University as a whole. Can he not believe that the College should be as liberal?

The late Dr. Anderson.

Dr. Thomas Anderson, who died on the 26th ult., was the Director of the Calcutta Botanic Gardens. Though only thirty-eight years of age, he had made his mark in those branches of science in which he most delighted. He was in India through the mutiny, and present in several encounters. He deserved great credit for the manner in which he pushed the cultivation of cinchona in India, and more recently he strove to do as much for ipecacuanha. He was in Edinburgh at the time of his decease, preparing a collection of ipecacuanha plants at the Botanic Gardens to send out to India. We hope his untimely decease may not hinder the work he had at heart.

Refusing to take Warning.

On two different occasions in these columns, within the last seven weeks, we drew attention to a certain Board of Guardians, who censured a certain medical officer for ordering nourishment for what the intelligent Board called *persons in dying circumstances*. We warned them of what one day would happen, and refusing to take advice, we again find our attention directed to the proceedings of an inquest held upon a man whom the officers of the same Board refused to succour, and who accordingly died whilst suffering from typhoid fever of destitution or starvation. The evidence of the medical attendant is, *He* (the deceased) *would have had a better chance of recovery had he had the nourishment I ordered*. There has been an unfortunate want of efficiency in applying Poor-law relief to the emergencies of the case, the man died through want and there is no mistake about it. The following condensed statement was made by the Coroner :—

1. On the 3rd October the medical officer should have stated in his certificate the extra support required. 2. When the deceased's wife was before the Guardians, and the removal of the deceased was required, some inquiry should have been made as to his fitness for removal, and she should have been informed of the arrangements. 3. The deceased's friends after receiving the certificate of the 5th October, should have applied to the overseers, either before or after having gone to the relieving officer's house to officiate in his absence. 5. The relieving officer having received the certificate of the 5th October on the following (Thursday) morning, should have given an order at once in compliance with the certificate.

And in these remarks the jury concurred. A third time, and we hope it is the last, we bid the Guardians and officers of the Mansfield Union beware, or something worse may result than the occurrence which has just happened at South Normanton. We do not make useless observations in these columns, and if this particular Board has not read what we have already written on the fact, we hope some subscriber in the neighbourhood will direct their attention to them, for a similar occurrence to that taking place at Normanton, and which we foretold would one day happen, will be a most serious affair for the officers of the Mansfield Union.

Our Widows and Orphans.

From the earliest period of creation the relief of the destitute widow or orphan has been considered the most meritorious of service. The Pagans themselves recognised this fact, and were never forgetful of its appliance, but when the needy are of our own kin, whether the relationship be that of country, profession, or creed, it has ever been considered as an additional claim upon the charity of its kinsmen.

In a recent article in one of our medical contemporaries, it is there laid down "broadly, as a general principle," that the widows or orphans of deceased members of the Profession have "no legitimate claim upon the charity of the Profession." The writer in question feels very acutely the appeals made to his charity; no doubt his ears have been dinned by the cry of want, and his eyes scalded at the sight of the orphan's tears, but in spite of all this terrible stimulant to his benevolence, he thinks that because their father has been unsuccessful, and, therefore, according to his code of ethics, improvident, the little one's cry for bread should be referred to the parish official, and they themselves shunted off to the door of the poorhouse. This is a fearful piece of logic, and against its unkind and un-Christian bearing too much cannot be said. We believe that those amongst us will not follow the advice of this writer, that they will not hold out the penny whilst they are enquiring whether the father or husband had been improvident or parsimonious, waiting to return it to their pocket in case the investigation was not satisfactory. No, but let them remember, in the plenitude of their success, that the widow or orphan of their poor brother has but few friends, and that they have a claim of kindred which should never be forgotten.

Prospects of Female Doctors.

The *Pacific Medical and Surgical Journal* says whilst the conservative members of the Profession are insisting that women are physically and mentally unfit for the study and practice of medicine, and must not be tolerated or acknowledged as regular practitioners, the incentives and facilities for the medical education of females are increasing notably in all directions, both in Europe and America. A wealthy citizen of Boston has lately bequeathed nearly a million and a half of dollars for the endowment of an institution for females—medicine being first named in the list of branches to be taught. If our good brothers in Philadelphia, and elsewhere, members of the Pennyslvania State Society, and of the National Association, and other organized bodies, who condemn as heretics all doctors in petticoats and their abettors, do not throw off their stiff stocks and suffer their heads to turn on their axis, they will run the risk of being crowded out of the Profession by the well-trained graduates of crinoline, who are mustering in these latter days like the soldiers of Germany. The opponents of female doctors are really their best friends. They do not

understand the nature of women, or they would not attempt to thwart her aspirings by proscription. "When she will she will, you may depend on't."

Importance of Proper Alimentation.

CRITICISING a paper which says that the subjects of dyspepsia comprise "four-fifths of the entire population," the *Pacific Medical and Surgical Journal* says, we think one-fifth would be nearer the mark, even restricting the range to adults—for children very seldom have dyspepsia. The term does not apply properly to the transient rebellion of the stomach against abuse. A man is not a dyspeptic because he cannot play the glutton with impunity by an hour's industrious stuffing; or because he cannot sit till midnight taking in oysters and lager, and then carry the load home quietly.

Why don't the Doctors use Common Names?

A PHYSICIAN in Texas writes to the *Philadelphia Medical and Surgical Reporter*, extolling the juice of the leaves of "*cockle-burr*" as a hemostatic, and inviting practitioners everywhere to give it a trial. Upon this, one other *Medical Journal* asks what is the "cockle-burr?" and tells us that there are probably half-a-dozen plants of that name in the United States—each section of country having one of its own. So much for the advantage of using common names instead of precise and definite scientific appellations, which cannot lead to error.

Royal College of Surgeons of England.

TWENTY-SIX gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 8th inst. Thirteen other candidates were examined; but failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their anatomical and physiological studies for three months. At this meeting of the Court the recently elected examiners, Messrs. Henry Hancock, Vice-president of the College, surgeon to the Charing-cross Hospital; Frederick Le Gros Clark, surgeon to St. Thomas's Hospital; and William Scovell Savory, F.R.S., surgeon to St. Bartholomew's Hospital, late Professors in the College, took their seats as members of the Court of Examiners. The next pass examination for the diploma of membership of the College will commence on Friday next.

The Yellow Fever in Spain.

THOSE who are fond of coincidences will find a remarkable chain of them in the fact that in 1821, when the yellow fever last attacked Barcelona and its environs, it appeared on the same day as it did this year; it broke out at first in the same street, suddenly increased on the same day, and attained its *maximum* of victims on the same day. In 1821 it ceased on the 11th of November, and should, as is fervently to be hoped, a similar fate befall it when that date arrives this year, the series will be complete. On the 26th, the number of fresh cases amounted to forty-four, and the deaths to twenty-two; in Alicante they were twenty-nine and nineteen respectively; in Valencia one case only. In Palma de Majorca four persons were attacked between noon on the 22nd and the same hour on the 24th, and eight died; on the 25th the totals were ten and six. On the 27th the numbers in Barcelona and Alicante showed neither increase nor decrease; Valencia had not a single case.—*Gibraltar Chronicle*, Oct. 31.

Moonstruck Fish.

THE generation of an irritant poison by a peculiar degree of decomposition in shellfish is a familiar fact, and cases of acute, but transient, poisoning from this cause are frequent in hospital practice. We are not, however, equally familiar with another change to which fish is said to be liable, and which, if it be real, is a very remarkable metamorphosis of animal matter from a very unwonted cause. In the August number of the *Australian Medical Journal*, Dr. Munway notices at length the generation of poison in fish by the action of the moon's rays.

About two years previously he had been engaged as chemist and geologist, to go to the south-west coast of Tasmania. While returning, they caught a number of barracoutta, which were cut open down the back, cleaned, sprinkled with a little salt, spread out on the deck, and covered with a sail during moonlight, and were eaten without any unpleasant effect. On a subsequent occasion he purchased one and sent it to his lodgings. On his return, the landlord informed him that the fish was moonstruck and unwholesome. Being sceptical, he resolved to test the truth of it. The fish, which was fried for breakfast, was found to have the usual taste and flavour; but about half an hour after the meal, his wife complained of headache and nausea, heat in the face and head, and a sensation as of the head and face swelling greatly. Her countenance became suffused of a deep red, and the headache increased. Dr. Munway was also affected with similar symptoms, but had no headache. Brandy was immediately administered to the extent of two or three wine-glassfuls which very soon relieved them. The redness of Dr. Munway's face and head gradually diminished; but not so with his wife, whose symptoms were only partially mitigated. Having occasion to leave home for a couple of hours, and finding, on return, that his wife still complained of severe nausea and headache, he gave her some brandy and water. This almost immediately produced a full emetic discharge, whereby the severe and distressing symptoms were quickly removed. On inquiry of the landlord how he knew the fish was moonstruck and poisoned, he replied that there was a peculiar soft and slimy feel to the finger when rubbed along the lower part of the belly at the junction of the two sides.

Whether the other kinds of fish, such as the trumpeter, butter-fish, &c., are similarly affected, he does not know, as Dr. Munway has never seen them cut up and exposed for sale like the barracoutta; he is disposed to believe that all fish are liable to the same action of the moon's rays.

The symptoms detailed by Dr. Munway are not at all similar to those which arise from the use of decomposed shellfish, so that although we may have a difficulty in assuming that the action of the moon has anything to say to the development of a poison, yet we know, as yet, of no metamorphosis which would give rise to such symptoms as are detailed by Dr. Munway, It is a fact well known to photographers that moonlight has no chemical or actinic power whatever, and it can, therefore, hardly exercise any such effect on animal matter.

Mr. John Clay has been elected Obstetric Surgeon to the Queen's Hospital, Birmingham.

Scarlatina is epidemic at Liverpool, and relapsing fever has not abated there.

Dr. Humphrey Sandwith has published in *Macmillan* an article on "The War and the Ambulance."

Sir Stafford Northcote is to be Chairman of the new Royal Commission on Friendly Societies. Medical men ought to be in the Commission, none are so familiar with the working of these associations.

The Senate of the University of London have re-appointed Dr. Storrar, Member of the General Medical Council. Dr. Storrar's position would be more honourable were he elected by the Graduates of the University.

Dr. Gavin Milroy has been invited to go to Trinidad as the representative of the Royal College of Physicians of London, in an enquiry to be made into the modes of treatment of leprosy.

Small-pox still prevails in London. A friend informs us that he has lately met with it in the most malignant form. There were twenty-three deaths from the disease in the last weekly return, and yet the vaccino-phobiacs have not displayed any signs of returning reason.

We learn that Dr. William MacCormac, of Belfast, Surgeon to the General Hospital in that town, and late *Chef d'Ambulance* at Sedan, is about to take up the practice of his Profession in London. It is understood that he will probably be connected with St. Thomas's Hospital.

A General Meeting of the Royal Irish Academy was held on Monday evening last, when the following papers were set down for reading:—

1. Rev. Maxwell Close, "On M. Delaunay's Views relative to the condition of the interior of the earth."

2. Samuel Ferguson, LL.D., "On the difficulties attendant on the transcription of Ogham Legends, and the means of avoiding them."

3. W. Archer, Esq., "On some new or little-known freshwater Rhizopods."

Horse-flesh eating seems to be quite an acquired taste, like tobacco smoking, and as difficult for some persons to abandon as smoking is. The poor French soldiers who eat so much of it in Metz don't like to go back to mutton and beef. This is a lesson to us all not to think any food common or unclean. Philosophers of the Diogenes school, who desire to rail against the faults and follies of their neighbours, will be starved with more difficulty if they consent to become hippophagists. Cats, too, seem admirable makeshifts for rabbits.

The first meeting of the Royal Medical and Chirurgical Society was an interesting one. Messrs. Fagge and Durham related some cases in which they had successfully treated Hydatid Tumours of the Liver by Dr. Althaus' plan of Electrolysis. Nine cases were given where successful results were obtained; no suppuration followed which is sometimes observed after the ordinary process of tapping. There is some doubt, however, whether this plan may not succeed only in so far as the process of acupuncture by the grooved needle has done, by allowing the escape of the fluid contents of the cysts.

SCOTLAND.

University of Glasgow.—The new University was formally opened on Monday, the 7th, His Grace, the Duke of Montrose, Chancellor, presiding. The proceedings were held in the large hall, which is to be devoted to the Hunterian Museum. His grace was accompanied to the hall by the Members of the Senatus Academicus, the Provost of Glasgow, the Marquis of Bute, the Chancellor, and the Principal of the University of Edinburgh, the Lord Provost of Edinburgh, Mr. Gordon, M.P., and others. The Introductory Address to the students was delivered by Professor Lushington, Senior Professor in the University. In the evening the event was celebrated by a banquet, at which the Members of the Senatus, the Duke of Montrose, the Lord Advocate, the Lord-Justice General, Sir. A. Grant, the Lord Provost of Edinburgh, the Marquis of Bute, and others, were entertained by the Provost, and a number of subscribers to the University buildings. The new University buildings are placed on the summit of Gilmare hill, and occupy a space of four acres. In length the building is 600 ft., and 300 in breadth, and it will be divided into two quadrangles by the common hall, which, however, is not yet constructed. There is a central tower of 150 feet in height, and surmounting the common hall there will be a graceful spire 170 feet high. A sum of £60,000 is still required to complete the building.

In the *Edinburgh Medical Journal* for this month, Professor George Buchanan, of Glasgow, relates three cases of successful excision of the lateral half of the tongue. Dr. Buchanan states that a patient, on whom he operated in 1865, is still well, and free from any return of the disease.

Mr. W. A. Jamieson, Berwick-on-Tweed, recommends injections of carbolic-acid lotion in metritis. Apart from its disinfecting and deodorizing properties, he considers carbolic acid to be "a special sedative to the uterine nerves." In any case, where from the length of the labour, or from the use of instruments there is a risk of metritis following, the attack, he believes, may be warded off by employing the injection early, within a few hours after the completion of labour, when the primary fatigue has been recovered from. The strength of the lotion should be one or too drachms of acid to each pint of warm water.

As compared with last year, the number of medical students at the University of Edinburgh who have already matriculated shows an increase of fifty.

A Rival to the far-famed Mont Cenis tunnel is announced (says *Nature*) from America. The tunnel through the Hoosac Mountain, on the Troy and Greenfield Railway, is steadily progressing, and has now overcome the great difficulties with which it started. It is 4¾ miles in length (more than half that of Mont Cenis), and of this distance above one-third is already penetrated. The work is actively proceeding night and day from both ends, and it is expected it will be finished before the expiration of the contract in 1874.

PHARMACY BILL FOR IRELAND, PROPOSED BY THE GOVERNOR AND COMPANY OF THE APOTHECARIES' HALL, DUBLIN.

DRAFT BILL

To regulate the Practice of Pharmacy in Ireland, to institute a Pharmaceuticai Society, and to alter and amend the Act passed by the Parliament of Ireland, in the Thirty-first year of the Reign of His Majesty George the Third, intituled "An Act for the more Effectually Preserving the Health of His Majesty's Subjects, for Erecting an Apothecaries' Hall in the City ef Dublin, and Regulating the Profession of an Apothecary throughout the Kingdom of Ireland."

WHEREAS it is expedient, to enable the Governor and Company of the Apothecaries' Hall of Dublin to grant Licences to persons (other than duly-qualified Apothecaries) to assume the name of Pharmaceutical Chemists, and to keep open shop for the retailing, dispensing, or compounding of Prescriptions of duly-qualified Medical Practitioners, and also to grant Certificates enabling persons to be engaged or employed as Students, Apprentices, or Assistants, respectively.

And whereas, it is expedient and necessary that such persons should possess a competent practical knowledge of their business, and to that end, that from and after the day herein named, all persons should, before commencing such business, be duly examined as to their qualifications and practical knowledge, and that a Register should be kept, as herein provided, and that there should be instituted a Pharmaceutical Society for Ireland, and also that the Act passed in the Parliament of Ireland, in the Thirty-first year of His Majesty George the Third, intituled "An Act for the more Effectually Preserving the Health of His Majesty's Subjects, for erecting an Apothecaries' Hall in the City of Dublin, and Regulating the Profession of an Apothecary throughout the Kingdom of Ireland," should be amended :—

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same as follows :—

1. From and after One Thousand Eight Hundred and Seventy-one, it shall be unlawful for any person, other than a duly-qualified Apothecary, to sell or to keep open shop for retailing, dispensing, or compounding Medical Prescriptions in Ireland, unless such person shall be a Pharmaceutical Chemist within the meaning of this Act, and be registered under this Act.

2. Pharmaceutical Chemists within the meaning of this Act shall consist of all persons who shall be duly examined and licensed in Pharmacy, and registered as Pharmaceutical Chemists under the provisions of this Act.

3. The Examiners for the purposes of this Act shall consist of the Governor or Deputy-Governor, with six members of the Court of the Apothecaries' Hall, who examine on the subjects specified in Clause 4 of this Act, together with six other Examiners selected by Members of the Pharmaceutical Society of Ireland, provided that until said conjoint Board be formed, the examinations may be carried on for the time being by the aforesaid Members of the Court of the Apothecaries' Hall.

4. All such persons as shall have been so appointed to conduct examinations under this Act shall be, and the same are hereby declared to be, fit and proper persons to conduct all such examinations as are provided for or contemplated by this Act, and shall respectively have full power and authority, and are hereby authorised and required to examine all persons who shall present themselves for examination under the provisions of this Act in their knowledge of the Latin and English Languages, in Arithmetic, in Botany, in Materia Medica, in Pharmaceutical and General Chemistry, in Practical Pharmaco, in the British Pharmacopœia, and such other subjects, as may from time to time be determined, by any by-law of the General Council of the Pharmaceutical Society of Ireland. Provided always, that such examinations shall not include the Theory and Practice of Medicine, Surgery, or Midwifery, or any branch of Medicine or Surgery ; and the said Examiners are hereby empowered to grant or refuse to such persons, as in their discretion may seem fit,—Certificates of competent knowledge and qualification and skill to exercise the business or calling of Pharmaceutical Chemists, or, as the case may require, to be engaged or employed as Students, Apprentices, or Assistants, respectively ; provided, nevertheless, that in case of rejection, a rejected Candidate may present himself for re-examination after six months.

5. The Council of the Pharmaceutical Society of Ireland shall, within three calendar months after its formation, appoint a fit and proper person to act as Registrar under this Act, and said Council shall have power to remove the said Registrar, or any future Registrar to be appointed under this Act, from said office, and from time to time to appoint a new Registrar in the room of any Registrar who may die, or retire, or be removed from office, as aforesaid, and also to appoint and remove from time to time a Treasurer, and such Clerks and other Officers as may be requisite for carrying out the purposes of this Act, and also to pay suitable salaries to the said Registrar, Treasurer, Clerks, and Officers, provided that pending the formation of such Society, the Governor and Council of the Apothecaries' Hall shall appoint fit and proper persons as Registrar, Treasurer, Clerks, and Officers.

6. For every examination and registration, and for every certificate of same such reasonable fees or charges shall be paid as shall from time to time be fixed and determined by any by-law to be made by the General Council of the Apothecaries' Hall of Dublin, or by the Council of the Pharmaceutical Society, as the case may be, provided always, such fees or charges shall at no time exceed the fees laid down respectively in each case in Schedule (A) to this Act annexed, and such fees shall be paid to the Treasurer, and shall by him be applied as the said Council of the Apothecaries' Hall or of the Pharmaceutical Society shall direct in furtherance of the provisions of this Act.

7. The Registrar to be appointed under or by virtue of this Act shall from time to time make out and maintain a complete Register of all persons certified as Pharmaceutical Chemists by the Examiners appointed under this Act, also of all persons certified in like manner as Apprentices, Students, or Assistants, respectively, and shall keep a proper Index of the Register, and all such other Registers and Books as may be necessary for giving effect to the by-laws which shall from time to time be made in conformity with the provisions of this Act.

8. It shall be the duty of the Registrar to make and keep a correct Register, in accordance with the provisions of this Act, of all persons who shall be entitled to be registered under this Act, and to erase the names of all registered persons who shall have died, and from time to time to make the necessary alterations in the addresses of the persons registered under this Act. To enable the Registrar duly to fulfil the duties imposed upon him, it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to carry on business, or has changed his residence, such letter to be forwarded by post as a registered letter, according to the Post Office regulations for the time being, and if no answer shall be returned to such letter within six months from the sending of the letter, a second of similar purport shall be sent in like manner, and if no answer be given thereto within three months from date thereof, it shall be lawful to erase the name of such person from the Register, provided always, that the same may be restored by direction of the Council of the Apothecaries' Hall of Dublin, or of the Council of the Pharmaceutical Society, as the case may happen to be, should they think fit to make an order to that effect.

9. No name shall be entered in the Register, except of persons authorised by this Act to be registered, nor unless the Registrar be satisfied by the proper evidence that the person claiming is entitled to be registered ; and any appeal from the decision of the Registrar may be decided by the Council of the Apothecaries' Hall of Dublin, or of the Pharmaceutical Society, as the case may be ; and any entry which shall be proved to the satisfaction of such Council to have been fraudulently or incorrectly made, may be erased from, or amended in, the Register, by order in writing of such Council.

10. The Registrar shall, in the month of January, in every year, cause to be printed, published, and sold a correct Register of the names of all Pharmaceutical Chemists, and a correct Register of all persons registered as Students, Apprentices, and Assistants, and in such Registers, respectively, the names shall be in alphabetical order, according to the surnames, with the respective residences, in the form set forth in Schedule (B)

to this Act, and such printed Registers shall be called "The Registers of Pharmaceutical Chemists, and of Pharmaceutical Students, Apprentices, and Assistants for Ireland," and a printed copy of such Registers for the time being, purporting to be so printed and published, as aforesaid, or any certificate under the hand of the said Registrar, and countersigned by the Governor or two Members of the Council of the Apothecaries' Hall of Dublin, or by the President or two Members of the Pharmaceutical Society, shall be evidence in all Courts, and before all Justices of the Peace, and others, that the persons therein specified are registered according to the provisions of this Act, and the absence of the name of any person from such printed Register shall be evidence, until the contrary shall be made to appear, that such person is not registered according to the provisions of this Act.

11. Any Registrar who shall wilfully make, or cause to be made, any falsification in any matter relating to the said Registers, and any person who shall wilfully procure, or attempt to procure, himself to be registered under this Act, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding or assisting him therein, shall be deemed guilty of a misdemeanor, punishable by fine or imprisonment, and shall, on conviction thereof, be sentenced to be imprisoned for any term not exceeding twelve months.

12. Every Registrar of Deaths in Ireland, on receiving notice of the death of any Pharmaceutical Chemist, or Pharmaceutical Student, Apprentice, or Assistant, shall forthwith transmit by post to the Registrar under this Act a certificate, under his own hand, of such death, with the particulars of the time and place of death; and on receipt of such certificate, the said Registrar under this Act shall erase the name of such deceased Pharmaceutical Chemist, or Student, Apprentice, or Assistant, as the case may be, from the Register, and shall transmit to the said Registrar of Deaths the cost of such certificate and transmission, and may charge the cost thereof as an expense of his office.

13. From and after the One Thousand Eight Hundred and Seventy-one, any person who, not being a duly-registered Pharmaceutical Chemist, or duly-qualified Apothecary, shall keep an open shop or wareroom for the retailing, dispensing, or compounding medical prescriptions, or who shall take, use, or exhibit the name or title of Apothecary, Pharmaceutical Chemist, or Pharmaceutist, or Pharmacist, or Dispensing Chemist, in Ireland, or make use of any sign or title, implying that he is a qualified Apothecary, or that he is registered as a Pharmaceutical Chemist under this Act, or any Pharmaceutical Chemist or Apothecary who shall take or employ any person as Student, Apprentice, or Assistant, without such person having obtained the proper certificates hereinbefore directed, or who shall compound any medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia, each and every person so offending shall for every such offence be liable, on summary conviction before one or more Justices of the Peace, to pay a penalty of five pounds, and when recovered, such penalties shall be applied to the purposes of this Act; but nothing in this Act contained shall prevent any person from being liable to any other penalty, damage, or punishment, to which he would have been subject if this Act had not passed.

14. Upon the decease of any Pharmaceutical Chemist or Apothecary actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such Pharmaceutical Chemist or Apothecary, to continue such business for a period not exceeding six months, and provided such business shall be *bona-fide* conducted by a duly-qualified Apothecary, or by a Pharmaceutical Chemist registered under this Act, provided always, that registration under this Act shall not entitle any person so registered to practise Medicine or Surgery, or any branch of Medicine or Surgery.

15. It shall, nevertheless, be lawful, anything to the contrary notwithstanding, for the Examiners appointed under this Act to admit to examination any Chemist and Druggist who shall have been in business, as such, on his own account for a period of not less than five years before the passing of this Act, and who shall, within six months after it has passed into law, make application in writing for examination to the Registrar under this Act, accompanied with a Certificate according to Schedule (C) to this Act; and every such Chemist and Druggist who shall have satisfied the Examiners as to his knowledge, skill, and competency to carry on and conduct the business of a Pharmaceutical Chemist, shall receive the Certificate of Pharmacy from the said Exnminers, and shall be entitled to be placed on the Register of Pharmaceutical Chemists of Ireland; and the person so certified shall pay the same fees as other Pharmaceutical Chemists under this Act; provided always, that in case of rejection, the rejected candidate may be re-examined after six months.

16. It is hereby further enacted, that a Pharmaceutical Society shall be instituted, to be named, "The Pharmaceutical Society of Ireland;" and authority is hereby given for the formation of such Society; and in order to the formation of same it shall be lawful for every person who has been duly licensed and registered as a Pharmaceutical Chemist by this Act, and also for every duly-qualified Apothecary, upon payment of an annual subscription of One Guinea each to the Treasurer appointed under this Act, to become a member of said Society, and to have a voice and vote in all general meetings of the Society; and the Governor and Council of the Apothecaries' Hall of Dublin are hereby authorised and required, within one year after the passing of this Act, to convene a meeting of all members of the Society, to be held at their Hall in Dublin, by written or printed summonses, to be issued ten days previous to the day agreed upon for holding such meeting; and it shall be lawful for the members in assembly at such meetings to appoint a President, Vice-President, Council, and Secretary, for conducting the business of the Society; and like meetings of the Society shall be holden annually.

17. At all general meetings of the Society, it shall be lawful for the Society to make all such By-laws and Rules for the advancement of Pharmacy and for the good government of the Society as the members present shall in their wisdom, and by a majority of votes determine, provided always, that said By-laws and Rules shall be consonant with, and not contrary to, any of the provisions of this Act; and it shall also be lawful for the Society at every such annual meeting, for the members present to elect from among themselves, by a majority of votes, six persons to be conjoint Examiners with the Examiners on the Pharmacy Court of the Apothecaries' Hall, to record their votes as to the merits of the several candidates who have undergone examination.

18. The parts hereinafter mentioned of the aforesaid Act of the "Thirty-first of George the Third, chapter thirty-four," shall be, and the same are hereby repealed; that is to say, so much of the tenth clause as relates to seven years' apprenticeship, the whole of the twenty-third clause, so much of the twenty-forth clause as relates to fees for Certificates, and the whole of the twenty-fifth and twenty-sixth clauses.

19. This Act may be cited as the Pharmacy Act, Ireland, 1870.

20. This Act shall apply to Ireland only.

SCHEDULE A.

Scale of Fees for Certificates.

Apprentices and Students	... ...	2 Guineas.
Assistants	... ...	3 Guineas.
Pharmaceutical Chemists	... ...	5 Guineas.
The Fee for Registration	... ...	5 Shillings.

SCHEDULE B.

Name.	Residence.	Date of Registration.
A. B.	Grafton street, Dublin.	Jan. 10th, 1871.
C. D.	Patrick street, Cork.	March 4th, 1871.
E. F.	Corn market, Belfast.	June 15th, 1871.

SCHEDULE C.

Certificate to be signed by a *duly qualified Medical Practitioner* or *Magistrate* respecting a person who was in business as a Chemist and Druggist in Ireland for five years on his own account.

To the Registrar appointed under the Pharmacy Act, Ireland, 1871.

I, residing at in the County of hereby certify that I am a duly qualified Medical Practitioner, (or Magistrate,) and that to my knowledge residing at in the County of has been in business as a Chemist and Druggist on his own account for a period of not less than five years.

(Signed)

This day of 1871.

Literature.

TWELFTH REPORT OF THE MEDICAL OFFICERS OF THE PRIVY COUNCIL BLUE-BOOK.

This Blue-book contains some very interesting matter among a good deal that is unreadable. Among the most important of all the reports, is one by the deep-thinking Dr. Burdon Sanderson, entitled, "Introductory Report on the Intimate Pathology of Contagion." The author first refers to the "Physical Properties of Contagion," and next, to the "Organic Forms which occur in Infecting Liquids." With regard to the former of these points, Dr. Sanderson thinks it proved by Dr. Chauveau and himself, that the contagious principle is neither soluble in water, nor capable of assuming the form of vapour, but that every kind of contagion consists of particles of a very minute character, rarely more than 1-20th thousand in diameter, similar to those described in 1864 by Dr. Lionel Beale as existing in vaccine matter. Dr. Sanderson thinks it probable that the contagium particles "are spheroidal transparent, of gelatinous consistence, of density nearly equal to that of the fluids in which they float, and that they are nearly, although perhaps not exclusively, composed of albuminous matter. With reference to their mode of action, we have examined into these considerations which seem to render it probable that they are organised beings, and that their powers of producing disease are due to their organic development, and we have accepted this doctrine as the only one which affords a satisfactory explanation of the facts of infection." Dr. Sanderson proposes to call the microscopic forms alluded to, *mycrozymes*. With regard to the way in which these organisms work, Dr. Sanderson thinks that "Pepsine is but one of a group of substances which perform, what in a general sense may be called zymotic functions in the animal economy, all of which have this peculiarity in common, that they induce important chemical changes in other kinds of substances, without themselves participating in the transformations they effect. This faculty of causing chemical changes in other contiguous matter is all that is implied when the process of infection is compared to a ferment." We recommend all interested in the progress of positive medical theories to read carefully the admirable report by Dr. B. Sanderson.

Assistant-Surgeon Myers, has published his prize essay * on Heart Diseases among Soldiers, and his work deserves general attention. He commences with a comparison of civil and military statistics, and goes fully into the many causes that have been alleged to give rise to the prevalence of heart disease among troops. The prejudicial construction of the uniform and accoutrements come in for severe blame, and are, in the author's opinion, the special causes which develop cardiac disease. Whatever doubts may still remain in the minds of some, we presume no one will now deny that, the existing mode of clothing our soldiers is highly prejudicial, and if not, the only cause is one of the most potent causes of such interference, with the circulation as would be likely to distress the heart, and after a time even set up organic disease. We are glad this Essay has been published. It is a most useful contribution to the question, and one which ought to be digested by those who are responsible for the existing evils of army tailoring.

Hospitalism.—*Nature* announces that the unpublished manuscripts left by the late Sir James Simpson on the important subject of Hospitalism have been confided to the care of Mr. Lawson Tait, of Birmingham, for completion and editing.

Correspondence.

SUDDEN LOSS OF VOICE OF SINGERS—ITS CURE BY ACONITE—USE OF ACONITE IN VETERINARY MEDICINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Cabarus, a famous homœopathist, who died some months since at Paris, enjoyed a great reputation for curing, with rapidity, the sudden loss of voice, to which singers are subject. This he used to accomplish in a few hours. A person having once sought to learn his secret, "My friend," replied he, "when I die my tomb shall be wreathed with aconite; the allopaths give aconite in doses of a few drops, I, a homœopathist give it by the spoonful, and I enable my patients to sing; that was all I did to Madam Borghi," alluding to some celebrated cantatrice, whose sudden extinction of voice, on the afternoon of a night when she had to sing before a brilliant audience, and perfect cure by Cabarus within a few hours, created a sensation among operatic folk.

Now, a teaspoonful of the stronger tincture of aconite (Fleming's), would in all likelihood be a poisonous dose, but, might our ordinary tincture be given in drachm doses, or is that of the Paris Codex so much weaker? And, setting aside this statement of Cabarus, is there any other evidence that aconite in heroic doses has so remarkable a therapeutic action upon the larynx or bronchi? I saw it recently advertised as an infallible cure for a roarer or broken-winded horse. I fancy that we might often take hints from veterinary practitioners, who generally use telling remedies, and have the corpus vilum to experiment on.

F. M. Luther, M.D.

VIVE MEMOR LETHI.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I think the above advice may be truly given to all the persons employed in very many of the various work-rooms in this Metropolis. Here is a specimen. I was called to visit a young married woman whom I found suffering with rheumatic fever and constipation, the bowels not having been relieved for ten days. Upon expressing surprise at this, she told me she sometimes went *three weeks* without alvine dejection. She is one of eighteen or twenty hands employed at a work-shop, at the machine boot making. The said shop is a very low room at the top of the house. When the gas is lighted, they are all nearly smothered, there are eight gas burners in this room, which is about thirty feet long by ten feet wide. There is a coke stove in the centre of the room, which causes incessant headache to those working near, whilst their feet and legs become stone-cold and ache very much, from the cold air rushing through the crevices in the floor and sides of the room. Hardly a person quite well in the shop. As regards the chinks and crevices, upon making complaints to the proprietor, he told them they must paste them over with brown paper. There is but one water-closet, which is situated just within the gateway in the yard, and which sometimes is quite unfit for any human being to go into. Thus far, my patient's oral deposition. I wonder what *Dr. Cyclops* would say to conservation of the bowels under these circumstances? The young women are at least, I think, very awkwardly fixed in respect of obeying the calls of nature. Only think too this "establishment" being only one of *hundreds* in no better condition. A short time since, I was called to attend a young woman labouring under an attack of *coup de soleil*, occasioned by the sun's rays streaming down through the glazed roof of a low work-room, and much indignation was expressed against me, for freely giving my opinion. What made the case worse, was the fact of the employer's medical adviser, concurring with himself that there was no fault to be found with the room. Sometime since, I was called to a workman in the cabinet-making line, who died from cholera. In this case, although there were several workmen, there was but one convenience, which I found in a disgusting and dilapidated condition, and very badly drained. Some people call out "Where are the Police?" I say "Where are the Sanitary Inspectors"?!

Yours, &c.

Live and Let Live.

THE WAR AND WOUNDED.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I send you further extracts from my war letters.

Oct. 29th.—I have been several times round the wards in Dusseldorf with a Dutch surgeon named Wartmann, and seen many interesting cases. One was a man wounded by a shell in the foot; a large portion of integument was removed, and when he was admitted the wound was sloughy and gangrenous. After being in hospital for two days, profuse hæmorrhage set in, to check which Wartmann tied the posterior tibial at the ankle. This did not control the bleeding, and he tied the femoral in Scarpa's angle, a course which proved successful, and still more, from the moment the femoral was tied the wound began to improve, lose its gangrenous appearance, and healed rapidly. From this and a few other analogous cases, he draws the conclusion that in cases of impending gangrene ligature of the main artery would probably avert the danger.

There were several cases of wounds of the knee-joint, and he holds the same opinion that has forced itself on me, that all cases of knee-joints laid open by gun-shot wounds demand primary amputation to save the patient's life. Three cases we had at Gelsenkenhm died of "irritative hectic," if I may so call it, and when this once sets in, operative interference is found to hasten the fatal result. Wartmann says that resections have turned out very badly; but I saw a large number of amputations of leg, arm, thigh, and shoulder joints, all doing well. I have no statistics, but from what I saw I infer that he has had more than average success. I have been to Strasburg, which has been badly knocked about. The Prussian trenches seem to have been very carefully constructed, as there were seats for the men, and regular fire-places.

I applied for an appointment at Metz, but was told that I would not be sent there officially, but that if I went I would get plenty to do, so I start to-morrow.

I am, &c.,

A. H. MARTIN.

WINTER CLIMATES—BRITISH v., FOREIGN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Once or twice you have allowed me to protest in your columns, against the ridiculous fashion of "going abroad" in search of climatic influences that may be found in nearly equal and in many cases superior suitability in our own island home. The subject is this winter of so much greater importance, in consequence of the dangerous state of the continent, that I hope you will find room for the enclosed extract from your spirited little contemporary the *Echo*. It is a most appropriate article.

I am, &c.

ONE WHO HAS CEASED TO WANDER.

"Of course South Cornwall is not quite the same thing; you can't have oranges on the trees and fields of blue and red anemones, as well as of all the scented blooms which have made Grasse so famous. You can't get ortolans, or sea-urchins—which, ten to one, you wouldn't like if you could. But then to compensate for a sober spring, grey, though not grey after the usual English style of greyness, you have in Cornwall no *mistral*, no wind that cuts you to the bone on the shady side of the street, while in the sun you are baked with heat. You have, what for some invalids is better than any amount of natural beauty, one of the most equable climates in the world; and you may reckon, too, on securing house accommodation far fitter for delicate people than the fine-weather homes of the Provencals.

"Michelet,—shrewd enough on medical matters, though he out-Carlyles Carlyle in historical vagaries long ago warned us, in *La Mer*, that the Mediterranean coast has *un climat apre*, a harsh climate. He prefers the Bay of Biscay, or even the grey rocks of Lower Brittany as a 'change of air' for delicate Parisian mammas and their children. Falmouth or Penzance is just the place he would recommend; you are sure, all along that coast, of being never to hot or too cold—of never meeting those extremes which in Nice, nay even in San Rémo or Mentone, too often put a sadly summary end to the journey in search of health. Both places, too, are really beautiful country. At Falmouth you have a noble 'lough,' sheltered from every wind; while within easy reach for the convalescent is the Lizard country, with its own flora, its fairy rock-work, and its water with the true southern tinge—a bit of Plato's Atlantis still preserved for the confusion of sceptics. At Penzance is a bay which others besides the natives compare with the Bay of Naples. Shelter there is, too, though the east wind, which is so hard upon Torquay, does find out weak points in Penzance, as it does in nearly all our sea-side places. The fact is, 'going abroad' is such an institution that, except Bournemouth, we have no place which has been 'made' simply by its reputation for climate. Anywhere but in England three or four 'nooks' such as abound in the Lizard country—St. Ruan; for instance, or Mullion, would have been seized on by doctor and hotel-keeper. As it is, our people prefer working on established bases, and playing into the hands of the owners of 'building sites.' Thus Torquay existed before it somehow—and not altogether deservedly—become famous; and at Penzance there is a thriving town, which tries by exceptional liveliness to atone for its remote position. There, too, is the best public library west of Bath, and a parade, and a hotel which can hold its own with any in the kingdom. At Falmouth, again, there is a town, a quaint, half Dutch place; and along the hills rise terraces and villas for those who are strong enough to do a little climbing. Either place is attractive enough, and both are very accessible; and though a 'nook' by the Lizard might afford completer shelter, we must become much more Americanised and Germanised before we can hope for our 'nooks' to produce the perfectly-appointed hotel which, wholly self-contained, does away with the need of a town and what a town supplies. Surely, on this showing, a Penzance or Falmouth hotel-keeper is justified in asking, 'Why go further?' Here are the places: and those whose Mediterranean refuge is cut off may very probably find that in South Cornwall they can do better, and at a far less sacrifice."

Medical News.

Royal College of Surgeons of England.—The council of this institution have elected Fellows of the College, Messrs. Peter Marshall, L.S.A., Bedford square, diploma of membership dated March 28, 1828; John Emilius Mayer, of her Majesty's Indian Army, January 18, 1833; and Murdoch Kelburne King, M.D. and F.R.C.S. Edinb., Hull. The last-named gentleman was elected an *ad eundem* Fellow, which, it is stated, is the first occasion in which this honour has been so bestowed since the charter for conferring the Fellowship was granted to the College of Surgeons. The following gentlemen have passed their primary examinations in anatomy and physiology, and, when eligible, will be admitted to the pass examination: Messrs. William Rendall, William Williams, William Dryland, and T. D. Ransford, students of Guy's Hospital; E. L. Archer, A. T. Corrie, and R. W. Stewart, of St. Bartholomew's Hospital; A. J. M. Bentley, J. H. Webster, and Robert Jolly, of Edinburgh; R. J. Carey, and F. G. R. Tooze, of University College; W. J. Foster, and J. J. Hues, of Birmingham; C. De M. Palmer, of Dublin; James Perrigo, of M'Gill, Montreal; J. A. Hendry, of Liverpool; A. J. Johnson, of Toronto and St. Thomas's Hospital; W. McN. Whistler, of Pennsylvania; Donald Murdoch, of Cork and Guy's Hospital; G. H. Heald, of Leeds; Charles Oldman, B. A. Cantab., of Cambridge and Guy's Hospital; Charles Raines, of Hull; W. T. Hawthorn, of the London Hospital; Edward Fretwell, of Sheffield; and E. K. Corbin, of Paris and St. Thomas's Hospital. Thirteen other candidates were examined, but failed to acquit themselves to the satisfaction of the Court, and were consequently referred to the anatomical and physiological studies for three months. The recently-elected examiners, viz., Messrs. Henry Hancock, Vice-President of the College; and Messrs. F. Le Gros Clark, and W. S. Savory, former professors of the College, took their seats on this occasion.

Modern Quackery.—The fable of the Spider and the Fly has a much more universal application than many of us are disposed to admit. Even at the present day, there are more spiders about our path than people imagine; and it is little flattering to our vanity to know that they find a goodly harvest of flies. Some forms of commercial imposture, for instance, ease men of their money; but however loud and violent the denunciations of the sufferers against swindles of this kind, the ruin and desolation they occasion are too insignificant to admit

of a moment's comparison between them and the forms of imposture that lead men and women to imagine themselves victims of the untold miseries born of a diseased imagination. All classes of society, of both sexes, are exposed to the latter kind of imposture, while the greater their wealth and means of happiness and enjoyment, the greater the harvest they afford the quacks. The dupes of the commercial swindles are often men over greedy of gain, for whose protection it is not necessary to take much trouble. What they lose in money they sometimes gain in common sense and prudence; the investment bringing them in a rich return in a way they never expected. There are many people who in early life have lost their fortune and suffered ruin by some commercial swindle, and who have so far profited by their first experience, as ultimately to become wiser and better men. No such compensating process, however, can be alleged for the man or woman who has suffered loss of health, and whose mind and body have been ruined by the withering touch of quackery.—*Dr. Lory Marsh's "Book about Shams."*

The Hospital Accommodation at the Belper Workhouse.—It will be seen from a report of the last meeting of the Belper Guardians, that the Poor-law Board have intimated to the Guardians at Belper, that unless they take some steps to remedy the defects in the Hospital accommodation, which their own special committee unanimously recommended them to do, the Board in London will issue an order to have what is necessary done. The Guardians on Saturday decided to have the letter printed, and a copy sent to each member of the Board, with a summons, to discuss the question next Saturday week. The Poor-law Board intimate that the provision required might be made at a less cost than that which the architect employed estimated would be required for carrying out his plans. At the same meeting Mr. Huish, and Mr. W. Waite, of Duffield, waited on the Board to repeat a request for the appointment of an Inspector of Nuisances at Duffield, where fever prevails, and where sanitary restrictions seem to be greatly needed. The appointment is to be made next Saturday. We hope that next Session the Government will secure the passing of a measure which will provide for every village and rural district a simple and effective means of local Government.—*Derby and Chesterfield Reporter.*

The Burton Sewage.—A weekly paper says:—The Improvement Commissioners at Burton are experiencing the difficulty which has arisen in almost every place where sewerage has been carried out without adequate means being provided for its disposal and disinfection at the outlets. The people who live near the place of exit of the sewage have for some time been threatening an application for an injunction. A large sum has been expended on tanks at Stretton, but the complaints have not ceased, and at the last meeting it was reported that Mr. Leech, of Derby, who acts for the complainants, had renewed the threat of an injunction unless the nuisance were abated, which the Board contend has already been done. As yet the mode of dealing with offensive matter generally adopted in towns only resembles the children's play —"Pass it on."

Naval Medical Service Competitive Examination.—Names of the successful candidates who passed the recent competitive examination for admission into the medical service of the Royal navy, held at the London University between the 7th and 10th November, in the order of merit in which they passed, and the number of marks obtained:—Richard William Coppinger, M.D., Queen's College, Cork, 2,060 marks; William Edward Robson, Royal College of Surgeons, Ireland, 1,700; Robert Waller Biddulph, M.B., Trinity College, Dublin, 1,340; John Jennings, Queen's College, Cork, 1,290; Marcus Allen, Dublin University, 1,205; Henry Beaumont, Royal College of Surgeons, Ireland, 1,130.

British Association.—Dr. Hirst resigns the General Secretaryship of British Association, an honorary post which he has long filled with the greatest advantage to Science.

Royal Society.—*Nature* believes that Mr. W. Spottiswoode will succeed the late Dr. W. A. Miller as Treasurer of the Royal Society.

Apothecaries Society of England.—At a court of examiners held on the 10th inst., the following gentlemen were admitted licentiates of the Society of Apothecaries, viz.:—Messrs. John Heyes Anderton, of Leigh, Manchester; William Cotterill, of Westport, New Zealand; Augustus Edgar Burch Love, of London; and Frederic William Skrimshire, of Hotl, Norfolk. And at the same court Mr. Russell Watson, of University College Hospital, passed the primary professional education.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

*** We must also request our Correspondents to write only on one side of the paper and in *legible* characters. We are often compelled to consign MSS. to the waste-paper-basket merely because it is illegible.

Correspondents not answered in the current Number are requested to look to the Notices the following week.

Dr. Davis, Newry, Dr. Phelan, Mitchelstown, Dr. Nixon, Shinrone, Dr. Deverill, Ardglass.—The *Irish Medical Association Journal* was unavoidably omitted last week.

Dr. Greene, Kilmacthomas.—Letter to hand shall be inserted at earliest possible date.

Pressure on our space obliges us to hold over several abstracts of Introductory Lectures and other communications.

B. A.—You will have no preliminary examination to pass for the fellowship as the degree will be accepted. By all means arrange for that diploma if you intend to practise surgery. The M.B. of your own university would be an excellent medical qualification.

The Editor of the *Medical Mirror* writes to express his regret at some articles quoted from the Medical Press and Circular having appeared without acknowledgement of their source, the printer having forgotten to place, as directed, the name of the Medical Press at foot.

Chirurgus.—Common courtesy would have prevented the misunderstanding. You ought not to have visited the patient. Call on your neighbour, offer an apology, and we hope your former pleasant intercourse will be resumed.

Alpha, Beta, Gamma.—Your *nom de plume* is probably distinct enough. That is better than the confusion we sometimes have. Your qualifications are quite sufficient for the appointment. Send a few select testimonials. Canvassing should be avoided when possible.

Looking out.—We would advise you to apply to Dr. Baxter Langley.

Bachelier-en-Sciences.—You can obtain all the foreign books you want of Messrs. Baillière and Co., King William street, Charing cross.

Puzzled.—It was probably a case of Atalectasis. There ought to have been a P.M.

L. M.—The fee of £2 2s. is very moderate.

P. L.—A division of the fees would be quite right in the case.

L.C.R.—1. You should certainly expect no remuneration for professional attendance on your late partner's widow. 2. We should advise you to make a proposal based on the value of the practice during the past seven years.

F.R.S.—Furnish us with proof of the facts you allege and we promise not to spare the lash, but the position of those involved is so high that, until proved by undeniable evidence, we shall remain incredulous.

Dr. J. H., Horncastle.—Were you to remonstrate with the authorities at your end, you would probably find the annoyance cease. The addresses of our subscribers are printed and checked regularly every week, and the fact of six successive numbers having miscarried, is, in the opinion of our publishers, conclusive proof that some individual has abstracted the copies in transit through the post.

"M. A. B."—The correspondence and advertisements, appearing from time to time, in some of the daily and other papers, and having a signature attached similar to your own, are not likely to be attributed to you; it would be well, however, to adopt some distinctive mark or sign.

Dr. Rooke, the newly-elected Mayor of Scarborough, took his M.D., Edin., 1856; M.R.C.S., Eng., 1858; L.R.C.S., Edin., and L.M., 1855; L.S.A., 1863 (Univ. Edin); he is J.P. for Scarborough, and author of "Debility, the Cause and Consequence of Pulmonary Consumption." "Chapters from the Life of a Young Physician; or, Glimpses of Turkey and the Crimea in 1855-6." "Cod Liver Oil, its Nature and Medical Properties," and other papers.

"THE SEWAGE REPORTS."

To the Editor of "The Medical Press and Circular."

Sir,—Permit me to point out a slight inaccuracy into which has fallen your able writer on the Sewage Question in his contribution of last week. It is an error to class me among the authors of "unprofitable patent inventions" for the treatment of sewage by disinfectants. Condy's Fluid was not introduced by me for that purpose. What I did in connection with this matter was, to demonstrate that in the event of it being determined completely to disinfect sewage, that object could be accomplished by means of my preparation. That the results obtained therefrom were not "futile," may be seen by reference to the table quoted in your last week's paper from Dr. Letheby's report where they are set down as *complete*.

Yours obediently,

Battersea, Nov. 14, 1870. A. B. Condy.

MEDICAL FEES.

To the Editor of "The Medical Press and Circular."

Sir,—May I ask your opinion on a right to fees. Case, a gentleman not twenty-one years old, therefore, not of age in law, applies to me with the sanction of his military tutor, with whom he resides, for professional advice. He is duly informed that my fees are one guinea each consultation, either at my residence or on my visits within reasonable distance, say two miles in town. Over a period of time I was consulted either at my residence or his tutor's twenty-six times, for which I sent in a memo for twenty-six guineas. His father, a wealthy country gentleman, declines to pay the amount as exorbitant, on the ground that his son derived little benefit from my treatment for the skin eruption on his neck, and that his son told him I treated him *for nothing else*, which was a falsehood, as the young man was treated principally by me for another disease, which he greatly neglected, so much so, that I told his tutor of it, and reproved the patient himself, in so much I would not be troubled with him if he did not follow my wishes. Delay in cure decidedly followed his own neglect, and now

Introductory Lecture.

ROYAL COLLEGE OF SURGEONS, IRELAND.

SESSION, 1870-71.

INTRODUCTORY LECTURE DELIVERED BY MR. MORGAN, F.R.C.S.I.,

Professor of Surgical and Descriptive Anatomy, &c.

THE PRESIDENT OF THE COLLEGE IN THE CHAIR.

(*Continued from page* 369).

WHILE I have thus sketched out the general tenor of your studies, and the system in which this College has thought best to exercise your minds, I will now endeavour to illustrate one of the most important features of our art; that by reasoning, based on facts, of apparently trivial import, we may ever, as even now, obtain fresh additions to our store in explaining the apparently inscrutable progress of epidemics, the subtle extension of infectious diseases, or the more apparent, yet equally unopened mystery of contagion. For this purpose, I cannot pass by the opportunity afforded by a consideration of the address of Professor Huxley, President of the British Association for the Advancement of Science, last month, whereby a vista is opened of hitherto unseen dangers and unconsidered causes of disease. It is but a few months since Professor Tyndall drew attention to the composition of the floating particles in the sunbeam of our rooms, and of what materials they may consist. The consideration of these constituents may well excite our curiosity when we find that they may contain living organisms, capable of indefinite propagation, and that, undoubtedly, they can be found to affect living bodies, and be carried in their very circulating fluid.

The theory of Biogenesis started by Redi, has been the subject of much discussion and interest; and the simplicity of his experiment can on this subject be likened to Newton's apple, as the cause of a train of thought being directed to a subject of much import. The progresssive development of this theory, and the series of experiments by Needham, Spallazani, Helmholtz, Schroeder, and Pasteur, gradually carry with them increasing conviction in the existence of atmospheric germs of disease, capable of rapid and copious development as living organisms.

The immense improvements in optical instruments have opened up vast sources of wonder—living specs can now be detected one-forty-thousandth of an inch in diameter. Organisms can be seen in the blood to which the discs themselves are as Brobdinags and Lilliputians. Could Galileo have gazed through the telescope of Lord Ross, what would have been his ideas? Mere spots of milkiness in the heavens, appearing as worlds and systems. What would have been his sensations as he would gaze in wrapt attention while they careered through space? The same applies to the microscope and other instruments of modern make. It is no wonder, now, that extraordinary progress has been made in accuracy and in definition of objects under examination, that we should hope for increased knowledge as to the secrets of contagion and the extension of epidemic diseases.

The remarkable explanation of the Pébrine, or silkworm disease—the existence of microscopic organisms in the shape of the Panhistophyton, and the permeation of these throughout every part of the caterpillar, in the circulatory fluid, and even in the undeveloped eggs of the moth, is extremely interesting; and, as the existence of these organisms, in the shape of cylindrical corpuscles of 1-6th thousandth inch in diameter, or, in fact, one-half that of our own blood discs, can be demonstrated beyond doubt, there is no difficulty in conceiving the importance and bearing of such observations. Indeed, in this very Panhistophyton, we may have, in so insignificant a creature, a practical illustration of contagion, infection, and hereditary taint.

May not these facts which have been proved by earnest and careful study and patience throw some light on the destructive influence of the pyæmic poison, which has so plagued the camps and the hospitals on the Continent, which has carried off so many victims, and has vitiated the greatest care and anxious efforts of the surgeon. May not

the germ of pyæmia be wafted unseen, or carried by friendly hands, may have been unconsciously disseminated on the suitable ground of open wounds, or suppurating surfaces. May we not hope that by directing our attention more closely to this startling subject of the existence of contagious and infectious floating organisms, that we may remove or alleviate this plague. How far the advance in our estimate of floating dangers is of importance, may be gathered from some remarkable facts known to the physician. Thus, in hay asthma, where the most intense distress and *malaise* is caused in some individuals only, by the floating particles of certain herbs. There seems no doubt but that there is a direct irritation by the particles carried through the air, for if you remove the person from the district, or let him wear a cotton respirator the attack ceases directly. May we not in this phenomena, coupled with a more close investigation of the floating germ process, *at least hope* to obtain some clue as to the prevalence of that terrible scourge of our island—consumption ; attacking, as it does so often, the fairest and most promising, when just bursting into manhood or womanhood, too often suggesting the touchingly poetic sentiment, that—

"Heaven gives its favourites easy death."

May we not venture to see in the evidence of contagion, which is not unfrequently forced on some, proof of a process analogous to the Panhistophyton, I have alluded to. If herbaceous particles can be wafted along of such extreme minuteness, as to be capable of filtration by a cotton respirator, and yet when admitted cause the most intense irritation of the pulmonary membrane, in certain temperaments, may not the victim of phthisis breathe forth germs, as in the instances quoted, which will sooner or later, when deposited on a suitable soil, fructify to the destruction of the recipient. The idea may seem startling, but with the present direction given to our knowledge, and the incontrovertible evidences that such things do exist, we should studiously and anxiously enquire into these occult mysteries.

During the past year, we have witnessed the most acutely debated arguments as to the cause and propagation of metria—a disease peculiar to the puerperal condition. An institutions of municipal importance, as a lying-in hospital, and affording vast relief to the city, has been called in question as to its suitability for its purpose, owing to the occasional and fitful eruption of this dangerous and insidious disease. The most keen discussions have taken place as to the cause and origin of this inscrutable affection. Yet, may we not learn a lesson from the microscopical morbific germs of the fly or the silkworm, or the floating particles of the sunbeam in our rooms, and nothing daunted by the difficulties, still seek to ascertain the means by which such fatal diseases are propagated—in what consists the morbific agent, and how they may be neutralised. Another exemplification of the extraordinary power of these corpuscles : as I have mentioned, is that from their minuteness not only do they swarm in every tissue of the caterpillar's body, but they also in the imago or moth, pass into the undeveloped eggs, so that we have absolutely a disease, which is not only contagious from one individual to another, but in the ova the lethal corpuscles are found. Here, again, may we not from this seek some analogical information in considering the remarkable contagious disease which causes so much misery to the individual, so many premature and early deaths, and so many deteriorations of the offspring. It is not unreasonable to presume that microzymes may here exist, as in the fluid of vaccinia, sheep pox, or glanders. M. Chauveau and Sanderson have shown that in the fluid of the vacccination vesicle certain particles exist, which are not diffusible, but are suspended and floating in the lymph ; these microzymes are so small as one-twenty-thousandth of an inch in diameter. We have seen already that germs half that size have been found to exist in solutions, and that the Panhistophyton of the silkworm is not only circulated in the blood, but is actually found incorporated with the contents of the ova. It may, therefore, be readily understood that particles, such as these microzymes, of the vaccination vesicle, may readily gain admission to the circulation, and so influence the system as to impress it permanently for life.

The doctrines of Biogenesis and Abiogenesis have had, and still have, their supporters; but whatever be their mode of propagation, the existence of such floating and living organisms is of great interest, and, if studied carefully, may furnish us with a further insight into the nature of contagious infection and hereditary transmission. The subject may well commend itself to your consideration.

A word now as to your hospital practice—that great field where you are to learn the business of your life—where you are brought face to face with disease and accidental injuries, and become conversant with the many and wonderful varieties of the ills of our flesh. The importance of hospital study and clinical study is increasing daily. For your own information and credit sake you must there seek constantly and assiduously for that practical information which alone can enable you hereafter in life to withstand disease to the face—to feel confidence in yourself and inspire your patient with confidence in you. How could you presume to undertake the care or safe conduct of a disease if you had practically been unacquainted with its form. You will, therefore, understand, gentlemen, that the course of study you have initiated, many of you to-day, is to be pursued steadily, and step by step. As students, your motto must be, "*Nihil per saltem.*" You must keep the goal you are determined to reach ever in view. You will master each department and branch of our art one by one, and so fit yourselves for the practice of a profession which has been the just pride and ambition of so many great and good men. Before long, I doubt not, that the testing of your information, and advance in professional knowledge, will be made more progressive even than now, and that a system of examination shall be adopted by this College, which will, I think, be more conducive to your equable and gradual training, ensuring at the same time a more close acquaintance with the special departments to which your attention is directed, which are so essential to the more perfect practice of your profession. Having become members of that Profession, you will ever remember, gentlemen, to support its honour, its dignity, and its truth, in such a manner as will best become those whose privilege it is to be concerned about the tenement of the Divine anima ; who have sought to investigate the mysteries of the body, made after the image of the Omnipotent Creator, and who are the frequent witnesses of the final and solemn liberation of the sempiternal spirit from "the body of this death." You will ever keep in view the good of your fellow man and your country's. You will remember that the great object of our investigations is *truth*. All the success of our researches and our labours depend on it. The sentiment uttered by the great and admirable moralist, so many years since, to us happily applies—

"Still in thy right hand carry gentle peace
To silence envious tongues—
Be just and fear not—
Let all the ends thou aims't at be thy country's—thy God's and truths."

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS, EDINBURGH.—INTRODUCTORY ADDRESS IN THE MEDICAL AND SURGICAL SCHOOL.

By Dr. Joseph Bell.

After congratulating the students on their choice of a school of medicine, Dr. Joseph Bell said :—Edinburgh had for centuries been a noted centre of education, and for nearly 200 years unrivalled in the world as a Medical School.

The explanation of this undoubted fact might possibly be that the proverbial industry and perseverence of Scotchmen had given Edinburgh many hard working and accomplished professors; but he believed the main reason was because it consisted of two rival or apparently rival but really co-operating schools, which were so near each other as practically to be under the same roof. He referred to the losses of the University. Simpson, the versatile, many-sided, many-counselled, shifty man, whose never-resting, inexhaustible brain found relaxation in change of labour. Full of expedients, eminently helpful, loveable, and winning; inventive almost to a fault, yet still eminently practical; one who could not only use his own brains, but show others how to use theirs—the difficulty with him was to believe that he was one, not legion. He was Ulysses in his travels, and his shifts; Marquis of Worcester in his century of inventions; Captain Grose in his love for antiquities; a voluminous author, the best of nurses, a noted pamphleteer, besides in the intervals conducting probably the largest practice ever attempted by one man in Scotland. It would be many years before Edinburgh, Scotland, and the world even recognised what a loss that was when Simpson died. How could he trust himself to speak of Syme, the grave, honest, manly gentleman—the man who had done more for surgery, had been favoured to make more actual improvements than any other man who ever lived?—the teacher who somehow or other taught his pupils what they wanted to know, not by fluent oratory or eloquence, but by a sledge-hammer directness, brevity, and pith; the faithful friend, the fearless foe—his death was not only a public misfortune, but to many of those present a personal affliction. Dr. Bell then referred to the profession the students had chosen, and, in the first place, said he believed that many of them were unfit to begin the study of medicine as they ought, owing to the previous misdirection of their studies. He did not disparage properly-directed classical studies, but he did think the devotion of the student's whole energies from the age of ten to seventeen, wading through Latin poets or Greek prose, with intentions of making nonsense verses and getting up the loves of the gods and the murders of heroes, did not train the mind for medical studies. Anatomy they must know, and also the first principles of chemistry, if they wished to escape the accusation of pouring drugs, of which they knew little, into a body of which they knew less. The importance of a knowledge of physiology could not be over-estimated, but he was unable to see that botany and natural history were "necessary" parts of a medical curriculum. Medicine and surgery must be taught in the lecture-room but learned at the bedside. The pathology they read and heard of, and watched in the sick man's sufferings must be followed to the *post-mortem* theatre and verified or corrected there. They must study therapeutics: the actions and uses of remedies, and they must thoroughly master dietetics. The kitchen range was a far more important agent than the druggist's shop; the cookery book quite as worthy of study as the pharmacopœia. He could not see the use of stuffing students' heads with such pernicious absurdities as the colour, taste, smell and appearance of drugs, the tests of their purity, habitât, origin, price, and adulterations. The student must learn the use of his hands and also of his tools; also a little optics and acoustics. In a word, a well-educated medical man must emulate the versatility of the Admirable Crichton, the observation of Aristotle, and the inductive powers of a Bacon. Dr. Bell concluded by referring to the manner in which medical gentlemen should conduct themselves in their relations with their patients and others.

THIS evening, the 23rd, Dr. De Berdt Hovell will bring forward his views "On Hysteria," at the Hunterian Society. Members of the Profession are invited to attend and take part in the discussion. The Society meets at the London Institution, Finsbury Circus, at eight p.m.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XIII.

PRECIPITATION OF SEWAGE WITH CAUSTIC LIME.

AT first the patentees of this process were so sanguine of commercial success, and entertained such extravagant opinions of the fertilising power of the dried sewage precipitate, which they called "sewage guano," that great and unnecessary expense was encountered in the construction of the works at Tottenham and Leicester. They were built, in fact, with a view to commercial profit rather than for sanitary purposes; and, therefore, as soon as it was found, from experience, that the manufactured product had little or no agricultural value, and that the undertaking was unprofitable, the works were abandoned by the patentees, and transferred to the local authorities. In the case of Tottenham, the machinery and plant erected at great cost by Mr. Higgs were purchased at an almost nominal price by the local board, who could, therefore, have well afforded to use them properly for sanitary purposes; but instead of this, although ample proof had been furnished of their sanitary capabilities (as witnessed by the testimonial of the Board to Mr. Higgs in the month of February, 1857), yet they were so neglected and improperly managed as to have become at last a mere pretence of the objects for which they were designed and employed. The contrast, indeed, between the condition of things in 1857, as described in the testimonial of the Board, and subsequently, was most marked; for at that time, to use the language of the testimonial, "the supernatant water was discharged in a comparatively pure state into the river," so that "the Board, by these means, was able satisfactorily to sewer and drain their populous district, and dispose of the sewage without annoyance to anyone." Almost as soon, however, as the works had passed into the hands of the local authority, the process was so imperfectly conducted that the trustees of the River Lea were obliged to commence legal proceedings on account of the pollution of the river, and the nuisance created by the discharge of foul undefæcated sewage from the works; and this at last became so serious that an injunction was obtained to prohibit the offensive practice of the Board. In this manner the local authority became involved in expensive litigation, which might not only have been altogether avoided, but which, by being avoided, would have cost far less of the public money.

At Leicester, the sewage works, which were erected by the patentee and his company at a charge of from £30,000 to £40,000, were handed over to the local authority, according to the original agreement, free of cost; and from that time (1858) until now they have been used for sanitary purposes. At first they were

managed with considerable success, so that the River Soar, which receives the defæcated sewage water, was maintained in a wholesome condition; but lately the process has been seriously neglected, and the river is fast becoming as foul as it was before the works were erected. At the close of the year 1867, when we last visited the place, the operations at the works were as follows:—The City of Leicester, which is well sewered and drained, had a population of about 90,000 persons, and the water supply was from twenty-five to thirty gallons per head daily. The sewage, therefore, ought not to have exceeded three millions of gallons per day, but in reality it amounted to from four to five millions of gallons a day, so that it was evidently much diluted with subsoil water. The main sewer conveys the whole of the sewage to the works in the Abbey Meadows, which are on the bank of the River Soar, about half-a-mile from the town. On reaching the works the sewage is discharged into a well, from which it is lifted to a height of fifteen feet by two Cornish engines, each of 25-horse power, working night and day, according to the rate of flow. Each stroke of the pumps also delivers a graduated quantity of cream of lime, which mixes with the sewage in the channel into which it is pumped. It then passes into a trough about forty-five feet long, where it is violently agitated by means of revolving stirrers extending the whole length of the trough. This flocculates the precipitate occasioned by the chemical action of the lime upon the sewage, and so facilitates the subsidence of all suspended matters. It then flows into two subsiding tanks each sixty feet long and forty-five wide, having a shelving bottom which slopes from a depth of four feet at the sides to seventeen feet in the middle, where there is a channel or gutter with an Archimedian screw-race thirty-two inches in diameter, leading to a well provided with a Jacob's ladder of endless buckets. Here the great bulk of sedimentary matter is deposited, and the supernatant water flows over a cross weir into two other subsiding tanks, which are 120 feet long and forty-five feet wide, the bottoms being, as in the last case, on a lateral incline which slopes from a depth of six feet at the sides to nine feet in the middle, where there is a gutter that leads into the channel just mentioned. These tanks are covered; and the defæcated sewage leaves them by a shallow weir, about three-quarters of an inch below the surface, and falls into the main channel, which conveys it to the river. The total time of flow in the tanks is about four hours, and the lime was said to be used in the proportion of one ton per million gallons of sewage—that is, at the rate of 15·68 grains per gallon, but there is good reason for believing that this quantity was not actually being used. The main depositing tanks are worked alternately for about three weeks or a month, when the sewage is diverted, and the consolidated precipitate is driven forward to the well by the Archimedian screw, which rotates in the centre channel of the tank, and it is thence drawn up by the Jacob's ladder and discharged into a shoot which conveys it to the outside pits, where it drains and consolidates. The covered tanks continue in operation for about three months, when the sludge is scraped into the screw channel and so removed. The precipitated matter is exposed to the air in large quantity for a considerable time before it is sufficiently consolidated to sell for manure; and even then it contains from 30 to 40 per cent. of water.

The following was the composition of the sewage before and after this treatment:—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	60·33	48·33
Organic matter . . .	8·50	4·68
Ammonia	2·236	1·471
Ditto organic . . .	0·160	0·120
Nitrogen as nitrates . .	0·025	0·193
Oxygen required to oxydise .	0·969	0·750
Matters in suspension . . .	11·45	4·54
Organic matters . . .	6·63	0·63
Mineral ditto . . .	4·82	3·91

The matters precipitated from the sewage by the lime, together with the carbonate of lime so formed, amounted to 36·72 grains per gallon, of which 14·93 were organic, and 22·39 mineral. This shows that the lime was not being used at the time of our visit in the estimated quantity of 15·68 grains per gallon of sewage, as this would have produced at least 32·82 grains of mineral matter. The precipitate has been frequently analysed, and it generally contains in its dry state from one-third to nearly half its weight of organic matter, with about 2·5 per cent. of phosphate of lime, and about 1 per cent. of nitrogen, capable of yielding about 1·21 per cent. of ammonia. The value of the manure has been variously estimated by agricultural chemists at from 13s. 6d. to 17s. per ton; but the price realised at the works is only about 1s. a load. In its dry state, however, a good deal of it is sold to manure makers for 7s. 6d. per ton. The annual cost of conducting the works is about £1,400 a-year, of which £400 is returned to the Corporation by the sale of manure. This loss, which is inconsiderable in a sanitary point of view, and which might be much diminished by proper management, has led to greater and greater neglect in the conduct of the works, until now, as we are informed, the sewage is so imperfectly defæcated that the river is fast becoming as foul as it was in 1855, when the works were established by Mr. Wicksteed; and it is not unlikely that the foul condition of the river may be wrongly attributed to a failure of the lime process, *per se*, rather than to the carelessness and false economy of those who have had the management of it.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

DUST AS A FERMENT.

By Charles R. C. Tichborne, F.C.S., M.R.I.A.,
Chemist to the Apothecaries' Hall of Ireland, &c.

The celebrated lecture and papers upon "Atmospheric Dust," published last year by Professor Tyndall, brought prominently before the public a subject which is intimately connected with the one which I have taken for my text on this occasion, and which for many years I have looked upon as one of our most fertile sources of disease in large towns, having, in 1866, when the cholera was raging in Dublin, drawn attention to the dangerous character of our street dust.

It is, however, my intention, in the present paper, to place simply on record some experiments which have been performed from time to time which bear upon this most important subject.

Metropolitan towns are unfortunately those which, as a rule, suffer most from zymotic diseases, for the accumulations in a town of importance bring their attendant ills. Every acre of buildings, and every increase in population, bring irremovable dirt. The vitiation of localities is not merely a matter of the numerical proportion of the inhabitants, but it becomes changed in character and more dangerous from the destruction of the numerous compensators or renovators provided by nature. The population seek suburban dwellings, and expend fabulous sums in the extra expenses incurred thereby. Those who are forced to remain in the seething mass are, but too frequently, those who suffer most from this dirt, and who, from their careless habits of living tend most towards its advancement.

A good supply of water has been insisted upon for many years, and sanitary measures have been taken in most large towns in regard to this important subject. The gaseous condition of the atmosphere has also received some considerable attention, particularly in connection with the effects produced by manufactories. I cannot help thinking that, as regards epidemic diseases at least, the influence of these sources of contamination has been a little exaggerated, except in the cases of a few of the direct blood-poisoners, such as sulphuretted hydrogen. A most important substance, however, in connection with our sanitary condition, is what has been termed "Atmospheric Dust," or the floating solid constituents of our air. Although well known, it was not much investigated from a scientific point of view in this country until Dr. Tyndall, Professor Lister, and a few others drew attention to it. Tyndall in his experiments has demonstrated, however, one important point, namely, that this "Atmospheric Dust" may be viewed as organic matter. But its proximate analysis is one of extreme difficulty, and the researches which have been made in this direction do not throw much light upon the subject. Dr. Angus Smith has, however, with great perseverance, worked out some valuable facts, bearing upon this part of the investigation.

It is evident from the difficulty in giving a critical examination of atmospheric dust that the point of enquiry tends more in the direction of the local pabulum of these particles, and here it may be as well to state I strictly confine the term atmospheric dust to that dust which floats at a certain altitude, and which has been winnowed from the inorganic particles, if we except small traces of sodium that are not worth consideration. It is this organic portion that contains the germs which, if not absolutely essential to all changes coming under the names of fermentation and putrefaction, are the prime movers in such phenomena. As Professor Lister says: —"The sporules, besides being produced in incalculable multitudes, are of extreme minuteness, and constitute a very fine dust, which cannot fail to be wafted and extensively diffused through the air." "The particles of dust which are rendered visible to the eye by being illuminated are gross compared with the sporules of a fungus."

As regards much of the pabulum of the atmospheric ferments and the ferment itself, it lies on our shelves, floors, and streets. This is the nest in which germinal matter is fostered and wafted through our atmosphere. Each dust must partake more or less of the local condition of the place.*

The following paper is written with a view to give the analyses of some of the dusts, which, to a certain extent, may be considered as typical; also to determine as far as possible their chemical activity as ferments, or their adaptability to become ferments.

Street Dust.

The two following samples were taken from our principal streets, both of which are paved with a very hard and non-absorbent stone.

Grafton Street Dust, dried at 100 deg. C.

(Containing nitrogen, 2·1) - - -	
	100·0

* Dr. Percy says that the Library of the British Museum gives a dust having 50 per cent. of organic matter in it. ("Dust and Disease," page 4.)

The organic matter in both these dusts consisted of stable manure finely ground; a glass of very low power was all that was necessary to prove this fact, but part of it, from its minute state of division, was evidently very old.

Nassau Street Dust was taken from the locality of a cab stand, and the organic matter was here in an incipient state of change; it exhibited traces of ammonia, whilst dusts as a rule generally give, if anything, a slightly acid reaction. Street dust, then, consists of stable manure and stone finely ground; the traffic supplying the grinding power. On a macadamised road, irrespective of the effects of the traffic, the inorganic matter greatly preponderates, and as it is soil with which the animal matter is attenuated, the mischief is at its minimum. Not so as regards the streets of large municipal boroughs, which are generally paved with a hard stone, which would have no other effect upon this substance than that of an attenuator.

Dust taken from the Top Seats at Merrion Hall, Dublin.

Organic matter - -	32·1
Inorganic matter - -	67·9
	100·0

Dust from Gallery of the Theatre Royal, Dublin.

Organic matter - -	53·2
Inorganic matter - -	46·8
	100·0

Dust from the Ventilatory Space above the Gas in Ancient Concert Room, Dublin.

Organic matter - -	35·7
Inorganic matter - -	64·3
	100·0

These three last specimens as regards general appearance resemble each other considerably. Merrion Hall is the largest place of worship in Dublin, and is comparatively a new building. The other two buildings are much older. The Theatre we presume receives a much greater number of visitors in the course of the tenanted months. All these buildings are well ventilated. The large amount of iron in such dust is peculiar; for instance, that obtained from the Ancient Concert Rooms gave twenty-one per cent as the amount of peroxide in the inorganic matter. This is probably due to a slow combustion of the gas burner.

Dust from the Walls at the Top of Nelson's Pillar, Sackville Street, Dublin.

Organic matter - -	29·7
Inorganic matter - -	70·3
	100·0

Height, 134 feet.

This monument is built of granite, and the residue of inorganic matter in this case, consisted of mica felspar, &c. If we take into consideration the position and the difficulty in not detaching a considerable quantity of stone, although a feather was used, the amount of organic matter was truly extraordinary, and if we put it down as containing over fifty per cent. of organic matter (as actually contained in the dust if it could have been removed by itself), we shall not be far off the mark.

Some further experiments were then instituted to determine how far, and to what extent, these dusts would operate as ferments, and a volumetric system of measuring the intensity of any process of fermentation was contrived. It enables the operator to watch the process much more definitely than he could by ordinary observation. The process is based upon the reduction of the nitrate of any base to a nitrite in the presence of substances undergoing putrefactive fermentation. In these experiments the following precautionary measures were adopted, so that, as far as possible, all the fermentations induced were proper to the ferments used in the experiments.

Distilled water was taken and permanganate of potassium added until a distinct red colour remained, it was then distilled, the first portion being rejected. The remainder was then used for the experiments. The ashes of yeast may be employed to supply the mineral ingredients, but in these experiments a mixture of nitrate of potassium, phosphate of sodium, and a little sulphate of potassium, and chalk to neutralise the acids formed were employed, the pabulum used being a mixture of cane and milk sugar. The mixtures were

well boiled in each experiment in their respective flasks, and after closing with cotton wool and cooling, the ferments were added. They were all placed in a similar position and submitted to a pretty constant temperature night and day, varying from twenty deg., to twenty-eight deg., C.

Expt. 1.—In this case the above mixture, which was found by experience to be one easily convertible into lactate of calcium in the presence of ferments, was submitted for some two or three weeks to the temperature conducive to such changes. It showed no decomposition for fourteen days, but at the expiration of that time there were indications of a fresh molecular arrangement, but no particular development of organisms. This evidently showed that the precautionary method taken for the destruction of the germinal matter had more or less been perfect. The opening and closing of the flask would more than account for the change evinced.

Expt. 2.—In this case ¼ of a grain of nitrate of potassium was used to the fluid ounce of the fermentable mixture. The ferment was the mould of cheese. It was examined from day to day in the following manner:—5 c.c. of the clear liquid were withdrawn with a graduated pipette, and the level of the remaining liquid marked on the flask, so that it can be made up to the original level if there is any loss from evaporation. The 5 c.c. were then mixed with a little mucilage of starch and iodide of potassium added. On acidulating with sulphuric acid, blue iodide of starch was at once formed, representing the $N_2 O_3$ present. A volumetric solution of hyposulphite of sodium was then added until decolourisation of the iodide of starch took place. Each degree of hyposulphite consumed would represent 0·28 of a grain of nitrate as being reduced to nitrite.

	Nitrites.	Nitrates.	Remarks.
After the 1st 24 hours	0·5 hyposulphite consumed.	Present.	Fermenting slowly.
,, 2nd 24 hours	Trace.	Present.	Increased fermentation.
,, 3rd 24 hours	None.	Present.	Vigorous fermentation, thick mycelium, and great quantity of spores.

In seven days the liquid had become thick with the mycelium, and crusts of lactate of calcium began to form; in forty-eight hours afterwards the contents of the vessel were solid.

This experiment was repeated again, but with three grains of nitrate of potassium to the fluid ounce the results were different, for in this case nitrites were present during the whole of the fermentation. This is rather a curious observation, for although the entire of the nitrates was not destroyed; in the first instance we had little or no evidence of the nitrous acid. It is probable that in the reduction of the nitrates preparatory to the assimilation of its nitrogen, a nitrite is the first stage, but that if the ferment bears a considerable proportion to the nitrate present, the nitrogen will be assimilation in the form of some lower compound of nitrogen. There is no evidence of the molecule $N_2 O_3$ during the fermentation, although the supernatant fluid is always slightly acid. One point of importance is evident that, in the examination of potable waters, if no nitrates are present, it is no proof that decomposition is not actually proceeding at the time as regards the organic matter therein.

Expt. 3.—Street dust was allowed to remain some time at a temperature of 20 deg., to 28 deg., C.; it became after a little while covered with a thick mould. This mould acts as a ferment of great activity when placed in the saccharine mixture described above. After being partially dried it seemed more active, weight for weight, than the mould from rotten cheese.

The following results were obtained on fermenting the usual solutions of sugar, &c., with the addition of three grains of nitrate of potassium, and sufficient street dust to represent 1-2000th part of the sugar. (In adding this and the other dusts as ferments, only the organic portion was taken into consideration, the weighing being regulated accordingly.)

Days.	Degrees of volumetric solution of hyposulphite of sodium required to decolourise the iodide of starch from the liberated $N_2 O_3$ in 5 c.c.	Remarks.
2	0·3	
3	3·5	Spores, &c., considerably developed.
4	9·5	Fermentation very active; beautiful mass of mycelium.
5	8·0	Fermentation going on very actively.
6	8·5	Fermentation very strong, large quantity of carbonic acid given off, and thick layers of mycelium on the surface.
7, 8, and 9	8·5, 7, and 9·5	Fermentation on the decline.
10 and 11	1	Liquid had become very thick and crusts of lactate of calcium beginning to form.

Expt. 4.—Was a similar examination of the activity of the dust obtained from Nelson's Pillar, a monument in Dublin, 1-2000th part being used.

Days.	Degrees of volumetric solution used.	Remarks.
2	3·5	Thick coating of mycelium at once formed.
3 and 4	4 and 7	Fermentation going on vigorously.
6 and 7	8·5 and 8·5	Fermentation seemed upon the decline.
10		Quite solid from lactate of calcium; vessels could be inverted without contents falling out.

Expt. 5.—The dust from the Ancient Concert Rooms was obtained from the ventilating space above the public room. This, it will be remembered, contained a considerable percentage of iron.

Days.	Degrees of volumetric solution.	Remarks.
2	trace of nitrite	No perceptible sign of fermentation.
3	1·0	Slight sign of fermentation.
4	3·5	
5	9·0	
7	10·0	
8 and 9	10·0	Fermentation seemed on the decline.
10	8·5	
12	4·0	Lactate of calcium began to form slowly.

Expts. 6 and 7 were, respectively, with dust from the Theatre Royal and Merrion Hall, Dublin. The first was almost exactly similar to the fifth experiment, but the dust from Merrion Hall approached more nearly to the fourth experiment in its results.

In conclusion, I may remark that, although if I had had time to repeat these experiments, many points in the details of manipulation would have been improved, still the results are of some importance.

They conclusively prove the power of dust as an active ferment.* Also the estimation of the $N_2 O_3$ as a criterion of the extent, or intensity, of such an action is, I believe, capable of further development. Thus, a slight fermentation that would not probably be perceived could not escape observation by this method. These experiments, as far as they go, seem to point to a curious phase of the subject—that is, that dust taken at a great height, and in such a position as in the fourth experiment, should appear to have as great, or greater, activity than that which would be obtained from a building which is nightly crowded to suffocation. This, in some measure, may be due to the extreme levity of the spores, which are supposed to be the life of the dust, and which lightness may be described as almost approaching volatility. *There is, probably, an altitude of the maximum of activity for all localities as regards dust.* Dust still is so light that even that obtained in an ordinary house contains a large portion that refuses to sink when thrown upon water; and, even when the vessel is placed beneath an air-pump, a large percentage still

* If it is required to manufacture butyrate or lactate of calcium practically, I would never advise the use of cheese as a ferment, if any active dust could be got (I do not think there will be any difficulty as regards this point); to get rid of the quantity of extraneous matter which is introduced by the cheese, is frequently very difficult. A little dust, separated from the coarser particles by elutriation, is the correct ferment.

floats. To me the activity of the dust taken from the top of the monument 134 feet high is something marvellous—this source so far removed from the busy streets—yet its organic matter contains what is capable of splitting up, in a short time, hundreds of times its own weight.

I am aware that the results obtained, and detailed in this paper, are not so elaborate as I should wish, but they are experiments in which time is an important item; they are, however, quite sufficient to prove the value of such investigations. Microscopy, at present, is not likely to throw much light upon this subject, except in conjunction with some such work as detailed in the present paper.

Transactions of Societies.

THE MEDICAL SOCIETY OF LONDON.

November 14th, 1870.

John Gay, Esq., F.R.C.S., President, in the Chair.

The President exhibited

SOME TRANSPARENT ELASTIC TISSUE, OILED SILK, AND GUTTA PERCHA, FOR DRESSING PURPOSES.

These were not to be affected by heat or moisture, and can be washed and used again.

Dr. Althaus brought forward a girl, aged sixteen years, who had rheumatic symptoms in 1870, followed by paralysis of right arm, sensation and motion were alike lost, but there was no atrophy of the limb nor change of temperature. The interrupted current had no effect on the arm, but the continuous current was followed by muscular contraction, and sensation was restored after four applications; in three weeks she was able to move her wrist; the progress of cure ceased when the treatment was suspended on the girl going into the country; but on the treatment being renewed, a cure resulted which the Fellows could observe. It might be noted here, how the muscular paralysis was not affected by the interrupted current, there was one point against the cerebral origin of the paralysis, its gradual cessation and limitation were also against cerebral origin, absence of paralysis of the intercostal muscles was against its being a spinal paralysis. There was no evidence of hysteria or of lead poisoning, and the absence of nutritive change was against paralysis of the cervical sympathetic. Dr. Althaus believes the paralysis to be quite a rheumatic affection of the right bronchial plexus.

Dr. Wiltshire had seen this case at the West London Hospital. He treated the patient with alkalies, iodide of potassium, and nux vomica, but no medicine did any good, and he sent the girl to Dr. Althaus at the Infirmary for Paralysis where she was cured.

Dr. Althaus then showed a very neat and portable machine made by Caiffe of Paris, for applying the interrupted current; also he showed a battery of fifty cells of zinc and platinum, for applying the continued current. This battery was contained in a box, and when closed, the plates were kept free from contact in vulcanite cells below. By opening the lid fully the cells were raised, and the liquid being thus brought in contact with the cells, action of the battery commenced. The battery was very durable, and gave off no noxious fumes, it was made by Weiss, of the Strand.

Mr. Teevan then showed

A CALCULUS THE SIZE OF AN ALMOND,

which he had removed from the ischio-rectal fossa of a patient at St. Peter's Hospital. The man was forty, and had been cut for stone when he was five years old, recently he had suffered from an escape of urine from the cicatrix, and, on examination, Mr. Teevan found a hard body which he removed by incision, and which proved to be a calculus having facets, so that doubtless it had been at one time in contact with other calculi in the bladder.

The President then showed a calculus which he had removed from the bladder of a very ricketty boy, twelve and a-half years old, it weighed two and a-quarter ounces. He performed the operation a few weeks back, and found it very difficult, owing to the contracted state of the pelvis, the lad was very feeble, and sank some days after the operation.

Mr. John Daniel Hill then read the paper of the evening,

AN ANALYSIS OF 140 CASES OF URINARY STRICTURE, TWENTY OF WHICH HAD BEEN SUBMITTED TO SYME'S OPERATION OF PERINEAL SECTION, AND 120 TO HOLT'S OPERATION OF FORCIBLE DILATATION.

The cases were classified, as—1st. Cases of single stricture; 2nd. Cases of multiple stricture; 3rd. Cases of complicated stricture. In these three classes Holt's operation was performed; the fourth class comprises cases of cartilaginous non-dilatable stricture, usually the result of injury, and these were treated by perineal section. The strictures were discovered as nodular and bead-like to the touch, or as fusiform and elongated. Sixty-nine cases of stricture on the bulbo-membraneous portion of the urethra were cured by Holt's operation; thirty-one cases of multiple stricture were also cured by the same operation. In the 120 cases, there were but two deaths to set aginst the 118 cases, and these took place from congestive pneumonia. The bladder, urethra, and kidneys of one of these fatal cases, were shown to the Fellows, they could see that no laceration had taken place where the stricture had been split by the instrument. The patients were usually discharged at the end of a week or ten days, with instructions to pass a No. 11 catheter occasionally. Cases where no instrument could be got through the strictures as well as those of stricture, where the passage of an instrument was followed by rigors, were treated after Syme's plan of perineal section; the loss of blood was small in the operation, and rarely did any unhealthy action occur in the wound; if there was any relapse, a second operation was performed. Mr. Hill laid great stress on preparatory treatment.

Mr. Barnard Holt said, that he did not desire to say much on the first class of cases, they were simple and easily cured by his operation, the real value of the operation was proved in cases that had been condemned as incurable, and he instanced the case of an officer from India, who had come under his care with stricture and fistula in the perineum, the buttock, the groin, and who had to set over a large pan whenever he made water, as it came from him as from a watering pot; this man's stricture was split, the fistula gradually treated and he got quite well. In another case, the patient was seventy-six years old, and for years he had laboured under a stricture, which was so tight that no instrument could be introduced; by accident, however, Mr. Holt was enabled to pass a very small instrument, and was then able to split the stricture; in three days the patient was enabled to go into the country relieved of his stricture. Mr. Holt considered his operation applicable in all cases where an instrument could be got through, but it was hazardous in cases when the kidneys were diseased. He very nearly lost a patient who had fatty heart and diseased kidneys after he had operated upon him. The man had a very dense stricture, and after it had been operated on he had a rigor, next day he was cold and pulseless, and the secretion of urine had ceased, it was only by great care that he was brought out of his precarious state, as for some time he had all the symptoms of uræmic poisoning. The ultimate results of the operation were good as when Mr. Holt's directions were followed, relapse never took place, and he believed from the few opportunities he had of making *post-mortem* examinations, that in his operation the mucous membrane was not torn, hence their never is infiltration of urine. Mr. Holt never leaves the catheter in the bladder, except in cases of traumatic stricture.

Mr. Teevan said, that he and his colleague Mr. Coulson, had treated more than a 1,000 cases of stricture in St. Peter's Hospital. He preferred the French method of gradual dilatation, by the bougie Olivain as used by Mercier. With this operation a bad result never occurred, and the cure was usually complete in from six weeks to two months' time. He alluded to a paper read by him on stricture at the British Medical Association at Leeds, and in the discussion there, Mr. Stokes, jun., said, that he had seen cases of rupture of the mucous membrane after the splitting operation. After fourteen days, such a rupture of mucous membrane would probably have healed, and so not be found at a *post-mortem* examination made at such a distance of time from the operation.

Mr. Hill in reply, said that with due care he did not think laceration of the mucous membrane need occur.

Yellow-fever is still prevalent at Barcelona. Letters describe the town as quite deserted. Camps are being formed up the mountains—a very wise plan.

ROYAL MEDICAL AND CHIRURGICL SOCIETY.

1st Meeting, November 8th, 1870

Dr. Burrows, F.R.S., President, in the Chair.

A paper was read on the

ELECTROLYTIC TREATMENT OF HYDATID TUMOURS OF THE LIVER.

By Dr. Hilton Fagge, and Mr. Arthur E. Durham.

Based upon eight cases of hydatid disease of the liver successfully treated by electrolysis. The authors believe that this method of treatment has not hitherto been adopted in any other case of the same nature in the human subject.

The operation was performed in the manner recommended by Dr. Althaus in his treatise "On the Electrolytic Treatment of Tumours." In each case two needles were passed into the tumour, and were connected with the negative pole of a modified Daniell's battery of ten cells. The positive pole, terminating in a moistened sponge, was placed upon the surface of the abdomen. The current was allowed to pass for a period varying from ten to twenty minutes, in different cases. The needles were then withdrawn. A little clear fluid in some cases appeared at the seat of the puncture.

No preliminary tapping nor exploratory puncture was made in any case. The diagnosis rested on the facts that the patient had a rounded, elastic tumour projecting from the liver, and that this was *cystic*, as proved by the needles rubbing freely against one another in its interior, although introduced an inch or two apart.

The operation was followed in most cases by rapid diminution of the tumour, which even shortly after the operation became soft and flaccid. At the same time, in some cases, fluctuation became perceptible in the lower part of the abdomen. The authors believe that some of the hydatid fluid probably escaped through the punctures made by the needles, having been possibly forced out by the accumulation of hydrogen gas in the interior of the cyst. The success of the operation would thus appear to depend, not on the direct action of the electric current, but on its effecting, as it were, a kind of subcutaneous tapping; and they suggest that simple acupuncture might possibly be followed by equally successful results.

Slight febrile symptoms, and more or less pain, in most cases followed the operation; these symptoms, however, rarely lasted more than three or four days. In one instance they were entirely absent. In most cases the patients were able to get about in a few days, and some of them were discharged from the hospital at the end of two or three weeks. Even at this early period the tumour had already, in some cases, very manifestly decreased in size; and, as a rule, this decrease, when once it had fairly commenced, steadily progressed. After the lapse of six months or a year, when each patient returned for examination, no trace of the diseased remained; or, at most, there was only some ill-defined fulness of the epigastrium.

In one case only the result still remained doubtful. In the remaining seven cases the favourable issue above described had already taken place. All the patients were in perfect health. In each of them the tumour had been large, and in at least one instance it had reached quite unusual dimensions. In three cases more than one cyst existed, and each cyst had then to be electrolysed separately. In the latter part of the paper the results of electrolysis are compared with those of simple tapping—the operation which has hitherto been most successful in the cure of hydatid disease of the liver. The authors claim for electrolysis that it rivals simple tapping in being unattended by immediate danger to the life of the patient, and that it is to be preferred, inasmuch as (according to their experience up to the present time) it involves no danger of suppuration within the cyst, and consequent risk and suffering—results which often follow simple tapping. The authors conclude their communication by referring to a case in which Dr. Playfair, in accordance with their suggestion, treated an hydatid tumour of the liver by simple acupuncture. The results of this case promised to be favourable; but as yet sufficient time had not elapsed to warrant any decided expression of opinion.

Dr. Robert Lee had met a case four years ago. The patient, a lady from Calcutta, had an abdominal swelling which was said to be ovarian, and she was sent home for operation. By chance she consulted him, and he diagnosed pregnancy. Another, however, diagnosed hydatid tumour of the liver, and recommended puncture. The case went on, and she was delivered; but a tumour was left behind which was still pronounced to be ovarian. Puncture caused it to shrink, and it did not recur.

Mr. Hulke said that years ago Dr. Budd had tapped a hydatid cyst, but only a few drops of fluid came away. Some years after the woman died in childbirth, and a shrunken cyst was discovered.

Mr. Barwell asked why two needles were employed, and why they were connected with the negative pole.

Dr. Althaus was glad to find that his suggestion had turned out well, as the treatment by tapping had not been very successful. If electricity was not required, it was good that acupuncture should be employed. Two needles were employed to extend the disengaging surface, and the negative pole was used as developing hydrogen, not oxygen.

Dr. Murchison said it would seem that fluid had escaped from the cyst, and yet no bad action had been set up. Was it advisable to allow the fluid to percolate into the peritoneum, or to allow it to escape? Suppuration generally followed secondary enlargement after tapping. This enlargement generally subsided of itself, The entry of air into the cyst depended on the care taken in tapping, and the use of the aspirator would prevent its entrance.

The authors replied briefly.

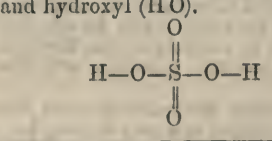
Literature.

LECTURE NOTES FOR CHEMICAL STUDENTS.*

Some six years ago, Dr. Frankland published the first edition of his Lecture-Notes. The work was very favourably received by this and other periodicals at the time, and although it is a work which must be limited in a certain degree as regards its sphere of usefulness, it has been found necessary to issue another edition. In its general character it differs very little from the original form. The book consists of notes to the Course of Lectures delivered at the College of Chemistry during the winter session. "It contains no description of properties of the bodies, but mainly consists of reactions or decompositions illustrated by graphic notation and glyptic formulæ." One of the chief changes is that it is divided into inorganic and organic chemistry, each being published in a separate volume. However unphilosophical such a division may seem, we suppose the author has some good reason for making this division for the sake of convenience in study, for we are told that it has been done at the request of numerous readers.

In the original edition, the graphic notation adopted is modified in the present by the omission of circles surrounding the symbols of elements. Dr. Frankland's book is now so well known that it seems almost superfluous to enter into details about it. He divides and groups the elements as having monad, diad, triad, tetrad, and hexad molecules, and again subdivides them into sections, containing those more closely allied in chemical character. The Greek prefixes representing their quantivalence towards the other molecules. The principal peculiarity of these Lecture Notes is the use, all through Prof. Frankland's formulæ, of thick symbols to indicate that the elements represented by the first symbol of a formula is directly united with all the active bonds of the other elements, or compound radicals following upon the same line. Such thick letter would occupy the centre of a graphic formula thus :—

S O_2 H O_2 sulphuric acid signifies that the hexad atom of sulphur is combined with the four bonds of two atoms of oxygen and hydroxyl (H O).



* Lecture Notes for Chemical Students. By Ed. Frankland, F.R.S. &c. Vol. I., Inorganic Chemistry. Second edition. London: J. Van Voorst. 1870.

In the above notation, H o_2 means $H_2 O_2$ or $(H O)_2$ as it would be ordinarily written, and is called by Frankland hydroxyl. It is a supposed compound radical, and is familiarly known as peroxide of hydrogen.

We recommend these Lecture-Notes to the careful consideration of every student of chemistry that wishes to have more than a superficial notion of his science. The book is evidently a carefully considered attempt to methodically systematize the science of chemistry, or the molecular changes that take place in matter from the action of external force or other cause.

A MANUAL OF QUALITATIVE ANALYSIS.*

The chief additions to this well known work are as enumerated by the author in the Preface :—"1st. Bunsen's Flame Reactions; 2nd. The Detection of the Poisonous Metals and Acid Radicals in the presence of Organic Matters; and 3rd. Additional Tests for the Detection of the Individual Alkaloids, and more complete systematic method for the detection of these Bodies. The new notation has been adopted, and the division of the book into three chief parts, and the arrangement of these parts, will, I hope, be found to be an improvement."

In the text, the author redeems his pledge to the fullest extent, but we cannot help thinking that it is a pity that so good and useful a book, as Mr. Galloway's, should be marred by the egotistic view of the preface, and the uncalled for attacks upon works of world-wide fame. Progressive catechetical questions do not constitute such a novelty in teaching to warrant the author in saying, "That his work is not constructed on the bad system of the 'Giessen Outlines,' and some other analytical works, or on the system of Fresenius, which is quite as faulty and still more *impracticable for the learner*."

Although Mr. Galloway's book might, with some degree of justice, be compared to the "Giessen Outlines," it has very little in common with Fresenius; and we think that for quick teaching (*which for the sake of passing examinations* is now unfortunately so much in vogue) the manual before us might be even a more desirable book than those mentioned. A student enters a Government school with the intention of passing an excellent examination after devoting a few sessions to the study of a gigantic science, and he is generally successful in it if he has any amount of ability. But is this all? Do these young men represent those that in their day are to bear the heat and burthen of their respective sciences? We opine not. As regards the workers in science, the crammed-examination system has been an utter failure. It may have its bright side, but it does not face that way. Besides, why do not authors leave the marked superiority of their works to be discovered by the public. A preface may be synoptical, apologetical, or explanatory—but it should not be an advertisement.

At the end of this same preface, the author gives some excellent advice taken from Carlyle's address to the students of the University of Edinburgh. It is too long or we should be tempted to transfer it hither. It is appropriate to all students but particularly to the analyst. The remarks are worthy of being indited in letters of gold, and hung up in every school of science. "Be honest in all your enquiries" is his text, and a noble one it is. "More and more endeavour to do, think, and keep an accurate separation in your own minds of what you have really come to know, and what is still unknown."

The analysis of proximate animal substances is treated much more fully and artistically than is usually done. They are arranged into groups, consisting of compounds having properties in common. Thus, there is—1. The *Albuminoid Group*, consisting of albumen, fibrin, casein, globulin, vitellin; 2. *Gelatinous Group*, consisting of gelatin and chondrin; 3. *Sugars;* 4. *Alkaloids*, urea, creatinine, creatin; 5. *Acids*, lactic, hippuric, glycocholic, hyocholic, and taurocholic acids; 6. *Cystine, Xanthine, and Cholestrin;* 7. *Colouring Matters.* Then follows a method for analyzing animal secretions, including urine.

The extra amount of care devoted to the flame reactions is a special feature of this book, and renders it more valuable; but why does the author of a "Manual of Qualitative Analysis" ignore spectrum analysis?

Mr. Galloway's works on educational chemistry have all been successful, and deservedly so. His "Second Steps," which, by the bye, we believe, has not appeared yet in the form of a second edition, was a particularly "happy thought," and was a well conceived adventure in scientific book writing. We wish the fifth edition of the "Manual" the success of its *confrères.*

* A Manual of Qualitative Analysis. By Robert Galloway, F.C.S. 5th edition. J. Churchill and Sons. 1870.

DICTIONNAIRE DE CHIMIE.*

This dictionary still progresses in its original high-class tone. We are afraid that it will be some time before we receive a further instalment. We have in the present division an interesting monograph on *Dissociation*, of which subject we have, perhaps, no better notice extant. The work done in connection with it is probably collated here for the first time. We may mention also in particular, the following aricles: — *Densité*, containing drawings of the apparatus used in determining specific gravity of liquids and vapour densities; *Dialyse, Diffusion, Eau*, considered from its chemical and physical point of view. *Ebullition* is a very interesting article upon boiling points, in which it goes extensively into the boiling points in connection with their chemical composition; *Electricité, Engrais* (Manures), *Etain, Ethers*, and *Fer*—the last being profusely illustrated, and treated from its scientific and technical point of view.

* Dictionnaire de Chimie. Par Ad. Wartz. 8 et 9 Fascicules Cyanures—Fermentations. Libraire, P Hachette et Cie, Paris.

Stercoraceous Emanations as a Cause of Disease.

The agency of effluvia and of subterranean percolations from human feces, in producing various forms of disease, is considered by many medical writers as a well established fact. The odour of feces is reported in some cases to have given rise to severe endemics. Cholera is said to have been propagated in this way, and also by percolation from privies into wells at some distance, though the water may appear to be quite pure when tried both by sensible and chemical tests. This fecal theory is the best theory extant for strategic purposes. Wherever man is, feces must be near at hand; and a lively imagination can always trace the subtle poison rising in the air and entering the lungs, or sinking into the earth and impregnating the water of springs and wells, and thus reaching the human stomach. Take the following illustration, from no less a personage than Dr. Anstie: "A country town, without deep drainage, disposes of its sewage in cess-pools; and the limited space in which the houses stand renders it inevitable that the drinking wells should be within a very short distance of the cess-pools. From the latter a continual oozing of decomposing organic matter takes place, and more or less of this finds its way into these wells. For years possibly no particular harm can result. But at length there comes a long, dry summer, which reduces the water to a low ebb, and concentrates its impurities, besides favouring decomposition. In such circumstances typhoid fever breaks out among the persons who drink the water."

Now it so happens that this description applies exactly to the city of Oakland, and has applied to it every year since its existence; and yet there has never been a typhoid endemic in the place, while several sparsely settled rural districts in Alameda County, where the water of springs is used, which could by no possibility be impregnated with such impurities, have been frequently visited by that disease. It is worthy of note that no account is taken by Dr. Anstie of the "long, dry summer which reduces the water to a low ebb," as a climatic cause of disease. There is overlooked in his etiology only as

it affects the water; whereas, every one knows that just such summers are favourable to ordinary autumnal fevers in all malarious regions of country. According to our observation, typhoid and typho-malarial fevers prevail quite as much in California, in rural districts where fecal impurities of the water can not exist, as in towns where wells and cess-pools are in proximity. The towns, indeed, are more exempt than the country.

We never have had any faith in the fecal theory. We regard it as one of the bubbles of the day, which will disappear before many years, and return by-and-by, like a comet from its wanderings, to amuse a future generation of medical philosophers.—*Pacific Medical and Surgical Journal.*

ANOTHER MORAL PEST.

Work as christians and philanthropists may, in their endeavours to eradicate evil and raise the standard of morality, they seem on every hand, to be surrounded by unexpected enemies and forestalled by the agencies of wickedness. Sometimes we are protesting against the filth distributed in quack handbills; lately the advertisements of baby-farmers and similar monsters have excited public indignation; now we are desirous of directing attention to another evil, the extent of which can scarcely be measured, but the existence of which may transform the public schools of this country from blessings into curses.

We observed last week in the *Morning Post* and the *Times*, the following enigmatical advertisement which has since been repeated, and has also appeared in other journals:—

PRESENT and PAST PUBLIC SCHOOL BOYS are requested to DESIST from CORRESPONDING with FORMER SCHOOLFELLOWS, unless they will abstain from introducing into their letters topics which cannot be alluded to in the family circle.

What is the meaning of this singular appeal? We learn, upon inquiry, that some estimable people have discovered a practice that has, we fear, existed since the time of cheap postage, and they hope to curb it by an appeal of this kind—a hope we scarcely share, since the men who will thus endeavour to corrupt the minds of young persons can have little sense of honour to which to appeal.

There is, however, a more direct mode of putting a stop to the practice which, for the benefit of those who have just made this painful discovery, we will presently specify.

We are aware that immorality too often forms the staple of the correspondence between past schoolfellows, and, in this respect, is, alas, the sequel of the companionship that has preceded it. Lately, we have had cases brought to our notice in which "evil communications," in the shape of demoralising letters, have been addressed by persons—we cannot call them *gentlemen*—who have entered the army and other services, to their former schoolfellows, often very much their juniors.

This point of age is one of the most important; for we have found that men of twenty-four or twenty-five have been writing in the most abominable way to boys of fourteen or fifteen, and have even made appointments to meet them at immoral houses, and, of course, we may presume, they have introduced these mere lads to many forms of vice; in fact some of the correspondence seems to imply that the writers have sounded every depth of iniquity.

In presence of such immorality, we are not surprised at the action of those who have issued the advertisements we have quoted. Parents and relatives, especially mothers and sisters, must be inexpressibly shocked when such disclosures are first made, and ready to take any step to stop their loved ones being further corrupted. But, as we have said, this appeal is not likely to succeed, and we now beg to offer a suggestion which, if more severe would, perhaps, be more effective.

We would propose that parents, guardians, or heads of schools, into whose hands such filthy letters should fall, should publish the names, addresses, and occupations of the delinquents. Such an exposure would brand them with the infamy they deserve, and for ever shut the door of respectable Society in their faces. The fear of such a punishment would act as a most powerful deterrent, and we almost fancy that the publication of a determination so to act, would be so effective that we should hear no more of "officers and gentlemen" indulging in such "superfluity of naughtiness."

DEFECTS OF MEDICAL EDUCATION IN DUBLIN.

At the last meeting of the Medical Society of the College of Physicians of Ireland, Dr. Stokes read a remarkable communication "On some Requirements in Hospital Teaching in Dublin." Having reviewed the awakening of Medical Science in Ireland subsequently to the year 1820, he asked whether it could not be said that we are now drawing upon the prestige of former labours. He thought the Irish School had not kept pace with those modes of investigation which depended on physical science. He said it must be admitted that the English and Scotch Schools were in advance of Ireland in such a direction. In Ireland all educational facilities are dependent on charity, and teachers are dependent on private practice, while on the Continent such objects are amply subsidised by the State, and the teachers devoted solely to their didactic duties.

He considered that Ireland cannot yet compete in the domain of scientific medicine, although in the more superficial practical study it still maintains its position. It is

clear that the Irish School is deficient in the use of the best method of investigation. "The modern world," Dr. Stokes said, "is full of artillery, and yet we send forth our children to the battle with the shield and sword of the ancients."

He deplored the absence of systematic education of students in investigation in all Irish Schools, and compared the condition of Ireland, in this respect, with London, Oxford, Cambridge, and Edinboro'. He thought that to every hospital in Dublin should be attached a physical laboratory for the scientific investigation of diseases; and, in this respect, he considered their condition deplorable.

On the motion of the Reverend Dr. Haughton the debate on Dr. Stokes's paper was adjourned, and will occupy the attention of the Society at its next meeting.

SCOTLAND.

EDINBURGH.—Last Wednesday the managers of the Infirmary met to reconsider the subject of the admission of female students to clinical instruction. The seven female students, in a memorial of considerable length, claimed admission to the hospital—1. Because the University and the Colleges of Physicians and Surgeons have recognised their right to study medicine, with a view to graduation. 2. To this end two years' attendance at a general hospital is essential. 3. That the only hospital in Edinburgh supplying the necessary qualifications is the Infirmary. 4. That it is the invariable custom of the managers to grant admission to students, and no statute exists limiting admission to students of one sex only. 5. That as registered and matriculated students they are entitled to be admitted in terms of the manager's advertisement. Their pecuniary loss was also urged, if the tickets of their admission were refused, and an opinion expressed, that no objection could be raised to their attending clinical teaching even in the male wards, which does not apply with equal force to the instruction of male students in the female wards; and, finally, Miss Blake, in a separate note, asserted that no attempt would be made by any of the seven to enter the wards of those physicians and surgeons who object to their presence there. Against the first of the above reasons Dr. Gillespie, President of the Royal College of Surgeons, publicly protests as being calculated to convey the impression that sanction has been given by the Royal Colleges to female education in medicine, while it yet remains to be seen whether these corporations have, either the power or the inclination to legislate on the subject. In a short statement 504 students of medicine petitioned the managers of the Infirmary to refuse the application of the lady students in so far as it referred to the usual visiting hours, on the ground that if ladies were admitted at the usual hours many subjects would, probably, be imperfectly treated, or omitted altogether; or, in the event of such subjects being entered into, they should feel themselves compelled to abstain from being present. Had circumstances so distasteful to them been foreseen, they would have materially influenced them in their choice of a school of medicine. The managers have, by a majority of four, adhered to their resolution, and declined to issue tickets to any female student. It is stated that the female students, with singular pertinacity, intend taking legal advice on the subject.

The various medical societies have resumed their meetings. The Royal Medical, the most celebrated student society in Britain, was opened with an address by Dr. Haldam. This, its 133 session, promises to be prosperous from the number of applications for membership which have already been received.

We regret to say that the University students, those who have but begun their medical studies, are inclined to be somewhat lacking in courtesy to the females attending lectures in the College of Surgeons. We trust they will see the impropriety of this, and—let them alone!

ABERDEEN.—Additions are about to be made to the Lunatic Asylum, which will accommodate between sixty and seventy patients. The cost is estimated at £2,850.

According to the Registrar-General's monthly return the deaths of 1,942 persons were registered in the eight principal towns in Scotland during October. Allowing for increase of population, this number is 247 under the average of the month for the last ten years.

The managers of the Edinbugh Royal Infirmary have declined finally to grant tickets of admission to the female students.

Notes on Current Topics.

About the War and Wounded

IT appears likely that the English ambulance sent to Versailles will be of no service. The Germans assumed too much authority over the English Surgical staff. Half that staff have been sent to Orleans. We are not at all surprised at this matter, and would advise the Society to transfer its aid to the French, who seem to be in far greater need.

***

Frightful sufferings from disease around Paris, as we anticipated, is still the sad news. There is no doubt that the distress of the besiegers has been so great that the leaders are in dread. It is all very well to rely on the patience of the soldiery when the enemy is visible, but even veterans are afraid of the pestilence that walketh in noonday. We have been told of 2,000 burials a day. This is frighttul, and might account for the supposition of a willingness to treat.

***

The Belgian ambulance is a series of well-arranged huts, with a street between. Each hut is 40 feet long, by 25 wide, and contains 15 beds. A space of 30 feet is left between the huts. The ground under them is properly drained, and the floor is raised two feet above it. It costs about £9 to build each, exclusive of material. Common rough pine boards are used, and the roof is left open along the centre, some six inches, on each side the chief beam. Ventilation is further provided for by the upper part of the wiudows being made of wood, so as to open or shut, as required, and the planks of the floor are also half an inch apart. The mortality seems to have been unusually low in these huts.

***

A monthly contemporary lately made a virulent attack on our National Society, and it seems other papers have echoed some of its statements about partiality and mismanagement. It might well be that a little explanation would put a stop to these expressions of discontent. Did not the Society give its £20,000 to each side alike? Could there be partiality in that? Whatever our opinion as to the danger of subsidising Governments—if it is to be done, let it be done as it has been, in this equal mode.

Dr. Humphry Sandwith seems to think that there is not that urgent need for these Societies that has been supposed; and we confess that for sometime past our original doubts have been constantly growing upon us. We shall very soon hear on all sides what was said to us the other day—that we might as well have kept the money for our English sufferers. Money is flowing abroad, while hospitals at home have to retrench their expenses and curtail their efforts to alleviate sick sufferers. And then there is the great danger that seems to rise into such prominence, that our own soldiers may be called upon to do, dare, and suffer in Europe, and should we not be ready to help them first? In case, however, of this country being involved in war, we believe the whole exertions of the National Society would be directed to the care of our own troops.

***

Another question which seems as if it would come to the front is the condition of vast numbers of prisoners of war. Many of those in the rigorous climate of the North of Germany are insufficiently clothed, and inadequately fed. Yet, a considerable proportion of them came from the sunny South, and not a few have been habituated to Algeria. What must be their sufferings, and what may probably be the mortality among them this bitter season?

***

Then, there is still the possibility of Paris being starved, and all the agonies that involves. Verily, the cup of horrors prepared for Europe seems to be well-nigh full. And this is our boasted nineteenth century!—these horrors are brought about by the quarrels of the most civilized nations of the world.

The Dangers of Season-Ticket Holders.

Constant travellers on railways have often enough been warned of certain not well-defined dangers to which they are exposed, and many curious tales have lately been confided to us illustrative of these risks. We think, however, that some very easily avoidable perils should be pointed out, and foremost amongst these at this season of the year is that of cold. Several of our patients are now spending a season at Brighton, and we find that no effort is made by the Company to diminish the risk by warming the carriages. On the Continent, when the weather is in the least chilly, foot-warmers are always provided. A patient, who suffers much from cold, assures us that, even with the excellent express service between London and Brighton, none are provided, unless on special request, and that then they are charged for. We look upon this as meanness rather than economy. It is penny wise, but pound foolish. A delicate patient, or even a tolerably strong man, enters a cold railway carriage—perhaps after a walk to the station which has made him comfortably warm. For an hour and a quarter, or an hour and a half, he is sitting still in a cold atmosphere, which the necessity of ventilation constantly makes colder. The natural consequence is that, in spite of any number of rugs and wrappers, the circulation in the extremities becomes slower, the feet and hands get very cold, the blood is driven back upon the internal organs, and will inevitably find out any weak spot. Thus, the lungs may suffer considerably, and the heart, if at all weak, is likely to be seriously injured. When the circulation is in the least difficult, nothing is so important as to keep the extremities comfortably warm. So important is this that we are entitled to ask whether some of the deaths, attributed by writers on railway travelling to disease of the heart, might not have been hastened by the evil of which we are speaking?

In future, we intend to persuade any patient intending to take a season-ticket, to select a line of railway where the comfort of foot-warmers is provided by the company.

The Royal Institution Lectures.

The annual series of lectures delivered at the Royal Institution, London, are announced, and include the following:—

Christmas Lectures (adapted to a juvenile auditory): Professor Odling, F.R.S.—Six lectures on "Burning and Unburning," commencing on December 27th. Prof. Michael Foster, M.D., F.L.S.—Eleven lectures on "The Nutrition of Animals," on Tuesdays, January 17th, to March 28th. Prof. Odling, F.R.S.—Eleven lectures on "Davie's Discoveries in Chemistry," on Thursdays, Jan. 19th to March 30th. W. H. Channing, Esq.—Four lectures on "The Progress of Civilization," on Saturdays, January 21st to February 11th. The Friday evening discourses before Easter will probably be given by Professors Tyndall and Odling, the Dean of Westminster, Mr. E. J. Reed, Mr. James N. Douglass, Dr. Carpenter, Capt. Noble, Professor Clerk Maxwell, Mr. Norman Lockyer, Mr. W. Mattieu Williams, and Prof. Max Muller. *After Easter.*—Charles Brook, Esq., M.A., F.R.S.—Two lectures on "Force and Energy," on Tuesdays, May 9th and 16th. Prof. Tyndall, LL.D., F.R.S.—Eight lectures on Thursdays, April 20th to June 8th. Joseph Norman Lockyer Esq., F.R.S.—Eight lectures on "Astronomy," on Saturdays, April 22nd to June 10th.

Contagious Tall Talk.

At a public meeting at Rochdale, the Rev. H. Rothery moved: "That the Contagious Diseases Acts of 1866-9, which legalise *such outrages upon the persons of defenceless women as never disgraced the annals of negro slavery, with a view to securing safety in vice for profligate men*, are despotic, unjust, and immoral, and an insult to the whole manhood and womanhood of these realms." Has the Canterbury Hall no vacancy for *another* "stump orator."

The Relapsing Fever in Liverpool.

The Poor-law Board have received the following report from Mr. Cane, the Poor-law Inspector of the manufacturing districts:—

The number of cases admitted to this hospital first began to exceed those of the corresponding week of the previous year in the week ended the 28th of May last. From that period until very recently the numbers of cases of fever relieved in the hospitals have steadily and rapidly increased.

Date of Week, 1870.	No. of Cases.	Corresponding Week of 1869.
June 11	138	 95
July 16	233	 89
August 20	568	 79
September 24.....	1,116	 80
October 29	1,375	 94

It is thought that the epidemic of scarlatina in London is about to subside, as the deaths for the last four weeks have been 192, 167, 174, and 150 successively.

The Medical Club.

THE premises at present occupied by the Union Bank in Pall Mall East and Suffolk street, have been secured, for the purpose of converting them into a club-house, and the Medical Club will remove to them some time during the ensuing Summer. In the meanwhile it will continue to be conducted in the present house, No. 9 Spring gardens.

Cruveilhier's Atrophy.

THE Medical Society of the College of Physicians of Ireland held its first meeting on the 16th inst. The President, Dr. Banks, read a communication on "Cruveillhier's Atrophy." The first case he detailed was under his care since 1858, and he had published the facts in 1860. The subject was thirty-four years of age, came of a very healthy family. Having caught cold, he commenced to suffer from persistent pain in his right arm, which after some time resulted in weakness in his right thumb, extending afterwards to the right, and subsequently to the left. Examination of the muscles showed there was considerable atrophy of the muscles of the arm and hands. The treatment in hospital consisted in the application of electro-magnetism, and the internal administration of syrup of phosphate of iron, quinine, and strychnia, which was attended with considerable benefit, which remained established for some years, and until he suffered from a severe sickness, since when he has steadily got worse, his lower extremities became paralysed, and he is now in a moribund condition. The second case was that of a lady, whose father had been the subject of locomotor ataxy, and had died of apoplexy. The treatment was similar to that adopted in the previous case, but without the least effect, the disease commencing in the thumb, and in fifteen month involving the lower extremities. In the last stage of the malady there was a very marked difference in development between the face and other parts of the body. Hyperæsthesia is one of the prominent symptoms. In the third case complete recovery resulted, although the symptoms had reached so advanced a condition, that the patient was able neither to write, feed himself, or walk. Dr. Banks quoted three other cases, in one of which the symptoms has made no advance for six years, while in the others the progress was rapid, the disease commencing in the left leg in one, and in the left arm in the other. He remarked that up to a recent date this disease was considered absolutely incurable.

Sir Dominic Corrigan considered that it was not necessary to assume any lesion of the spinal cord as the cause of the local paralysis. He narrated the case of a gunner on board ship, who at the age of thirty-three became disabled, suffered from complete atrophy of the deltoid. In this case he had failed to discover the least central disease. Sir Dominic Corrigan had treated the case by stimulation of the capillary nervous system with perfect success.

The late Dr. J. Gedge.

WE have to announce the death of Mr, Joseph Gedge, M.B., of Caius College, Cambridge, son of Mr, Johnson Gedge, Bury St. Edmunds, Physician's Registrar at Addenbrooke's Hospital, and Demonstrator of Histology in the University medical schools, who went as medical officer with the expedition under the command of Sir Samuel Baker. The expedition had got over the passage of the Desert of Dongola, and had reached the station between Khartonn and Gondokoed. A telegram from the correspondent of the *Times* at Alexandria announced Dr. Gedge's death, and it has since been confirmed by intelligence received through the Khedive's Minister of the Interior.

The late William A. Hubert, M.R.C.S.

THIS gentlemen was lately found dead in his bed, at his residence, Markyate street, Dunstable, Beds. He was fifty years of age, and on the day prior to his death, seemed to be in good health, going about his business as usual.

Health of the Princess Louise.

WE have much pleasure in recording that Professor Lister, Surgeon in Ordinary to the Queen, on Friday last, went from Edinburgh to see Her Royal Highness Princess Louise, whom he found progressing very favourably, and there is every reason to believe that Her Majesty will be able to leave Balmoral in the course of the ensuing week.

This intimation will be read with greater satisfaction, as coming from official sources. We make no pretence of special favour, although our source of information is quite as "special and particular" as that which whispers the state of the "Sick Lion" in the ear of the *British Medical Journal*.

Alleged Yellow Fever in New York.

SEVERAL cases of death have occurred within the last week in New York City attributed to yellow fever. Dr. Moreau Morris, however, who is City Sanitary Inspector, denies that such is the character of the disease. He says, that *post-mortem* examinations upon their bodies gave satisfactory evidence that the disease was not "yellow fever." In order to ascertain all the facts connected with these cases, and, if possible, the source of the disease. minute inquiries were made. The general symptoms of the disease presented by those attacked were chill, fever, diarrhœa, vomiting, slight jaundice, brown coated tongue, urine of a dark colour, which, under the microscope, presented no casts, blood or albumen. The average duration of the disease in fatal cases was less than a week.

Lead Poisoning.

THE *Food Journal* has received very important communications on this subject from two contributors; Professor F. Crace Calvert, says :—"Great numbers of private houses have a leaden cistern heated by means of a continuous current of hot water, fed by a boiler placed behind the kitchen range on the ground floor. The cooled water from the cistern returning to the boiler is of course charged with all the lead dissolved from it; and as the occupiers of these houses are either not aware of the action of water on lead, or do not reflect that the water which they take from the kitchen range for domestic purposes has circulated through the cistern above, it is not surprising that many of them fall victims to lead poisoning." Professor Church, of the Royal Agricultural College at Cirencester, points to a similar danger, resulting from the use of gazogenes for preparing aërated waters. He says :—"I have examined a large number of different waters—English and foreign, old and new—and I find one defect universal. The upper part of the long glass tube (through which

the aërated liquor is forced from the lower vessel) is fitted into a tube of pewter. The aërated water standing in this dissolves some of its lead; and the first wine glassful of water drawn each time that the apparatus has been left to itself, turns brown when tested with hydro-sulphuric acid."

Failure in the Preserving of Australian Meat.

THE *United Service Gazette* notices that twenty-seventy thousand pounds of Australian preserved meat sent per P. & O. Company's vessels to Bombay for the use of the Indian troopships have lately been condemned at that port as wholly unfit for food, and it has been found that the meat prepared at the Royal Victoria Victualling Yard, Deptford, which was ordered to be opened by the surveying officers for purposes of comparison, was of very fine quality and in beautiful condition.

The Subject for the Hastings Medal.

THE subject selected for the Hastings Gold Medal, value twenty guineas, for 1872 is "On Investigations on the Germ Theory of Disease;" and the award will be at the Annual Meeting of the Association in that year.

Royal College of Physicians of London.

THE Primary Examination for the Licence of the Royal College of Physicians of London, will commence on Monday, December 5th, and the Pass Examination on Monday, December 12th.

Jervis-street Hospital, Dublin.

THE medical staff of this hospital inaugurated the session by a dinner at the Gresham Hotel on Thursday evening. The President of the Royal College of Surgeons, with Dr. Adams, and several of those gentlemen who, at one period of their career belonged to the hospital, were the guests. Dr. Stapleton, senior surgeon, occupied the chair, and Dr. M'Swiney the vice-chair. The usual loyal toasts having been duly proposed and honoured, the Chairman gave the toast of the evening, "Jervis-street Hospital, its Fame, and Memories." He alluded in eloquent terms to its usefulness as a charitable and educational institution and enumerated the many names connected with the hospital which have become illustrious. Sir Dominic Corrigan, and Dr. Robert Adams, the first Physician and first Surgeon of Ireland in the present time, with Kirby, Wallace, Neligan and O'Reilly of the past. In speaking of the harmony and good feeling which enabled the staff to cooperate for the good of the sick poor, he paid a deserved tribute to the excellent ladies, who so admirably assist the medical officers in their humane exertions.

Army Medical Department.

STAFF Assist-Surg. Bate has been granted leave of absence from Bantry until required to embark for India; Staff Assist-Surg. Stevenson has left Dunmore for Bantry, for duty; Staff Assist-Surg. Notter has been ordered to the Pigeon House Fort, Dublin, for duty; Staff Assist-Surg. Churchill has joined at Dublin for duty; Staff Assist-Surg. Smith has been ordered from Dublin to Tralee Staff Assist-Surg. Burnett has been transferred to Bandon from Navan, to replace Staff Assist-Surg. Ryan, ordered to Dublin.

The Society of Arts.

THE following communications are announced to be read at the Society of Arts, during the coming month:—

November 23.—"On South African Diamonds." By James Tennant, Esq., Professor of Mineralogy, King's College, London.

November 30.—"On Peat, and its Profitable Utilisation." By Robert M. Alloway, Esq., M.A.

December 7th.—"On the American System of Associated Dairies, and its Bearing on Co-operative Farming." By H. M. Jenkins, Esq., Secretary of the Royal Agricultural Society of England.

December 14.—"On the Study of Economic Botany." By James Collins, Esq., Curator of the Pharmaceutical Society, and Fellow of the Edinburgh Botanical Society.

December 21.—"On a Method of Lighting Towns, Factories, or Private Houses, by means of Vegetable or Mineral Oils." By Albert Sibler, Esq,

Fraternisation with Homœopaths in America.

AN American paper informs us of a strange proceeding which took place at the Albany Medical School, and which it considers is a subject for the gratulation of its readers:—

"The Hon. Ira Harris delivered the opening address at the College yesterday morning. The address was able and interesting, and we were pleased to see many homœopathic physicians in attendance. Mr. Harris is a firm believer in and patron of homœopathy, and fills a chair in the College. It is indeed gratifying to know that the barriers which have hitherto divided the two schools of medicine are being removed, and to see our College taking the initiatory step towards such a desirable achievement. We believe this is the only allopathic medical institution in this country that possesses views sufficiently liberal to allow any of the chairs to be filled by men who firmly and practically believe in the homœopathic doctrine. It is also pleasant to know that several of the trustees of the College are firm believers in homœopathy."

It seems to us an abuse of the quality of liberality to apply the term to fraternisation between scientific physicians—if the medical staff of the Albany School deserve that name—and homœopaths. It would be characterised as indecency, and not as liberality, if a judge were to hobnob with a convict, or a bishop with Mr. Bradlaugh, and, if medical men have any real belief in the theorems of their profession, there cannot be in their minds much greater consistency between themselves and homœopaths. Homœopathy is not a theory of medicine with which medical men can agree to differ. We may respect hydropaths, or eclectics, however mistaken and foolish we know them to be, because it is possible to believe that they hav real confidence in their systems, but it is too hard for us to suppose that homœopaths believe in their billionths, and their snuffs of starch. They drive us to the conclusion that homœopathy is a false pretence, and, therefore, that their practice of such means to obtain money disentitles them to be our associates. Possibly the Albany Medical School may afford a genial companionship to such persons—"Birds of a feather," &c.

"HOSPITAL SUNDAY" in Birmingham produced this year the sum of £3,947 10s. 7¾d.

The Prevalence of Scarlet Fever in England.

In the 17 large towns of England making weekly returns to the Registrar-General the deaths from scarlet fever in the week ending on Saturday, the 5th of November, were as many as 330. In London they were 174, besides 45 deaths from other fevers; in Liverpool they were 38, besides 37 deaths from other fevers; in Bristol the deaths from scarlet fever were 31; in Leicester, 22; in Birmingham, 15; in Norwich, 10; in Sheffield and in Hull, 8; in Manchester, 6; and in Salford, 2; in Leeds, 5, besides 11 deaths from other fevers; in Newcastle-upon-Tyne, 3; in Nottingham, in Bradford, and in Sunderland, 2; in Portsmouth and in Wolverhampton, 1. Not one of the 17 towns was without a death from scarlet fever in the week. The number of such deaths in Liverpool shows a decrease of 12 compared with the previous week, Bristol an increase of 5, Leicester of 6, Birmingham of 10. The deaths from scarlet fever in the 17 towns were 332 in the week ending the 8th of October, 325 in the next week, 352 in the next, 319 in the next, and, as already stated, 330 in the week ending the 5th of November. The aggregate population of the 17 towns is about 6¼ millions.

Royal College of Surgeons of England.

The Council of this institution have elected as a Fellow Murdoch Kelburne King, M.D. and F.R.C.S. Edinb., Hull. This gentleman was elected an *ad eundem* Fellow, which, it is stated, is the first occasion in which this honour has been so bestowed since the charter for conferring the Fellowship was granted to the College of Surgeons.

Prevention of Baby Farming.

A number of well-meaning and zealous people seem anxious to import a deal of the bureaucratic customs of the Continental nations into this country. A few days ago some of such gentlemen had an interview with that wonderful Home Secretary, Mr. Bruce, who recently compared the French nation to burglars, and has done so many other statesmanlike strokes during his brief period of authority. The deputation asked from Government that every woman who suckled a baby not her own, should be obliged to go and notify that fact at some office. This idea resembles the Habitual Criminals Act a good deal, and the famous Contagious Diseases Acts. Why not go further and get every unmarried man and woman to register themselves, in case they should bring into the world an illegitimate child. This would please the Puritans enormously, and those persons who wish to reduce human society to the Chinese type. But what about individual liberty, if Government spies are to be so prevalent in future?

Absorption of Mercury through Skin and Mucous Membranes.

Dr. Rindfleisch, of Bonn, has been making some experiments on rabbits with mercurial ointment, which are worth relating. In order to prevent the animals licking the parts, the ointment was rubbed into the inner aspect of the ears. After rubbing the ear of a rabbit for some time with blue ointment, and washing the part with soap and water, the ear was snipped off, and laid under the microscope. After making these preparations, Dr. Rindfleisch became convinced that not one particle of quicksilver passed through the epidermis. The malphigian net was quite free from any particle. He then put some blue ointment into a rabbit's eye, closing up the eyelids by sutures. The result again was negative; no particle of mercury passed through the conjunctiva. Convinced that the result would be different in the bowels, he fed rabbits with potatoes in which blue ointment was mixed. They died pretty quickly. The mucous membranes of the bowels were found hyperæmic, and some small ulcers covered the membrane in many parts. There were quicksilver particles found in the intestinal glands, absorbed by the open mouths of the absorbents from the ulcers. The blood did not contain a single particle; nor did the liver, spleen, lungs, brain, kidneys, or bones. Next, small pieces of blue ointment were placed in the peritoneal cavity of rabbits; and the result was again negative. There were particles found in the lymphatic of the diaphragm; but only there. Dr. Rindfleisch, therefore, concludes—1. That quicksilver contained in mercurial ointment passes neither through the outer skin, nor the mucous membrane, nor the serous membrane, so long as these are inviolate; 2. That it, on the other hand, passes along the open parenchymata of the body, through open lymphatic vessels and the base of phagedænic ulcers.

The Royal Society of Medicine.

So little cohesion exists in our *fraternity* in London, that the proposed Amalgamation of the Societies has fallen to the ground. The cause for this effect is alleged to have been the hostile attitude of the Obstetrical Society. If this be the case, we may look forward to the day when the Obstetrical Society shall be old enough and dignified enough not to fear that it will be slighted if it unites its fate with the other branches of the medical art. But, why is there not an Andrological Society also?

Climate of Algeria.

Dr. Henry Bennett says, that Algeria comprehends a country of 400 miles long from east to west, and some 120 miles from north to south, where Sahara commences. None of the mountains are more than 7,000 feet high. There seems to be only thirty days of wind blowing from the desert annually; during the rest of the days of the year, a moist sea-breeze blows. Six-sevenths of the rain falls in the winter season, and as much as forty cubic inches fall in the year. Thus, Algeria is a very moist climate in winter. The valleys and mountains have a very luxuriant vegetation. The climate is rigorous in winter in many parts, but Algiers town seems of mild climate. Algeria is, thus, on the whole, a mild and moist climate, not suitable for patients with tendency to phthisis pulmonalis; the east coast of Spain is dry and warm; only fourteen inches of rain-fall in that district, and it is better suited for such invalids. Idiopathic asthma and neuralgic cases, he thinks, might be benefited by living in Algeria.

Psychological Journals.

In our younger days psychology was defined as the science of the laws of the mind. Now-a-days, psychological journals are written chiefly by physicians of lunatic asylums, and a good deal of sociology is debated in their columns. In Dr. Hammond's *Psychological Journal* for October, there are pictures of the degeneration of the human race given, which might appal all who were not,

like ourselves, practical medical men. In England the race is said to be deteriorating, owing to late marriage, excessive breeding of children, and want of facility of divorce, to which is added tobacco smoking. In France the race is said to be degenerating from paucity of births, luxury, and all sorts of vice. In America, too, it is degenerating from artificial limitation of babies and smoking. Doubtless, the main fact will be found to be that poverty and ill-assorted unions are the chief causes of bad breeds. Tobacco smoking and alcohol drinking, of course, must be added as causes; we presume that the writers in Dr. Hammond's journal consider that marriage without divorce is injurious, because it keeps together people who ought not to reproduce themselves together, such as persons of consumptive or insane families. Certainly, a great deal might be done by careful selection of breeders to improve the race.

New Books in Medicine, Surgery, and Science.

The following books referring to Medicine, Surgery, and the Collateral Sciences, will appear within the forthcoming Session:—

A Handbook of Stomach and Liver Diseases: With Especial Reference to Tropical Climates. By James C. Dickinson.

Diseases of the Heart and Great Vessels; Their Pathology, Diagnosis, Symptoms, and Treatment. By H. W. Fuller, M.D. Cantab, F.R.C.P.

A Practical Treatise on the Diseases of Women. By Robert Barnes, M.D., F.R.C.P. 8vo.

Contributions to the Science and Practice of Surgery. By T. Spencer Wells, F.R.C.S.

Ovariotomy. Illustrated by 12 Plates and numerous woodcuts.

The Practice of Surgery. A Manual. With Numerous Engravings on wood. By Thomas Bryant, F.R.C.S.

The Science and Practice of Surgery. By Frederick J. Gant, F.R.C.S. 8vo.

On Rheumatic and Strumous Diseases of the Joints; Including Hip-Joint Disease, and the Treatment for the Restoration of Motion in cases of Stiff-joint or Partial Anchylosis. The Lettsomian Lectures for 1869. By William Adams, F.R.C.S. 8vo.

On Deformities. A System of Orthopædic Surgery. By Bernard E. Brodhurst, F.R.C.S.

A Laboratory Text Book of Practical Chemistry; or, Introduction to Qualitative Analysis. By Wm. G. Valentine, F.C.S.

A System of Surgery. Edited by T. Holmes, M.A., St. George's Hospital. Second Edition, in Five Volumes. [The Fourth and Fifth Volumes, completing the New Edition of this work, will appear successively in the course of the present autumn.]

Select Methods in Chemical Analysis and Laboratory Manipulation. By William Crookes, F.R.S., &c.

Principles and Practice of Physic. By Sir Thomas Watson, Bart., M.D., D.C.L., F.R.S., &c. New Edition.

Dr. Scoresby Jackson's Note Book of Materia Medica, Pharmacology, and Therapeutics. Second Edition. Edited by Dr. Angus Macdonald.

Thoughts on Health and Some of its Conditions.

Dr. Roberts on Urinary and Renal Diseases. Second Edition.

Hand Book of the Principles and Practice of Medicine. By James Andrew, M.D., Physician to St. Bartholomew's Hospital.

Dr. Garrod's Materia Medica and Therapeutics. Fourth Impression of the Third Edition.

A Manual of Zoology, for the Use of Students. By H. Alleyne Nicholson.

A History of Animal Plagues. By S. Fleming, R.E.

The Intelligence and Perfectibility of Animals. Taken from the French of Charles George Leroy.

Thesaurus Entomologicus: or, A Description, with Plates, of the Rarest Insects in the Collection given to the University by the Rev. William Hope. By J. O. Westwood, M.A., Hope Professor of Zoology.

Macmillan's Manuals for Students. An Introduction to the Osteology of the Mammalia. Lectures delivered at the Royal College of Surgeons. By W. H. Flower, F.R.S., F.R.C.S.

Proceedings of the Birmingham Natural History and Microscopical Society during the year 1869.

The Mollusca of the European Seas. By Mr. Gwyn Jeffreys, F.R.S., in continuation of his Work on "British Conchology."

The Natural History of the British Diatomaceæ. By Arthur Scott Donkin, M.D.

A Fourth Edition of Professor Rymer Jones's Organisation of the Animal Kingdom. The Natural History of the Azores. By F. Du Cane-Godman, F.L.S.

(To be continued.)

At the taking of the last census in the United States there were 55,000 physicians, 11,000 druggists; at present there are 74,000 physicians.

Mr. Lawson Tait, surgeon, of Birmingham, has been entrusted with the task of editing the posthumous works of the late Sir James Simpson, of Edinburgh.

According to Dr. Boyd Mushet, cod-liver oil was first used by Dr. Perceval, of Manchester, in chronic rheumatism at the end of last century.

The usual February Examination for the Indian Medical Service will not take place next year in consequence of information received from the Government of India.

Small-pox still increases in London. A chapel at Hoxton has been purchased by the Shoreditch Board of Guardians, to fit up as a temporary hospital for small-pox.

The Council of the Apothecaries' Hall of Ireland has selected "The British Pharmacopœia" as a subject for the annual prize of five guineas, to be competed for by apprentices, upon the first Monday and Tuesday in May, 1871.

Mr. Christopher Heath and his colleagues in the Hospital for Women, Soho square, are about to deliver evening lectures in the Hospital during the months of January, February, and March. The great abilities of Mr. Heath are sure to gain him a numerous auditory.

A PARAGRAPH appeared in our last issue relative to Dr. William Mac Cormac, of Belfast. The statement which found its way into our columns was, at least, unauthorised by him, and premature; and we much regret that it proved a source of annoyance to one who is valued both as a friend and as a contributor to this journal.

LORD HENRY LENNOX, in his address to the Society of Arts, notices that Parliament has at length voted a sum of money for the construction of a suitable building for the accommodation of the collections of natural history possessed by the Society. This museum will be placed on part of the ground which formed the site of the International Exhibition of 1862.

A NOVEL (and in our opinion peculiarly objectionable) mode of electing a hospital officer took place at the Queen's Hospital, Birmingham, on the 7th inst. One hundred governors selected by ballot from the whole number formed a committee for the election of an obstetric surgeon to the institution. Thus, the old system of canvassing was done away with. Mr. John Clay was elected by a majority of 25.

DR. ALRIK LJUNGGREN, of Stockholm, has shown in some clinical observations on visceral syphilis, translated into German by Dr. Diemer, for the *Archiv für Dermatologie und Syphilis*, 1870, that syphilis causes insanity and many forms of fatal nervous disease. His cases merit perusal by all who read German. Every day we become convinced how much it would add to the happiness of this race if such preventible diseases, as syphilis, could only be prevented. We suspect that some fundamental changes in marriage are required to bring about this effect.

Correspondence.

CHLOROFORM IN THE REDUCTION OF DISLOCATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Will you kindly have inserted the following case of hip-joint dislocation if, on reading you deem it of any value for your practical journal.

I was asked by my colleague, Dr. George Walker, of Bonanahon, to see with him on the 8th inst., a poor man, aged about sixty-eight years, who had sustained a dislocation of hip-joint into the foramen ovale, the diagnostic symptoms of which were well marked by the usual separation of the injured thigh from the other, with a slight lengthening, and the patient keeping his body flexed forwards to relieve the tension of the psoas, iliacus, and other capsular muscles; the man was strong and apparently healthy for his age, but had weak sounds of heart without any valvular disease. Dr. Walker and I first endeavoured to reduce the dislocation by manipulation without chloroform, but had to desist, owing to the struggles of the patient, and great muscular resistance. We then resolved to use chloroform, and before its use, gave a glass of whiskey in water to the man, as a necessary precaution against any danger that might arise from the chloroform, owing to its action over a weak heart. Dr. Walker most efficiently administered the chloroform, and in about ten minutes, the patient was fully under its influence, the quantity used, being two drachms. I then flexed the leg on thigh, and the latter on the abdomen, at the same time lifting up the extremity, and very forcibly rotating inwards; the head of the bone slipped into its place *in situ* with a loud noise, the patien t being perfectly passive and insensible to any pain during the manipulation of less than ten minutes, before reduction was effected. I deem this case of interest to practitioners in dispensary or country practice, where many such cases may occur in localities not having hospital or other resources; but, nevertheless, with the all-powerful aid of chloroform, together with the simple and ready mode of manipulations, a surgeon may be filled with confidence as being enabled to meet the difficulties of many dislocations successfully and promptly, in the poor man's cabin, as well as in the surgical wards of an hospital. In this reported case, Dr. Walker and I effected the reduction of the dislocation, the patient being in his own cabin, as we could not, prevail on him to be removed from home into the union workhouse hospital under my care.

I remain, dear Sir, yours faithfully,

Kilmacthomas, Nov. 11, 1870. HUGH GREEN, M.D.

ACONITE: ITS USE IN AFFECTIONS OF THE RESPIRATORY TRACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—How astounded must the Father of Homœopathy have felt could he only have heard Cabarus exclaim "I give aconite by the teaspoonful, while the allopaths give it in drop doses." Surely, the above-mentioned disciple of Hahnemann had but little faith in infinitesimal doses, or the solution of aconite he used must have been wofully weak; the latter, perhaps, is nearer the mark, though extraordinary luck does sometimes attend the heroic administration of certain remedies in solitary cases. Aconite has generally been known to exercise a decidedly beneficial therapeutic action in the congested mucous membrane of the nose, pharynx, larynx, and bronchi. If Dr. Luther will read Dr. Prosser James's work on "Sore Throat and the Laryngoscope," he will there find that aconite has been used by that author both frequently and largely, but in rational doses, with great benefit and success in affections of the throat. Following his practice, I have known it do much good in febrile and catarrhal affections myself.

Apropos of its being advertised as a specific for broken-winded horses, I was told some time ago that aconite given in drop doses every hour for sixteen out of the twenty-four until its physiological action became apparent, was a certain cure (if I may be allowed the homely expression) for gonorrhœa.

I am, Sir, yours, &c.,

HENRY W. WILLIAMS, M.D.

168 Fulham road, S.W., Nov. 18, 1870.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I had intended making some comments on Dr. Curran's note in your issue of November 2nd, but I am happy to see two rational and practical letters on the subject in the PRESS of last Wednesday.

The question is an important one in a social point of view, specially when we consider the disgusting and childish freaks of the supporters of the Anti-Contagious Diseases Acts movement. If it is to be considered practically and truthfully, we must put aside gallantry or allusion to any theory that is not founded on facts impartially collected.

In the quotation from Dr. Tait's work (which I had never heard of before), Dr. Smith mentions that about 18 per cent. would represent "the consequences of seduction." In this view I entirely agree; but I think that the percentage is too high. Melancholy and overwhelming to our notions as this may appear, there is no doubt but that the stern reality of facts will prove it. The instances are, I think, rare where seduction, in the ordinary sense of the word, has been the true means of turning from virtue's path; and as to the results of the arts of "Seducer, Esq., boasting over his exploits;" so ranted about in Dr. Curran's communication, they are inappreciable here, at all events, whatever they may be in the favoured spots of Dr. Curran's acquaintance, where "no country village or town is without him."

Why is it that where girls are most congregated together, in factories and such like, that they fall, and fall early? "Seducer, Esq.," with all his supposed insidious arts,—"unmarried, well-looking, ever on the *qui vive* to betray and to destroy"—would with greater success turn his attention to

some solitary innocent, whose guilelessness would offer him every facility for the exercise of his cruel and insinuating art. It is evident that the systematic seducer has nothing to say to their frequent fall, just as in the case of widows and married women, who err with a full knowledge of the results.

There is no escaping the conviction that a certain want exists in some female minds which, either with or without the stimulus of evil communications by fallen and, perhaps, undiscovered associates, leads them to destruction; and notwithstanding every care on the part of parents, the downward tendency will develop itself, and that persistently. It is very remarkable that the tendency is a persistent one, thorough and heartfelt reformation being almost problematical. There are some rare exceptions I will admit. I do not allude to such cases as when, having smarted from the consequences of her evil life either by disease, accident, or hardship, one will enter a reformatory, which affords a more or less permanent asylum. I call reformation where such a change takes place as that the once erring can be trusted to herself, and who has determined to abstain from a life of degradation, be it secret or open. Were we prepared to go into the discussion in all its bearings, I could multiply instances not only by the dozen, but by the hundred, to show that the subtle and insidious advance of the "Seducer, Esq.," in the stage shape represented by your theoretical correspondent was not an element of destruction. Let us take a few stubborn facts. Some time since, in order to substantiate the evidences forced upon me, that the much-talked-of and elaborate process of seduction was, to a great extent, a myth, I inquired of the nurses attached to an institution which admits something like 800 annually of these so-called victims of seduction. One nurse, twenty-seven years attached to the institution, stated, "I am ashamed to say it of my sex, but it is women and not men that do the mischief and lead each other to destruction, and as to reformation, during my long experience, and on considering the many thousands I have seen, I think I might say I only know of about six cases of real reformation,—that is, women who subsequently lived correctly, and earned their subsistence honestly."

"I have known women who have been fifteen years in reformatories, and yet at the end give way, and become worse, if possible, than ever."

Another nurse, of nearly twenty years' experience, stated, "The great evils are company keeping, bad female influence, and drink; as to reformation, I would be almost afraid to say I know of any cases really reformed, but perhaps half-a-dozen. I know of women who still come to this institution whom I remember when I first came here, as young girls, almost children."

The porter, of ten years' experience, stated, "He does not know of any really authentic and permanent cases of reformation of women who once came to the institution that have not come from time to time during these ten years."

I place infinitely more reliance on statements derived from these sources, because the real state of facts would be known to them, than on the sanguine reports of clergy or of good-natured patrons of reformatory and other institutions. I by no means undervalue these asylums as of a certain use; but that they are not as successful as might be supposed arises from the same moral defect, or want of regulating power, which impelled the first essay in vice, and which continues to exist *en permanence*.

The great cause of the fall of young girls, I still assert, is female influence. Not long since a young girl of sixteen stated that she was a servant in a respectable family, and made acquaintance with the neighbouring servant girl, who was depraved; the latter persuaded the younger girl to stay out one evening, and brought her to a preconcerted arranged place of meeting, where, when the victim begged to be let away, her female seducer absolutely put herself against the door to prevent her escape; she never went home afterwards, but entered on an evil life.

Another girl, of seventeen, stated that she casually made acquaintance with a girl already fallen, but not known to her; she enticed her to a place of meeting, plied her with drink, and the victim remembered nothing further till awaking in the morning; her female seducer dividing the price of her ruin.

Such instances could be endlessly multiplied. Female influence—sometimes for the sake of gain, sometimes for the sake of companionship, sometimes from recklessness—is the really most efficient cause of fall; the barrier is gradually and insidiously broken down by an unsuspected source. The moral want exists which renders resistance but feeble; or, it may be so far deficient as to make the tendency irresistible, and one bad woman is more dangerous to her sex than 100, aye, 500, men.

The intoxicating influence of the love of dress is almost irresistible. All, except the very lowest, are equally subject to its spell; if the virtuous, the educated, and the intellectual are so influenced by it—as we know they are—surely it may reasonably be allowed a place as a most destructive element with the weaker and the more imperfectly trained.

There are bad women, just as there are bad boys and bad men; at the school and at the college; in business and at professions, are there not bad men? To put it in plain language, are there not occasional, though exceptional, liars, dishonest persons, slanderers, &c.? Is not the boy that is a peculator at school generally so, in a modified degree, when a man? Is not the boy, remarkable at school for untruthfulness, the same often in manhood? The absurd rhapsodies of theorists such as your correspondent are calculated to do much harm in reference to a subject, ethically and morally, so difficult.

Dr. Curran, in remarking on my letter, asks me what will I say to a heartrending account quoted by him from the *Times*? I answer, it looks very well on paper, but neither he nor I have had an opportunity of ascertaining the real truth of the facts stated. It seems introduced as an excuse that the girl "was seduced under promise of marriage." Not the slightest excuse, say I; should the thief found stealing your purse be the least excused if he had been told that, if found out, he would be let off? She parted with her modesty voluntarily, and under promise, if you please. *Why should she?* Once so, she starts on the wild tempestuous ocean of vice, and must risk the dangers. As to Earls, Chancery barristers, &c., I take it, they are no better or worse than other men, in proportion to their position and affluence, they are capital scapegoats for man and woman kind in general.

I fear, indeed, Dr. Curran, in writing about what he knows little or nothing about, has ventured—

> "Like little wanton boys that swim on bladders,"
> "Far beyond his depth."

As to statistics, if Dr. Curran will kindly give his, as to the "heroes"—"that we all know," he says, "who glory in their exploits," and who "are ever on the *qui vive* to betray and destroy,"—and as to their victims also, I will be happy to give mine based on facts, startling no doubt, but not so contrary to our accepted ideas as some of Dr. Curran's remarkable experiences, of which I have seen one very instructive instance recorded—MEDICAL PRESS, April 7, 1869, page 286—where the Doctor, when called to a case of puerperal convulsions, finding "*a rigid and unyielding* os uteri," at once applied the forceps, and delivered the woman.

Alas, poor Irish obstetricians, here is a lesson for you from the sister kingdom—you will be instructed.

Alas! fathers, mothers, clergy, practitioners, one and all, the man-eater lurks about your villages; the "Seducer, Esq.," "the unmarried well-looking Esquire is on the *qui vive* to betray and destroy," the writer from England says, "we all know him"—*fenum in cornu*—take care of him. I am satisfied, nevertheless, that the *truly modest* may still fearlessly repeat—

> Sir Knight, I feel not the least alarm,
> No son of Erin will offer me harm;
> For, though they love woman and golden store,
> Sir Knight, they love honour and virtue more.

Yours,

VERITAS.

University College Students' Christian Association.—The annual meeting of this Association was held on Thursday evening, Nov. 3rd. About forty students were present. The chair was taken by Dr. F. T. Roberts, assistant-physician to the hospital, who gave an interesting and earnest address to the students. The president, Mr. H. J. Benham, who we may say, has just taken the first place in honours in anatomy, both at the College and the University, then briefly explained the objects of the Association, after which the Rev. Dr. Stebbing, Dr. Gowers, and Messrs. Smith, Read, Barlow, and Maxwell addressed the meeting.

EARTH CURRENTS.

Mr. W. H. Preece contributes an interesting article to *Nature* on the connection that exists between the Aurora Borealis and that great apparent rush of electricity through the crust of the earth which eagerly seizes upon the easy paths offered to the passage by the wires of the telegraph, and by filling them with electricity, produces what are called "earth currents," or "deflections." The aurora is always accompanied by such displays, but it is rarely in England that they are of such strength as to absolutely break down telegraphic communication. The earth currents of October 24th and 25th have only been equalled by those which occurred in 1859. The following extracts from the diary of one of the largest telegraph stations in the South of England will be found interesting:—

Oct.	24, 5.0 p.m.	Slight deflections on all long circuits.
„	5.30	Gradually increasing.
„	6.0	Very strong; circuits suspended for ten minutes.
„	7.0	Gradually increasing.
„	8.15	All circuits right.
Oct.	25, 3.0	Deflections, which have been intermittent all day, or very strong.
„	3.30	Circuits nearly all stopped.
„	4.0	Working through on some circuits, but slow.
„	5.0	Deflections increasing.
„	5.45	On again; all circuits suspended.
„	6.15	Deflections decreasing again.
„	7.0	Circuits clear.

This is only a sample of what occurred simultaneously all over England, and probably the globe. The currents were very irregular in their direction and very variable in their strength. Circuits running S.W. to N.E. are usually most powerfully affected, but on this occasion all directions seemed equally affected. Where two or more wires run between two stations, the effect of these currents upon the working is easily remedied by substituting the second wire for the earth to complete the circuit. This practice was largely adopted on Monday and Tuesday last. The most striking fact observed was that on each occasion the currents *ceased* when the auroral display *commenced*. I have not noticed this before, probably because the cessation of the one phenomenon and the first appearance of the other have scarcely ever before been so strongly indicated.

ST. PANCRAS BOARD OF GUARDIANS.

A public inquiry instituted by the St. Pancras board of guardians was held at the vestry hall recently for the purpose of investigating charges which had been preferred by Mr. James Watkins, a member of the board of guardians, against Dr. Hill, medical officer of the workhouse, of vaccinating children in bad health, and charging fees for them as successful examinations. A report was read which Dr. Hill had made to the Poor-law Board in reply to the allegations that numerous complaints had been made of the indiscriminate manner in which children had been vaccinated. No such complaints, Dr. Hill said, had been made to him; he had always used the greatest care in examining the children before vaccination; and, when re-vaccination was found necessary, care was always taken that the children were in a proper state of health. A man named M'Donald who had stated that his six children had been vaccinated without his consent, although four of them had been previously vaccinated, refused to attend and give evidence, stating that he should only be satisfied with a Poor-law inquiry. A statement of the facts having been made by Dr. Hill, a resolution was pased to the effect that the board were satisfied that Dr. Hill has performed his duty, and acquitted him of all blame in the case of M'Donald. Other cases were subsequently investigated with similar results.

A MONSTER INFANT.

Professor Little and Williams, of the Ohio Wesleyan University, gives the following authentic account of a monster now living in the United States, and subjected to careful examination by them.

"Two perfectly formed heads, one on either end of the spinal column. To give a clear idea of it, just suppose that you sever the bodies of two men at the lower part of the abdomen and then put the upper parts together, and you have the trunk of this child. From the occiput of one child to the occiput of the other, there is a continuous spine, in a direct line. Upon one side, and directly in the centre of the trunk, were perfectly developed hips, thighs, legs and feet. They are in nice proportion to the body of either child. On the opposite side there is one large, imperfectly formed leg, presenting the appearance of the consolidation of two legs. There are eight toes on this limb, two of which have the appearance of great toes, being much larger than the others. Each has a well-formed head, good features, good chest, good arms and hands, lung, heart, liver, and stomach. Between the perfectly formed limbs, and properly situated are the anus and sexual organ in common. The lower portion of the bowels, the bladder, and, perhaps, the kidneys, are in common. All the other organs are separate. There was but one umbilical cord and one placenta. The length of the body is twenty inches, and the umbilicus is central in the abdomen, and equi-distant from each head. It nurses well at both ends, and, when first exhibited to the party, one child was asleep and the other was crying. While the physicians were making their examinations, both cried, but a few minutes after the one which was crying first went to sleep, while the other remained awake. When either head would cry, the perfect leg which was nearer to that head kicked and drew up, while the leg nearest the other head remained quiet. When either cried, the toes on the imperfect foot would move, but the limb remained stationary. Both heads nurse well, and the child, or rather children, are in excellent health. The physicians could see no reason why it, or they, should not live. The mother is doing well. There was no physician present at the birth, and the labour pains lasted only 15 minutes.

Gleanings.

Discovery of Anæsthetics.

The greatest delusion of modern times is the belief that Wells, and Morton, and Simpson, were the discoverers of anæsthesia. Proofs are produced almost every day that anæsthetic agents were known years and centuries before. Even Origen is quoted as having written, fifteen hundred years ago: "When the doctors wish to kill or burn people, they give a certain drink, which makes them sleep profoundly, so that they become senseless and thus feel nothing." * Perhaps we had as well end all vexatious controversy by putting a serious face on Professor Simpson's facetia, and dating the discovery in Eden, when Adam endured exsection of a rib while under anæsthetic influence.

Jesting aside, we see no use in exhuming every old *savan* who made a hap-hazard or enigmatical suggestion on this subject, and crowning him with the glory of a grand discovery. The application to human purposes is the point of value. What honour is there in proposing without attempting action? To conceive a grand idea and suffer it to die in the womb of the brain without practical application, is a very doubtful honour. How many thousands of persons suggested and believed that the earth was a sphere, before Columbus proved it? And how many conjectured and proposed that lightning was electricity before Franklin brought the spark from the cloud to his knuckle? The true heroes of science are those who do the work. Wells, Morton, Jackson, Simpson—let them all be immortalized; and let us not endeavour to tarnish their laurels by giving to the musty and misty.—*Pacific Medical and Surgical Journal.*

* "Quandovolunt medici incidere aliquos, vel urere, dan eis bibere aliquem potum, qui facit eos profunde dormire, ita quod amentes fiant, et sic non sentiant."

Cure for Sleep-Walking.

A LEARNED Professor of Florence has discovered that a copper wire, wrapped around the leg of a sleep-walker on going to bed, and left to extend to the floor, will prevent him from indulging in his ordinary pastime. He explains the result on electrical principles. We can readily imagine that a sensitive person, such as sleep-walkers are, would be kept from passing into the somnambulic condition by a *divcrticulum* of that kind. Many persons, not sleep-walkers, would not sleep at all with a wire coiled about their legs. The hint, however, is a good one. It is probable that sleep-walking occurs only in very sound sleep. Anything, therefore, which tends to prevent sound sleep, militates against the somnambulic manifestations. Unusual mental or physical impressions, made on going to rest, are calculated to have that effect. A person anxious to rise early, and fearful of over-sleeping himself, will lie awake half the night. There is some relation between sleep-walking and nightmare, both as to causation and prevention. Error of digestion may produce them, as a hard bed may cure. We have no doubt the wire would be as good against one as against the other. Perhaps a tarred rope would answer the purpose. Or what if the patient were to go to bed with his boots on?—*Pacific Medical and Surgical Journal.*

Renal Abscess, discharging externally for six years.

THE following case is reported by J. Stockton Hough, M.D., late Resident Physician to Philadelphia Hospital, in the *American Journal of the Medical Sciences.*

C. B., æt. forty-seven, was admitted into the Surgical Ward of the Philadelphia Hospital, March 17, 1869, at which time she suffered from a discharge of pus from an opening in the right lumbar region, just above the crest of the ilium, supposed to be due to the necrosis of the last-named bone. No other diagnosis had been made until the *post-mortem* examination revealed the nature of the affection.

She had been blind for eight years. At the time of admission she had also an ulcer on her leg, which was healed in five days. After this the quantity discharged from the abscess increased six ounces per day. She had not been confined to her bed until she came into the hospital. No difficulty in passing her water until the last two days.

This discharge of pus had been constant, though variable in quantity for a period of six weeks, increasing the last month. She died from pure exhaustion, four months after her admission.

The *post-mortem* examination revealed no other lesion than that of the kidney on the right side, which was enlarged, and contained numerous abscesses, in one of which was found a triangular calculus, about the size of a walnut. The fistulous opening was not direct, but quite oblique, admitting a fine probe, which probably struck the calculus and gave the impression that the bone was exposed, which led to the error in diagnosis. It is exceedingly rare to find abscess of the kidney discharging externally for so protracted a period.

Case of Congenital Absence of Uterus and Ovaries.

DR. S. HERTZ, reports this case in the *American Journal of the Medical Sciences.*

Miss E., æt, forty, unmarried, had always enjoyed good health till within the last year of her life. A few months previous to her death she came under my care for a slight dyspeptic disorder, which, on close examination, proved to be due to compression of the stomach consequent upon an enormously enlarged cancerous liver. There was nothing in the patient's general appearance indicative of serious trouble, and had not physical signs revealed the condition of the liver, it would not have been suspected. From the time she first sought medical aid up to the time of her death, three months afterwards, there was little in the patient's general aspect to occasion alarm, except the dyspnœa occasioned by the enlarged liver.

The *post-mortem* examination made by my friends, Drs. Barker, Darby, and myself, showed the liver to be greatly enlarged by cancerous deposit; stomach and intestines free from any deposit; kidneys somewhat enlarged and indurated. The chief point of interest, however, was a complete absence of the uterus and ovaries. The vagina was normal, both as regards length and capacity, terminating above in a cul-de-sac. The clitoris was well developed, together with the labia and mons veneris. The breasts were large and plump, the whole external aspect attested the attributes of a well-formed woman.

Fibro-Cystic Disease of the Ovary, with post-mortem Examination. By S. L. Blatchly, M. D.

IN the early part of April, 1866, I was called to see Mrs. M., in consultation with my friend, Dr. Strause. She reported some enlargement in the left iliac region, which had existed for about two years.

On examination we decided the case to be one of ovarian enlargement, from three to four inches in diameter. Nothing special occurred in the case, except a gradual enlargement, for some three years, when I was hastily summoned to the patient again, and found her in the most extreme agony. She said the tumour had broken, and she could feel the water moving in her bowels whenever she turned, and could not feel the tumour any more. Very great pain, tenderness, tension, and distension now existed, which precluded deep pressure on digital examination. Treated the case, for the time, as one of peritoneal inflammation. In five or six days the patient had much improved, and now with some difficulty I could discover the tumour, much smaller than before, and somewhat flaccid. Soon the tumour began to enlarge, and nineteen days after the first rupture a second took place, with a recurrence of all the unpleasant symptoms as detailed before. I again treated her as before, with like good effects.

She now had a short respite from her extreme suffering, of three to four weeks, after which the cyst again gradually filled, insomuch as to require paracentesis that some relief might be obtained, which was performed in the line of the linea alba, and six quarts of fluid removed, giving temporary ease. The cyst rapidly filled again, and the trocar introduced at the same point as before, but this time failed to enter the cyst, and the instrument giving the impression of passing into a fibrous body. Still hoping to relieve her sufferings, I again inserted my trocar into the left iliac region and drew off five quarts of fluid. The right side not lessening in proportion, after a few days I introduced the trocar into the right iliac region and removed about eight quarts more of fluid. During all this time there was evidence of more or less irritation and probable inflammation.

She gradually sank, and died in a few days.

Post-mortem nine hours after death.—In presence of Dr. Strause, Cary, and Sharp. The tumour was of fibrous character with numerous cysts of various sizes, containing dark bloody serum. On breaking up the adhesions between the tumour and the peritoneum, the tumour, intestines, spleen, pancreas, portion of liver, and stomach, were found agglutinated in one general mass.

On removing the tumour as best I could, and tracing it to its origin, it was found to have originated in the left ovary and Fallopian tube. The ovary was broken down in its central portion, and contained bloody pus. The fundus of the uterus was somewhat enlarged, and contained in its structure two fibrous tumours, 1¼ and ½ inch in diameter.

At the entrance of the left Fallopian tube there was a small sac of black grumous matter, and midway in the uterine canal there was complete stricture; right ovary somewhat diseased, omentum almost entirely absorbed, and the vessels of the abdominal viscera completely obliterated; liver studded over with small hard bodies of bony consistence; gall bladder largely distended; spleen and pancreas healthy, but completely adherent to the diseased structure; kidneys normal; bladder somewhat constricted; small and large intestines so completely imbedded in the tumour I could not separate them; lungs sound. The extensive adhesions in the case were, no doubt, the result of the spontaneous rupturing of the cyst, thereby causing more or less inflammation, which resulted in the remarkable and extensive adhesions. The *post-mortem* developments in this case, together with the phenomena following the spontaneous rupturing of the cyst, would seem to contraindicate any operation for the successful removal of the tumour, after such rupturing had taken place, inasmuch as the inflammation consequent on the operation, as also on the rupturing of the cyst, would compromise the life of the subject.—*American Journal of the Medical Sciences.*

Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on the 15th and 16th inst.:—William Allnutt, L.S.A., Portsea; George P. Applin, Addiscombe; George Ernest Archer, Feltwell, Norfolk; James B. Ball, Dublin; William Beatson, Camberwell; * J. Edwin Brooks, L.R.C.P. Edin., Silverdale; W. F. R. Burgess, L.S.A; John E. B. Burroughs, Lee, Kent; John S. Clarke, Liverpool; William E. Crowther, Hobart Town; William T. P. Douglas, M.B. Cantab, Banbury, Oxon; Francis H. Drake, Pontrefact; Edward B. Evans, Swansea; Hugh C. Fox, L.S.A., Stoke Newington; George C. Franklin, Leicester; William Garratt, Madras; Charles Gosse, Adelaide, South Australia; George J. Gray, Stonehouse; William Hammond, Howden, Yorkshire; Michael Harris, Hackney; Richard Harrison, St. Lawrence road; T. Scoresby Jackson, M.B. Edin., Whitby, Yorkshire; William J. Johnson, Worksop, Notts; Robert Jolly, M.D. and F.R.C.S. Edin., Birmingham; Frederick G. Larkin, Hoath, near Canterbury; * A. E. B. Love, L.S.A., Vauxhall bridge road; Henry C. Martin, M.B. Edin., Reigate, Surrey; Henry Morris, Queen's terrace; Malcolm A. Morris, Twickenham; John H. Mummery, Cavendish place; William M. Noott, L.S.A., Cardigan; * Edward W. Orton, L.R.C.P. Edin., Coleshill, Warwickshire; Henry D. Palmer, Olney, Bucks; William Ritchie, M.D., Dublin; Eleazar B. Roche, Norwich; Charles Lyon Vasey, L.R.C.P., Cavendish place; George E. Walker, Quorndon, Leicestershire; Henry Wotton, Plymouth. Seven other candidates were examined on the above-named days, but failed to satisfy the Court, and were referred for a period of six months' further professional study.—[* Passed in Surgery at previous meetings of the Court, and, having subsequently obtained medical qualifications recognised by the College, were admitted Members.]

University of London.—Pass List.— Second M.B. Examination.—*First Division:* Messrs. Edgar G. Barnes, St. George's Hospital; John Mitchell Bruce, M.A., University of Aberdeen; William Frederick Richardson, John De Liefde, Arthur William Smith, Guy's Hospital: Charles Henry Carter, B.A. James Pearson Irvine, B.A., B.Sc., Richard Lawton Roberts, University College; John Curnow, King's College; Charles Henry Joubert, St. Mary's Hospital; Frederick Pollard, St. Thomas's Hospital.—*Second Division:* Charles Taylor Aveling, St Thomas's Hospital; Ashley William Barrett, London Hospital; Alfred Cotterill, Alfred Thomas Gibbings, Charles Tanfield Vachell, William Beach Whitmore, King's College; James Alfred Harris, Edinb. Univ. and R. Coll. of Surg.; Walter George Lowe, St. Bartholomew's Hospital; Rushton Parker, William Price, Alfred Shewen, University College.

The late Miss Eleanora Atherton, of Quay street, Manchester and of Great James street, Middlesex, has left the following charitable bequests to medical institutions:—£1,000 to St. Mary's Hospital, Quay street, Manchester; £1,000 to the Manchester Royal Infirmary and Dispensary; and £500 each to the Eye Infirmary, Manchester; Asylum for Idiots, Earlswood; Royal Hospital for Incurables, Putney; and the British Home for Incurables, Clapham rise.

A Course of Lectures will be delivered at the Hospital for Women, Soho square, on successive Thursday evenings during the months of January, February, and March to practitioners and students. Dr. Protheroe Smith will lecture on "Flexions, Tortions, and Displacements of the Uterus," Dr. Alfred Meadows on "Uterine Hyperæmia," and Mr. Christopher Heath on "Diseases of the Breast." Students may obtain cards of admission on application to the Secretary at the Hospital. Medical Practitioners will be admitted on presenting their card.

East London Hospital for Children.—This institution has received most timely help by a donation of £1,000 from G. H. Had it not been for this liberal gift the committee would have been compelled to sell stock to meet current exqenses, and so encroach upon a sum of £1,500 set aside as the commencement of a fund for erecting a new hospital.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

*** We must also request our Correspondents to write only on one side of the paper and in *legible* characters. We are often compelled to consign MSS. to the waste-paper-basket merely because it is illegible.

Correspondents not answered in the current Number are requested to look to the Notices the following week.

To Subscribers.—The publisher has received a Post-office Order for £2 5s., without the name or address of the sender, who would oblige by forwarding it to the London office, that credit for the amount may be given, and a receipt sent.

Dr. Bolton.—Enclosure received. The gentleman named is duly qualified and registered. This answer has been forwarded to the address whence the enquiry emanated.

Newspaper Decisions in America.—1. Any person who takes a paper regularly from the post-office—whether directed to his name or another's, or whether he has subscribed or not—is responsible for the payment. 2. If a person orders his paper discontinued, he must pay all arrearages, or the publisher may continue to send it until payment is made, and collect the whole amount, whether the paper is taken from the office or not. 3. The courts have decided that refusing to take newspapers and periodicals from the post-office, or removing and leaving them uncalled for, is *prima facie* evidence of intentional fraud.

MEETINGS OF THE LONDON SOCIETIES.

Friday, the 25th.

Clinical Society.—3½ P.M. Mr. Brudenell Carter: "Case of presumed Injury to the Ciliary Nerves from a Blow." Mr. Durham: "Remarkable Case of Spontaneous Fracture of Femur." Dr. Wiltshire: "On Paroxysmal Hæmaturia." Dr. Handfield Jones: "A Query as to the Safety of Subcutaneous Injections." Dr. Silver: "On the Use of Veratrum Viride in Acute Rheumatism."

Quekett Microscopical Club.—8 P.M. Mr. Wm. Ackland: "Notes on a New Selenite Polarising Film." A Practical Demonstration in Microscopical Injection.

Monday, the 28th.

Medical Society.—8 P.M. Ordinary Meeting.

VACANCIES.

Cork North Charitable Infirmary.—House-Surgeon, and Resident Apothecary. Salary £100, with apartments, &c. (See advertisement).

Lincoln County Hospital.—Assistant Medical Officer. Salary £120, with board and residence.

St. Marylebone, London.—District Medical Officer. Salary £120.

West Derby Union.—Assistant Medical Officer. Salary £80 first year, £100 the second, with board and residence.

Evesham Union.—Two Medical Officers. For the Muker district, at £48 per annum, with extra fees, and for the Pebworth district. Salary £12, with fees extra.

Gnilsborough Union.—Medical Officer. Salary £35, with extra fees.

Stockport Infirmary.—Assistant House-Surgeon. Salary £50, with board.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Dr. Syson's Pamphlet on the Contagious Diseases Act.

Irregularität und Krankheitender Zaine. By Henry Sewill, M.R.C.S.

Odd Showers. By Carriblier. London: Kerby and Son.

The Physiological and Medical Aspect of Sewage Irrigation. By Alfred Carpenter, M.D. London; Robert Hardwicke.

Una Visita Agli Ospedali di Londra. By Dr. C. Mazzoni.

Experiments on some Infusions of the Pharmacopœia. By J. B. Barnes.

American Journal of the Medical Sciences; Woodhull's Weekly New York; New York Medical Journal; Glasgow Med. Journ.; The Chemist; New York Med. Gaz.; and Boston Med. Journ.

Marked Newspapers.—The Observer; Exeter Gazette; Coventry Herald; Scarborough Gazette; Mansfield Times; Lincoln Journal; Cardiff Times.

APPOINTMENTS.

Ashe, Isaac, A.B., M.B., Ch.M.T.C.D., Visiting and Consulting Physician to the County Donegal Lunatic Asylum; Surgeon to the Prince of Wales's Donegal Artillery Militia; Physician to the Letterkenny District Fever Hospital, and to the Letterkenny Dispensary and Constabulary.

Baumgaertner, J. R., Resident Accoucheur to King's College Hospital.

Campbell, A. C., M.B., L.R.C.S.Ed., Surgeon for the West District of the Dundee Royal Infirmary and Dispensary.

Chittenden, C. P. D., L.R.C.P., Resident Obstetrical Officer at Charing Cross Hospital.

Crean, Richard, L.K.P.C.P.I., L.R.C.S.I., House-Surgeon at the Clayton Hospital and Wakefield General Dispensary.

Curran, J. Waring, L.K.Q.C.P., L.M., &c., Poor-law Medical Officer for the Mansfield Woodhouse District of the Mansfield Union.

Greene, W., L.R.C.P.L., M.R.C.S., House-Surgeon to the Queen Adelaide's Dispensary, Bethnal green road, London.

Hayes, T. C., L.S.A., House-Physician to King's College Hospital.

Holmes, Dr. H., Medical Officer for the Dunamanagh Dispensary District of the Strabane Union, Co. Tyrone.

Hughes, W. R., L.R.C.S.I., Assistant House-Surgeon at the Birkenhead Borough Hospital.

Lett, F., L.R.C.P.Ed., M.R.C.S.E., Junior House-Surgeon to the Royal Free Hospital, Gray's-inn road.

LITTLE, W., LRCP, M.R.C.S., Senior House-Surgeon to the Liverpool Southern Hospital.
NOAKES, S. S., Resident Medical Officer at Charing-cross Hospital.
ROBINSON, J. D., Resident Surgical Officer at Charing-cross Hospital.
ROPE, H. J., M.R.C.S., House-Surgeon to King's College Hospital.
WESTMORELAND, J., Medical Officer No. 4 District of the Manchester Union.

Marriages.

ALLFREY—SMITH.—On the 10th inst., at the Parish Church, Maidstone, Charles Henry Allfrey, M.D., F.R.C.S.E., of St. Mary's Cray, to Emily Malden, daughter of Thomas Heckstall Smith, F.R.C.S.E.
SINCLAIR—WALTON.—On the 15th inst., at Dalton-in-Furness, William Sinclair, M.D., of Barrow-in-Furness, to Mary, only daughter of the late Rev. Henry N. Walton, of Ireleth, Lancashire.

Deaths.

FRANKS.—On the 15th inst., in London, Moses Franks, M.R.C.S., aged 68.
ROBERTS.—On the 9th inst., Dr. Wm. Lloyd Roberts, of the Hospital, Festiniog, aged 26.
TUBBS.—On the 11th inst., in London, William John Tubbs, Surgeon, of Upwell, Cambridgeshire, aged 59.

Original Communications.

ON SOME CHRONIC VARIETIES OF SYPHILITIC ULCERATIONS.

By Mr. Morgan, F.R.C.S.I,

Surgeon to Mercer's and to the Westmoreland Lock Hospitals; Professor of Surgical and Descriptive Anatomy, R.C.S.I.

A Peculiar Form of Venereal Ulceration.

The resemblance between some forms of chronic ulceration of a venereal origin, and that of an epitheliomatous nature is very remarkable, and may be the source of deep anxiety both to the surgeon and the patient; the persistence of the ulcerations, their appearance, and character, at times, almost completely simulates a malignant character, especially that form of ulceration, seen for instance on the face, as "Jacob's ulcer," where the progress is slow, the margin cuticular, and peculiar; and where the absence of pain and of glandular enlargements lull the patient's anxieties. Some cases both of pseudo-malignant ulcerations and growths have lately come under my notice, which I can best illustrate by detailing a few of the instances which have been noted with as great accuracy as could be obtained.

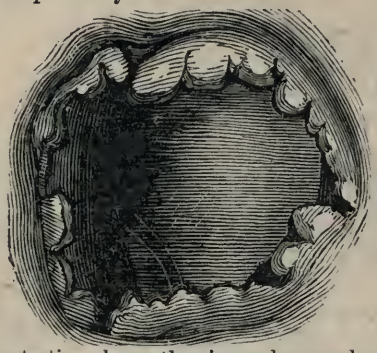
A patient, aged thirty seven (No. 824), was admitted to the Westmoreland Hospital, January 4th, 1870. She still has the appearance of being strong and in tolerable condition, and gives the following history which has been confirmed by reference to the hospital books. She has no recollection of any primary sore, but had gonorrhœa —*i.e.*, discharge several times; about six years ago an ulceration, manifestly of a secondary character, attacked the mouth, ending in a cicatrisation which closed the aperture to about one-half. This I repaired by operation, excising the cicatrised portion, and detaching and draining out the mucous membrane around the margin of the incisions. She had no further symptom, but suffered from pains rather severely. About five years ago a small sore formed at the nympha which has never healed since, but has gradually extended in a serpiginous course around the vulva. For the first two and a-half or three years, she continued an irregular life, but has since been obliged to desist, owing to the irritation. The sore has a superficial, very faintly granular appearance, with hardened edges, creeping irregularly around—the nympha, clitoris, and inner side of labia have been occupied by it. There is a little ichorous thin discharge from it—microscopically containing a few pus cells and copious epithelium. The margins are in places as if gouged out sharply and superficially; and there is no uterine or intra-vaginal ulceration whatever. The inguinal glands are healthy, and the condition of the patient almost in robust health. There is no sign whatever of any other constitutional evidences of infection.

Auto-inoculation of the sore, repeatedly tried, failed. The patient never had taken mercury in any shape. It is known from reference to the hospital books that the sore has existed now nearly five years.

A drawing taken bears the strongest resemblance to a malignant erosive ulceration.

The treatment consisted in the free application of escharotics, the local use of an arsenical lotion, and the administration of Fowler's solution, perseveringly—the ulceration healed in parts and cicatrised over. The patient left hospital before its being entirely healed, and has returned on several occasions since, suffering from the same form of ulceration but in a minor degree, the appearance and condition being still entirely free from any malignant cachexia. Whether this sore was capable of propagation as a venereal affection there is no evidence to show; it was certainly not auto-inoculable on several occasions; if communicable, it would easily explain how

venereal disease may be propagated extensively, and for a continued period by one individual.



The illustration shows the size and general outline.

Chronic Ulcer of Another Form.

Another variety of chronic sores is not at all unusual, but they differ from that which forms the subject of the foregoing remarks. They are surrounded with a dense cuticular and callous edge, and secrete a little, thin ichorous discharge; they appear to be very insensible, and are totally devoid of granulations. Their existence dates from one to three years. They resist *auto*-inoculation, but being usually associated with well marked constitutional signs, there is little doubt of their possessing viridity of a dangerous form to the system; they sometimes co-exist with other more recent sores, as in one of the following instances :—

No. 963. Admitted March 16th, 1870. Aged 30. W. 6.	Large chronic sore at the vaginal orifice, of 18 months' duration; five smaller pus secreting sores on the labium and nympha; papular rash.	Had pains, mucous patches, and discharge.
No. 768. Admitted December 7th, 1869. Aged 30. W. 12.	Chronic sore for two years at vagina; scattered papular rash; cachexia.	Had a sore and rash three years before. Died of phthisis and cachexia.
No. 733. Admitted November 17th, 1869. Aged. 30. W. 14	Large chronic sore of nympha; two years' duration.	Never had rash but severe pains.
No. 735. Admitted November 17th, 1869. Aged 25. W. 14.	Large chronic sore of two years' duration at vaginal orifice.	Had discharge, pains, papular rash, and lost one eye by untreated iritis.
No. 1,018. Admitted March 29th. Aged 20. W. 6.	Had for the last 18 months a huge chronic sore of the nympha; now has a large non-indurated sore at fourchette, almost phagedenic in character.	Has the cicatrix of a healed chronic sore; has pains only.
No. 749. Admitted Nov. 25th, 1869. Aged 22.	Has a large chronic sore on the nympha, which is unusually hypertrophoid.	Four and a half years ago had a sore and patches; never had rash, pains, or bubo.
No. 1,016. Admitted March 29th, 1870. Aged 28. W. 6.	Extensive ulcerations of the nympha and hypertrophy; cachexia extreme.	Two and a half years ago had a suppurating bubo, and in one year got the present sore.

We find, thus, the chronic sore in these instances associated with various evidences of constitutional infection. In one case, 740, there has been, however, no constitutional evidence.

That they are capable of communicating true syphilis, I have been able, from circumstances, to be fully well satisfied of, as I have had lately an instance proving the sad effects of contact with this form of sore, which has come under my notice, and which strongly proves the incalculable mischief which the sufferers from such chronic sores can inflict.

A married woman applied at the hospital, and gave the following evidence. She had been married some three years; her husband, who had been industrious and well behaved, admitted that he had diseased her. She was suffering from a copious roseolar rash, severe pains, and profound cachexia, and had a ragged soft sore, and some mucous patches at the vulva. She finally became so prostrated as not to be able to stand, and suffered from most severe cachexia and nocturnal pains.

The husband submitted himself to examination. He had a sore equalling sixpence in size, non-indurated at the base, but with a red and non-secreting surface of ulceration; he was covered with roseola, and suffered from pains, and had no inguinal enlargements whatever; he admitted that he had connection with No. 735, mentioned in the foregoing list of cases (who has had a sore upwards of two years), and was infected by her, the sore appearing within one week, and he, in turn, infected his wife.

Thus, a chronic sore with smooth surface and indurated and welty edge, is capable of producing a non-secreting sore on the male, which, in turn, produces a non-indurated one in the female; but all three have copious evidences of syphilitic infection.

In some rare instances of the formation of this chronic sore, as No. 794, doubtless the evidences of constitutional taint are by no means marked, but usually they are distinguishable.

If any proof based on practical observation were wanting, as to the non-existence of the fine-drawn distinctions so written about, between soft secreting but non-infecting sores and the hard non-secreting and infecting, such instances as this are tolerably conclusive.

Here the sore in the male on the prepuce was totally devoid of induration, but was red and non-secreting—without the slightest enlargement of the inguinal glands, while in the wife, the sore was soft, ragged, and pus secreting, and associated with mucous patches, and there was slight enlargements of the inguinal glands. Both husband and wife were thoroughly infected, while the origin of both was a sore of two years' duration, of an indolent non-secreting character, were constitutional signs were evident.

Another instructive instance lately occurred in a man and wife. The man had an indurated sore on the dorsum of the penis of three months' duration, yet he was inoculated from it on the abdomen, and had papular squamous rash and pains; he infected his wife, but she got a large ragged sore at the fourchette, with tender almost suppurating inguinal glands, iritis alopecia, papular rash, and became profoundly cachetic. Over and over I have tested soft secreting sores by inoculation, yet they were followed by intense constitutional signs, on the other hand, the few instances of indurated sores that occur from time to time, have been characterised by the mildness of the succeding signs..

IN-GROWTH OF THE TOE-NAIL.

By J. Waring-Curran, L.R.C.S.I., L.K. Q.C.P.I., &c.

The general treatment of ingrowing toe-nail which is always tedious and frequently troublesome, it is not my intention to review, but as briefly as possible to explain a form of treatment which I have practised for the last

three years with uniform success, or, to be accurate, with that amount of success which may be expected resulting where evulsion of the toe-nail is not resorted to, and where, I think, I shall presently show the necessity of performing that simple, though painful, and disagreeable operation, was in several instances overcome. The first four of my patients were cases wherein I had exhausted my experience and book-learning, in order to prevent, if possible, evulsion; but there was little improvement; the cases did not progress as would have been desired; accordingly, I took advantage of a fortunate incident in trying a new method of treatment. At the house of a literary friend, I met an Italian lady, whose high attainments and publications are well known in literary circles. After discussing various topics, in conversation, we entered upon the very remarkable one of "filbert nails," which she told us were cultivated by the ladies of her native town to such a degree that they ignored the wearing of gloves, in order to exhibit the neatness and symmetry of the finger nails. She told me, in order that they may be properly grown, chiropodists, practising the art of nail cultivation, were in the habit of putting their consultees under the following plan of treatment. Out of the centre of the nail they cut a triangular portion—the base at the free extremity of the nail, and the apex at the matrix—so as to encourage the nail to contract from the edges towards the centre; or, in other words, to make the central part of nail grow with greatest prominence. Having three chronic cases of in-growing toe-nails in the district, I bethought me to try the plan of cutting out a triangular central portion, with a very wide base, shaving the edges of the in-growth as thin as expedient with a piece of glass, and tying the separated nail together loosely with a piece of dentist's silk from beneath, and placing between the nail and contiguous soft parts, into which the nail intruded, a piece of thick worsted, coated with mercurial ointment. Where those exquisitively-sensitive granulations existed, I applied some extract of belladonna and resin ointment rubbed together, and adopted the same method in remedying the shape and growth of the nail.

In the course of time the affected nail assumed a better shape, grew out more prominently, and away from the sides, whilst the pain and irritation was overcome by the belladonna application, and eventually cured by the mercurial ointment, and pressure taken off by the better shape assumed by the nail.

As against every method of treatment, which has for its object the cure of in-growing toe-nail without evulsion, it may be said, my plan needs much patience, and requires time and perseverance. The patients were only too glad to have something to do, and to practice it, for there is a great antipathy among them to tearing out the nail by the forceps, even under chloroform. I ignore the ether spray, for I have used it in removing a toe-nail, and should be sorry to depend on its pain-destroying virtues in future.

Nails, thus operated on, acquired a normal shape in six months; whilst in from six weeks to three months, according to the existing severity of mischief in the soft parts surrounding the nail, the toe became healthy. I insisted on the wearing of broad toed shoes with low heels, that the foot should not be thrown too prominently forward, or the toes be unduly compressed together.

In two of my patients the outer side of toe-nail had overhanging soft parts which appeared healthy on the surface, but into which the nail was growing; these I shaved off with a bistoury, lifted the nail, took out the triangular portion and, by stimulating applications, got a flat, healthy surface, which soon skinned over.

It may be readily gathered what I mean to show is that a central portion cut out of the nail will alter the shape of that nail, and, if the disease in the soft parts be attended to, will be found of great practical utility in treating, and altering the shape of, an in-growth of the toe-nail.

CLINICAL MEMORANDA.

SOME AFFECTIONS OF THE NERVOUS SYSTEM ASSOCIATED WITH PREGNANCY.—CHOREA, ATTENDING PREGNANCY. — HEMIPLEGIA, FOLLOWING DELIVERY.

By Thomas M. Dolan, L.R.C.P.E., L.R.C.S.E.,
Medical Officer of the Halifax Union Infirmary.

Chorea, attending pregnancy, may be looked upon as a comparatively rare affection, though we find it mentioned by various writers on nervous diseases, and cases of the kind have been recorded by obstetricians.

The distinguished Berlin Professor, Romberg, in his work "On Nervous Diseases" (Sydenham Society Edition. Vol. 2. Page 60 to 63), gives the record of three cases observed by himself, and an analysis of five recorded by Dr. Lever in the *Guy's Hospital Reports*. The following well-marked case seems worthy of publication, as it illustrates the influence of the sexual organs in causing what has been called "insanity of the muscles," as the choreic symptoms began with the suppression of the catamenia, continued whilst pregnancy was advancing, were aggravated during labour, and then gradually disappeared. It also shows the value of chloral hydrate in producing sleep, for the want of it is oftentimes one of the most distressing symptoms of this complaint, and the physician's best efforts are generally taxed to procure a remedy to induce it.

Sarah Ann Whitely, twenty-one, married, mill-hand, was admitted into Halifax Union Infirmary, May 9, 1870, suffering from chorea. She was about seven months advanced in pregnancy; the choreic movements beginning upon suppression of the menses. She believed she had a like attack when five years old. The motions were incessant and general. There was great contortion and twisting of the features; articulation was impeded; she was very much debilitated and weakened, as for several weeks she had very little sleep, and her appetite was very bad; her pulse was weak; tongue flabby and swollen, and marked with numerous indentations; her bowels very much confined. She was ordered into the long sick room, and an aperient dose given, and she was placed upon No. 6 diet, which consists as follows:—

Breakfast.—Five ounces of bread and pint of milk. *Dinner.*—Five ounces of bread and pint of beef tea. *Supper.*—Five ounces of bread, pint of milk; a liberal allowance of wine was also given. The first essential point was to procure sleep, and thus to enable her to make up for the increased waste of tissue going on. Our usual sheet-anchor could not be resorted to, for, according to one of our best medical authorities (Tanner), "In chorea, opium is useless; it may be given until the pupils are contracted, without lessening the irregular movements."

Chloral hydrate seemed likely to be the therapeutic agent to be relied on, and I decided on trying it. The first night she had fifteen grains, to be repeated in four hours if necessary. Both doses were given, but the effect was very transitory. I increased the dose to twenty grains with better effect. She slept for some hours, though the nurse informed me that the movements continued whilst she slept. During the day she took a mixture, containing half-drachm doses of bromide of potassium. A medical friend, who saw her with me, suggested that chloral hydrate might have some injurious effect on the fœtus—I, therefore, listened each day for the sound of the fœtal heart, and found it unimpaired. Each night, for a fortnight, she took twenty grains, when I tried her without it, and found she slept very well; her appetite was now improved, and I placed her on No. 2 diet, as follows:—

Breakfast.—Five ounces of bread and pint of milk. *Dinner.*—Eight ounces of potatoes, five ounces of bread, six ounces of meat. *Supper.*—Five ounces of bread and

6

pint of milk, and as some of my other patients were beginning to imitate her, she was removed to the Lying-in ward. On making several examinations of the urine, I found the specific gravity always high, and it was abundantly loaded with urates. There was no history of rheumatism, and her heart sounds were normal. Her health continued to improve, the movements to be confined chiefly to her hands, and she was able to go out and take some exercise. On June 27th, she complained of some pains in her back and loins; when the choreic symptoms were aggravated, she tossed about the bed incessantly, and her articulation was very much impaired. On vaginal examination, I found that labour was setting in. Pains came on very rapidly; the os dilated easily; the liquor-amnii did not escape until a few minutes before the birth of the child, and after a labour of about four hours' duration, she was delivered of an apparently healthy boy. She gradually improved each day; the movements diminished. She was put on sulphate of zinc mixture, cold shower bath, and was discharged quite well on the 3rd of August.

Hemiplegia following delivery.—The occurrence of paralysis before, during, or after labour, in many of our midwifery works is passed over, or but slightly mentioned; though in the work of Churchill considerable attention is given to the subject, and it is there treated with that painstaking research which distinguishes all the writings of the Dublin Professor. He has collected together a mass of valuable material, illustrated by cases which cannot fail to assist those who may meet with such in their practice. Romberg also, in his monograph, has given attention to the subject.

The following case presents some features of interest, as the attack was sudden and unexpected, and uncomplicated by any impairment of the mental faculties.

Mrs. S., Fleet street, Halifax, was attended by me for her first confinement in July, 1870. She was about twenty-one years of age, strong, healthy, but of very full habit. There was nothing particular about the labour. The pains were very strong and continuous, and after being with her only about two hours, she was delivered of a fine boy. Once or twice she complained of feeling very chilled, although she was perspiring very freely, on the side now affected. I saw her twelve hours afterwards. I noticed that her mouth was slightly twisted to the right side. In reply to my questions, her speech was thick and inarticulate; her tongue was turned to the same side; her right arm and leg were deprived of power and motion, but sensibility was undiminished. She said she felt very well, but was quite aware that such was the case. She complained of no pain anywhere; had no confusion of thought, and the pupils were unaffected. She had fallen asleep, and woke up in the condition I found her in. I ordered her to be kept very quiet; had her bowels well opened, and stimulating liniments applied to arm and leg; and in order to assist the action of the skin and kidneys, I ordered her a saline mixture. The milk came freely on the third day; tongue continued clean and moist; pulse very fair; she made water freely; and the discharge was very free. She very soon complained of not getting enough to eat, and wanted to get up on the sixth day. The child was weaned, and on the eighth day I placed her on strychnia, and on the ninth day when I called to see her, I found her sitting down stairs, but she could not walk or move the right arm. Her general health continued good; she ate and slept well, and seemed in very good spirits. I still continued the same treatment for some time, when she told me that she would not take any more medicine, and though far from being well, I was compelled to cease my attendance upon her. On making examination of her urine I found it albuminous.

The above case opens out to us a wide field of speculation as to its cause. Had there been any serious cerebral mischief, we should naturally expect some impairment of the mental faculties, and confusion of thought, or loss of memory; and we can hardly suppose that the hemiplegia depended upon spinal causes. The hypothesis of Churchhill and many other very eminent obstetricians, that albuminuria has some part in producing these important lesions, affords us some solution of the difficulty of assigning a cause.

On the day of her confinement, the air was close and hot — she perspired very freely, and, as before mentioned, she complained of feeling very chill and cold; and the checked skin action may have produced some congestion of the kidneys, ultimately terminating in paralysis.

Transactions of Societies.

THE MEDICAL SOCIETY OF LONDON

MONDAY, NOV. 21ST, 1870.

JOHN GAY, Esq., President.

Mr. CLEMENT GODSON brought forward

PART OF A FIBROUS POLYPUS REMOVED FROM THE ANTERIOR WALL OF THE VAGINA OF A WOMAN, AGED THIRTY-TWO YEARS.

The polypus was removed by the wire écraseur ten days ago, no pains or hæmorrhage took place, and the patient made an excellent recovery.

Mr. DAVY showed a plan he had devised for the more easy and speedy removal of the skull cap at *post-mortem* examinations. A screw fitted to a T shaped handle was introduced into the vertex, then a grasp of the handle enabled the operator to keep the head steady while he screwed through the skull. Mr. Davy's plan was to use a saw with a moveable back, with which he sawed through skull and brain at once. After washing with water, a good section of the brain was then obtained.

Mr. STREETER thought this much too coarse a procedure where the brain had to be minutely examined.

Dr. SUTTON sometimes sawed through brain and skull together, but not when a careful dissection of the brain was required.

Dr. BLOXAM approved of Mr. Davy's method of fixing the skull, he considered it very desirable to open the skull by sawing, and not by hammer and chisel, more especially, in cases of suspected fractures at base of skull.

Dr. JOHN MACPHERSON then read the paper of the evening,

ON THE ANALOGIES OF CHOLERA NOSTRAS, AND CHOLERA INDICA.

After pointing out the diseases with which Cholera has been confounded, it was shown by a historical sketch, that Cholera Nostras had often been epidemic in Europe, and some of the opinions respecting it were mentioned. It was shown that the symptoms of two diseases during life resemble each other closely, and as yet no difference has been found between them. *Post-mortem.*—The indications for treatment are the same in both. The two affections have been ascribed to the same predisposing and existing causes. It was shown that they have the same character of reason and prevalence, and that they both exercise a distinct action on other diseases. Contagiousness has been attributed to both, neither gives immunities against future attacks. A relapse or a repetition of the disease may occur in either, from imprudence, both have been compared to acid poisoning. The existence of a poison in both has been suspected, supposing the poison of Cholera Indica to have been discovered, then might remain one to be discovered for Cholera Nostras. For the present, their leading differences are of degree. Cholera Indica has increased intensity of symptoms, and increased power of spreading. A few points of analogy with other diseases were also pointed out.

Dr. SUTTON endorsed all that had been said as to the symptoms. At one time Dr. Sutton thought he could distinguish between English and Indian cholera. Sudden violent invasion, rice-water stools, and a temperature rising above 100°, he at one time thought to be characteristics of Cholera Indica, but in the years 1868-69-70, he had met with three cases of English cholera that disproved the hypothesis. Some thought cramp in the calves of the legs as well as in the belly to be characteristic of Indian cholera, but cases of English cholera had disproved this. One case of English cholera was seen by Dr. Sutton last summer that had all the character of epidemic Indian cholera. The

patient had come from Italy, and was taken suddenly in London with vomiting, rice-water stools, temperature over 100° collapse and death. English cholera generally ended in recovery, and death from uncomplicated diarrhœa, Dr. Sutton thought to be rare.

Mr. RADCLIFFE said that had the case quoted by Dr. Sutton come from St. Petersburgh last summer, it might have been imported Indian cholera.

Mr. BARNES had seen cases of cholera in 1849 and in 1854, he asked Dr. Macpherson if he had seen trismus and tetanus accompany cholera, for he had observed trismus in some cases.

Dr. MACPHERSON had not seen this complication in cholera, but was familiar with it as not being rare.

Dr. WALLER LEWIS never knew a case of cholera that was not preceded by premonitory diarrhœa, and it was in detecting and checking this symptom, that a system of house to house visitation had proved so eminently successful.

Dr. BLOXAM believed it to be very rarely that cholera was preceded by diarrhœa; in 1849 one of the first cases that occurred, was that of a man found dead in the park, there was no evidence of diarrhœa, but his intestines were full of rice-water fluid.

Dr. MCOSCAR saw much of cholera in 1854: one case was that of a man seized suddenly with violent vomiting, he died in an hour without any diarrhœa.

Dr. SEMPLE agreed with Dr. Sutton, that cases did occur where English cholera presented all the characters of the Asiatic disease. He, however, believed the two diseases to be distinct. English cholera was an undue flux from the mucous membrane. Asiatic cholera was due to a poison acting on the nervous centres, and causing decomposition of the blood, the serous part of which was evacuated as rice-water stools by the bowels. Cases of English cholera were always met with sporadically in the summer months.

Dr. SIMMS suggested, that whether was it possible that Cholera Indica might have developed from Cholera Nostras originally.

Inspector-General LAURENCE had seen many epidemics of cholera. In 1836 there was a severe epidemic of cholera in Sicily, he was at that time at Malta, and they had many cases of Sporadic Cholera Nostras.

Dr. MACPHERSON briefly replied, and the meeting adjourned.

CLINICAL SOCIETY OF LONDON.

THIRD MEETING, NOV. 11th.

Mr. PAGET, President, in the Chair.

SKIN GRAFTING, AND SKIN TRANSPLANTATION.

MR. POLLOCK read particulars and exhibited several cases of Skin-grafting and Skin-transplantation. In relating the particulars of the first case in which skin-grafting had been attempted in this country, he stated that in 1869 M. Reverdin originated in Paris this method of treating large ulcerated surfaces. In May, 1870, the author first heard of M. Reverdin's experiments, and at once decided to test the treatment. A girl, eight years of age, had been in St. George's Hospital for some three months and a-half, with an extensive open burn of the right thigh, of more than two years' duration. The ulcerated surface extended from the buttock to the knee—broad above, and ending almost in a point below. Mr. Pollock at first transplanted two small pieces of skin about the size of millet seeds, taken from the lower part of the abdomen. Subsequently three, and again other pieces, were transplanted at various periods—in all, about fourteen pieces had been transplanted. The child was exhibited to the members of the Society, and it was seen that this extensive burn was nearly healed, in a period little over five months, without any perceptible contraction of the cicatricial tissue originated by the transplanted skin. The child had greatly improved in health as the progress of cicatrisation had advanced. In this case two pieces of black skin had been on one occasion transplanted to the ulcerated surface, and became attached; when increased in size, the area of the pigment deposit had considerably increased in one of them, although the whole of the cicatricial tissue due to the transplantation of this portion of skin was not generally dark coloured. The sore was attacked some time after by sloughing, which was chiefly confined to the portion in which the black skin had been engrafted, and unfortunately destroyed the whole of the cicatrix due to this transplantation. Mr. Pollock made some general remarks with respect to the mode of transplantation, and the conditions requisite to the success of the operation. He usually transplanted very small pieces, similar to the plan pursued by M. Reverdin, and considered it essential to the success of the operation that the surface of the granulations should be in a healthy state. In some cases the operation had entirely failed, in consequence of the state of the sore. In other cases, though the piece transplanted had become attached and vitalised, yet, owing to the state of the patient's health, it had remained stationary, and gave no sign of increase. Mr. Pollock in conclusion, thought a tribute of admiration and gratitude was due to M. Reverdin from the profession for the boon he had conferred upon surgery by the introduction of this original method of dealing with large and obstinate ulcers.

Mr. LAWSON read a paper "On the Successful Transplantation of Portions of Skin for the Closure of large Granulating Surfaces." He exhibited two patients in whom this mode of treatment had been attended with satisfactory results, and related the history of a third who had been equally benefited by the method of transplantation. In one patient a large ulcer of the leg, which had resisted all treatment for over four years, was completely closed in a few weeks after a piece of skin the size of a fourpenny-piece had been planted on it. As soon as the new skin had established its vitality, granulations sprang from the circumference, and rapidly closed-in the wound. In another patient the results were equally satisfactory. In a third case Mr. Lawson formed a new eyelid for a patient who had a complete ectropion of the upper lid. He dissected the lid from its attachments, pared at two points the corresponding tarsal margins, and united them by two fine sutures, and thus obtained a fixed level surface upon which to transplant a portion of skin. The parts were then left, and on the fourth day, when the wound was covered with healthy granulations, he transplanted a piece of skin of the size of a threepenny-piece, and two days later another portion, of the size of a silver fourpenny. Both pieces rapidly united to the granulating surface, and the space between them was speedily filled up with new cicatricial tissue. A new lid was thus formed, which was sufficient to protect the eye from exposure; but the presence of two pieces of skin, different in appearance to the ordinary eyelid integument, gave to the patient a peculiar and rather unsightly look. In each of these patients the skin which was engrafted not only soon became vascular, but acquired sensibility, and after ten or twelve days could appreciate the slightest touch with a blunt instrument. The conditions which Mr. Lawson found essential for the operation were:—1. That the new skin should be applied to a healthy granulating surface. 2. That skin *only* should be transplanted, special care being taken that no fat adhered to it. 3. That the portion of skin should be accurately applied to the granulating surface. 4. That the new skin should be kept in position without interruption, and that it should be lightly covered with a layer of lint, and over that a small compress of cotton wool, and a bandage, for the purpose of maintaining its warmth, and thus to assist in retaining its vitality until it had established its new life.

Mr. CROFT mentioned a case in which he had transplanted a piece of skin a quarter of an inch square on to a large granulating sore of the leg. Eleven days afterwards it had doubled in size, and was now progressing very quickly towards recovery.

Mr. FRANCIS MASON remarked that the size of the pieces which were transplanted was worthy of special consideration; that, according to his own experience, pressure was important, and he regarded several failures that had occurred as due to the difficulty of obtaining this condition satisfactorily, on account of the situation of the parts treated.

Mr. CARTER asked Mr. Lawson if a better result might not have been obtained by transplanting a small piece from the other eyelid, so as to preserve the natural delicacy of the skin of the parts.

Mr GANT agreed that the similarity of texture on both sides of the body was worth recollecting in these cases.

Mr. SPENCER WATSON gave brief particulars of cases that had come under his notice at the Great Northern Hospital, and considered that the success of the operation depended very much in keeping the transplanted pieces in position.

Mr. HENRY ARNOTT spoke of a case in which two ulcers existed, one having been treated by transplantation and the

other left alone; both closed pretty much at the same time; and, in reply to Mr. Heath, said that the case was one of keloid, following a burn.

Mr. Reeves thought that large pieces of skin should be transplanted.

Mr. Arthur Durham eulogised Mr. Pollock and the operation, and said that in a case of pigmentary nævus that had come under his care it was positively beautiful to see the islands of skin joining the mainland and the processes of repair proceeding so rapidly.

Mr. Callender quoted cases under the care of Mr. Pick and Mr. Willett, all of which had done well; and in reply to a question from Mr. Heath, said in all the cases cited, the ulcer was, as far as he knew, of the usual tertiary syphilitic form.

Mr. Pollock closed a long discussion by briefly explaining his own views as to the physiological aspect of the question, and as to the success of the operation in syphilis, and regretted that the state of Paris had prevented any recent intercommunication with Dr. Reverdin, the talented author of the operation. According to his own experience, and particularly with rupial sores, small pieces of skin answered as well as large; and, in this matter, some consideration should be shown to the patient.

DIALECTICAL SOCIETY.

Wednesday, Nov. 2.

Mr. F. Bourne in the Chair.

Dr. C. R. Drysdale read the following paper:—

ON THE MORTALITY OF NEWLY-BORN CHILDREN—AND BABY-FARMING IN FRANCE.

It has been remarked that France doubles its population very slowly, and that during the time that the British Islands doubled their population in fifty-two years, and Prussia in fifty-four, it would, at the present rate of increase, require 198 years for France to do this. Is this fact owing, in any great measure, to the death of infants? It would appear not. Of sixty-four children under one year of age, there died in France nineteen per cent. in 1865. In England about fourteen per cent. are *said* thus to die; but, then, all deaths under the age of five days are counted as still-born, and the registration in England is rather slovenly performed. Of 100 children born alive there die before one year, fifteen in Belgium, nineteen in Holland, twenty in Prussia, twenty-five in Austria, thirty in Bavaria. The cause of much of the mortality in France is traceable to faults in nursing. In Belgium and England suckling is held in legitimate honour. France has then not a high death-rate of its young infants, and hence we must look to other causes for the slow increase of its population. The main cause will be found to reside in the *small family system* prevalent in that country. "In many districts," says M. Maurice Block, "the peasants habitually limit their families to two children." There is, however, a great amount of mortality among the children of the Parisian population, and this is in a great measure to be accounted for by the extent of illegitimacy which prevails in Paris. The maiden mother has not the sanction of society; she, therefore, is liable to be in difficulties at the very time when she requires the assistance of all her friends to maintain her own existence, and that of her child. Thus, it has been found that still-births are much more common among the infants of unmarried mothers, than among those of married ones. In Austria, in 100 legitimate births there was, in 1865, one still-birth; in Sweden, Bavaria, and Norway, there were three; in Denmark, Prussia, France, and Belgium, four; in Holland, five; whilst, during the same period of 100 illegitimate births, there was three still-births in Austria and Bavaria; in Sweden, four; Denmark, five; in Prussia, Norway, and Belgium, six; in France, eight; in Holland, nine.

Bavaria alone of all these cited has an equality in the still-births of legitimate and illegitimate children, which is accounted for by the fact that marriage in Bavaria is made so difficult to contract that one-fourth of the births are illegitimate, and partners not married live with almost as much of the sanction of society as the rest who have passed through the state-marriage.

In France, against 928,934 legitimate children born in one year, 76,090 were illegitimate; in Bavaria, 134,289 were legitimate, and 39,389 illegitimate.

After the child of the unmarried woman is born, it stands at present, in most countries, a far worse chance of living than when the parents have the sanction of society granted to their paternity. The work-girl who desires to bring up her own child, may become nearly starved by so doing, and is apt to ruin herself irretrievably if she is known to nurse her own child. She thus often gives her child over to some baby-farmer, and in such a case it generally perishes.

According to French statistics, of 100 legitimate children, aged less than one year, sixteen died, and thirty-two per cent. of illegitimates; and generally, we may say, that wherever illegitimates most prevail, early infantile mortality is most common.

Many children in France are abandoned to the Foundling Hospitals, and these foundlings die in great numbers. Thus, from 1839-58, fifty-eight per cent. of these children in the Department of the Seine died. Even in 1864, thirty-nine per cent. of them died, although all were sent out of Paris to be nursed in the country. In the French provinces the mortality of foundling hospitals was very great. Thus, in Indre et Loire it was sixty-two; in Cote d'Oor, sixty-six; in Seine et Oise, sixty-nine; in Aubs, seventy; in Calvados, seventy-eight; in Loire Inferieure, ninety per cent. It surely was not much of an exaggeration to write above the door of one of these hospitals, "Here children are killed at the expense of the State." In the rural population of France there is one illegitimate to twenty-one legitimate births; in Paris, one illegitimate to hardly three legitimate births. In some parts of France the mortality of newly-born children is only from eleven to thirteen per cent. under one year, but in the departments about Paris it runs as high as from twenty-six to thirty-seven per cent. Paris loses no less than thirty-nine per cent. of all the children nursed in that city itself, chiefly owing to the large number of newly-born children, mostly illegitimate, who die in the lying-in hospitals.

A wet-nurse's nurture does not give a much greater mortality than if the child were suckled by the mother, on condition that the nurse live in the mother's house; but the sending of the infant into the country to nurse, as is done in Paris to such an extent, occasions very great mortality among infants. A kind of custom, however, has grown up in Paris, of thus exiling the infant from the maternal home until it is eighteen months old, and this custom seems to have existed for some centuries. In 1769 an office for wet-nurses was established in Paris under municipal supervision. Now-a-days the same office still exists, and is under the surveillance of what is called the Assistance Publique, a great agglomeration of all the charities of Paris under municipal government. The office is called the Bureau Saint Apolline, or Grand Bureau. It employs a certain staff of inspectors, directors, &c., to look after the nurses to whom the Parisian mothers confide their babies, and guarantees to the nurses a minimum of twelve francs a month, in case the mothers forget to pay the twenty-five francs a month they agree to do. Parisians seem, in many instances, to let the State pay for their babies, since, in 1864, of 1,416 parents who were debtors to this institution, only 618 paid what they owed, and 735 paid nothing, or only part of their debt.

This State office is by no means popular, either with nurses or Parisian parents, and only sends out about 2,000 babies a year. Parents think, justly enough, that it is an indignity to let the State manage their babies for them. The mortality of the children farmed out by this Grand Bureau is high, about twenty-eight per cent. for the legitimate infants, and thirty-three for the illegitimate. [From 1863 to 1866, 13,133 foundlings were also sent out, with somewhere about thirty-three per cent. mortality.] In 1821 some new offices called *petits bureaux*, were opened for nursing-out Parisian infants. The medical men attached to these are paid out of the income of the office, and hence are not so exacting on the nurses; hence nurses flock to these offices. No less than 9,136 babies were annually put out to nurse in the country by means of these little offices in 1864, and 2,500 Parisian nurses found places by means of the same offices. Besides these office-nurses, there are others with whom mothers in Paris treat directly, and these correspond with baby-farmers. The friends, relations, or compatriots of the servants at Paris, are often chosen as nurses by their mistresses. About three thousand infants are annually confided to these wet nurses. About 14,000 little Parisians are put out every year to nurse in the country districts by the great and little offices. The mortality among the children put out by the little bureaus is thought to be greater than that of the great office, and it is estimated that forty-eight per cent. of those nursed out without the interven-

tion of any office die, but there is nothing definite known as to this fact.

The evident chief cause of all this mortality is the custom of Parisian women of not suckling their own little ones. J. J. Rousseau inveighed bitterly against this absurd fashion, and, as it is *but a fashion*, we may hope that public opinion in Paris may soon put an end to it when this evil is once recognised. Very few women are incapacitated from fulfilling their maternal duties in this respect, far fewer than is supposed. On this side of the Channel we can hardly understand how such a fashion could have come into existence, but have only to remember the small feet of Chinese women, and small waists of a generation ago, and to understand.

Feeding-bottles, even, when rightly managed, are far less deadly than baby-farming, as practised in Paris, on the condition that good cow's milk alone be used, and maternal love exist, to stimulate to cleanliness of the utensils used.

Do what we will, I fear that a certain number of women will for many a year be forced to send their children out to nurse. Should the State or the municipality have the surveillance over such children? I fear that this would lead us into many evils. In Paris, the intervention of the State seems to suggest to Parisian parents a ready method of getting rid of the burden of parental duties, by merely *promising* to pay a monthly sum, about £1, to an office. This is most dangerous to infantile health, and productive of great mortality. Maternity societies, somewhat like the Society for the Prevention of Cruelty to Animals, are what is wanted, not any more bureaucracy. Such societies might aid poor mothers in quest of nurses, and prosecute any wicked baby-farmers. They might have correspondents in all our cities and villages; and thus, if no more children were born than would be a blessing to society, and to their poor mothers, we might only lose 12 per cent. of all infants, instead of 20·30 as now. One of the great causes of infantile mortality in France, England, and elsewhere is illegitimacy. In Paris, we have seen that more than one-fourth of the births are illegitimate; in Munich it seems that one-half are so; and the same occurs in Vienna. In Paris, and in Bavaria, there is an immense amount of unnecessary illegitimacy, and this is caused by the stringent regulations of the marriage laws of these countries. In France the consent of the relations is required to admit of marriage, and the law gives, I believe, no divorce in *any* Catholic country. Hence, marriages have much fallen off in many parts of the Continent, and notably in Paris, Stockholm, and Bavaria. It would seem to be an inference from this that we should expect to hear less of infantile mortality if marriage were rendered a less formidable contract than it now is in most countries. W. Von Humbolt thinks that the State should withdraw its care from contracts between the sexes, and leave these to individual choice. Mr. Mill says that no *legal* obstacle should exist to divorce, although moral ones may exist in insuperable degree. John Milton favoured easy divorce. In a conversation I had, in the spring of this year, 1870, with Dr. Lefort when in London, I stated what I believe, that in France, a country so prudent in the matter of offspring, the chief thing that is wanted is facility of divorce. This, I believe, would, in that country at any rate, lessen the death-rate arising from the shame produced by the loss of the sanction of society; and would also incidentally tend to do away with prostitution and its numerous concomitant evils. In England very much smaller families and more facile divorce are both needed.

Miss WALLINGTON felt compelled to declare in favour of State control of baby-farmers. In nine cases out of ten women were the sufferers by the thoughtlessness of men, and the emancipation of women was needed, in order to allow them to be able to make a living when they required this to nourish themselves and their infants. The education of women and their enfranchisement were much wanted.

Dr. EDMUNDS said that the idea of State surveillance of baby-farmers was a dangerous one. It was always the interest of a certain number of persons to cry out loudly for State interference; but the surveillance of nurses would increase, instead of diminishing, the amount of baby-farming in large cities. The registration of all women who took a baby to nurse might, however, be made compulsory without much difficulty. In workhouses, the chief cases of women who came to be confined in the wards were domestic servants. These girls were confined in large wards in company with some most abandoned women, and when they left they were obliged to take their children with them. Being very poor, the children died in great numbers. Nurse children are also sent to the workhouse; and a large number of children, whose mothers die of consumption, are brought up in wards, where they pine away and suffer greatly from the want of breast-milk. The guardians always refused to let a woman leave her infant in the house, or to take in a nurse-baby if they could help it.

Mr. NUNN said that one cause of the mortality of children was that more were born than need be, and it was a flagrant injustice that a married woman had not, like a single one, the right to her own person, by the law of England. It was also a shame that single women should be so severely treated when they obeyed the imperious command of nature in reproducing themselves.

Mr. R. J. DRYSDALE said that he was, in the present state of society, greatly in favour of State aid and foundling hospitals. Some few years ago he had visited Moscow, and seen a splendid Foundling Hospital, where 600 children were farmed out, and where the children looked well and hearty. State supervision was wanted, and, doubtless, the French State supervision was bad, or the statistics given by Dr. Drysdale would not be so bad.

Dr. C. DRYSDALE asked whether Mr. Drysdale knew what the statistics of the Moscow Hospital were. He believed they were bad, and the mortality very high.

Dr. EDMUNDS said that Mr. Malthus had visited the hospital in 1798, and remarked, that with all the care, the mortality was very high, and, doubtless, the present condition was no better. Children did not get on without breast milk and a mother's care.

Colonel CLINTON thought that some sort of inspection of baby-farmers should exist.

Mr. WILSON said that the inhabitants of this country, in their hearts, were at a loss what to do with the number of children born, and would, he believed, be glad enough if the children in the workhouse would not live. The fact was, the country was over-peopled. The French peasants were anxious to restrain their families in order to secure to them the same amount of land as they themselves found. It was a cruel thing to bring so many infants into life to suffer and die.

Mr. RUSSELL said that in England and Russia the population had doubled in fifty-two years. In the United States of America it had doubled, quite independent of any immigration, in twenty-five years, on several occasions. Our mortality was decreasing in this country, so that our power of doubling was becoming greater, and we should have to suffer much from poverty if we yielded to it. There was chronic over-population in this country, and it was better to look it fair in the face and resolve not to breed so fast. In this case, we should not require laws against baby-farmers. This was the root of the question.

Mr. RIGBY SMITH said the enormous difference in the death-rates of the countries, such as England and Italy, &c., showed the danger of rapid multiplication of families, which always caused great infantile mortality and preventible disease.

Dr. WYLD was of opinion that the views of Malthus were easily shown to be historically fallacious. Moreover, he held that the collapse of France could be shown to be owing to the domestic habits of having only one or two children.

Dr. DRYSDALE asked Dr. Wyld how he was sure of this, as several causes had been assigned for the unfortunate position of the French?

Dr. WYLD said the habits of the French led them into all kinds of deceit, and ruined the character of the nation, whose word could no longer be depended on.

Dr. THOMPSON DICKSON, in reply, said that, although Dr. Drysdale said that State supervision had failed in France, it did not follow that it would fail here. Lunatics were now under State supervision, and infants, being helpless, should also be watched over by the State. A perfect registration would do good. He had just come from a trip to Scotland, and whilst there had applied to the Registrar-General for facts. Dr. Stark had informed him that infanticide and baby-farming were almost unknown in Scotland. Illegitimacy is very prevalent in Scotland—9·7 per cent. of births are illegitimate. Thus, Scotland was one of the most unchaste countries in Europe; but all children of a woman are made legitimate when she marries in Scotland, and marriage is an exceedingly simple affair in Scotland. Consent between the parties is sufficient. Divorce, however, is difficult. At a pic-nic, two young people, friends of his, at Gretna Green, proposed to get married in a frolic by the blacksmith, who performed the ceremony for sixpence. It took them four years to get a divorce. Dr. Dickson, in conclusion, said he had not given attention to the ques-

tion of over-population; but he held that there was not much to be apprehended on that score. Divorce should be made much more facile than at present; and he held that partners who hated each other should be allowed to get free.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XIV.

PRECIPITATION OF SEWAGE WITH CAUSTIC LIME.

AT Hertford the sewage works are managed by the New River Company, who are compelled by their Act of Parliament to deodorise and purify the sewage of the town before it is discharged into the River Lea, and this they accomplish by means of lime. The town has a population of about 7,000 persons, and being well sewered, the whole of the sewage, together with a large volume of subsoil water, is subjected to treatment at the works. The flow of sewage amounts to about 1,640,000 gallons a day, which is as much as 234 gallons per head of the population, or nearly ten times as much as the water supply. The distribution of the flow during the twenty-four hours is at the rate of 70,000 gallons per hour in the day time, and 66,000 gallons in the night. It runs by gravitation to the works, which are a little beyond the town, and is delivered into a subsiding tank 140 feet long and 20 feet wide, where it receives a dose of lime in a creamy condition, the lime being delivered by means of little buckets attached to a water-wheel which is turned by the effluent sewage, and in this way the quantity of lime is exactly apportioned to the rate of the flow of sewage. The subsiding tank is divided by two cross walls a little under the water line, and thus the sediment is kept back, while the supernatant water passes on to be discharged over a weir into a filter bed about twenty feet square, composed of six or seven inches of coarse gravel at the bottom, and three inches of fine sand above, and thence it passes into the effluent channel which is about a mile long, and so onwards into the River Lea at Ware Mill. The quantity of lime which was used at the time of our visit to the works in October, 1866, was about eight and a-quarter bushels per day, and to this were added 150 lbs. of chloride of lime, making a proportion of nearly two grains of lime and 0·64 of a grain of chloride of lime per gallon of sewage. The time or duration of the flow of sewage through the subsiding tank was about forty minutes, which is much too short for complete subsidence. The tanks and filters are in duplicate, and the former are worked for three days, when the precipitate is removed, and the latter are cleaned out daily. The sludge or precipitate is placed upon a covered platform between the tanks, where it drains and consolidates; and after a period of three or four months it is sold to farmers at the price of 2s. 6d. per load. In this manner about 12 cwt. of solid matters are removed from the sewage daily. The effluent water is a little turbid when it leaves the filters, but it soon becomes clear, so that after flowing along the out-fall channel for about a quarter of a mile, it becomes quite clear, and fish and aquatic plants are found in it in abundance. The composition of the sewage and the effluent water on three occasions in 1866 were as follows:—

Constituents per gallon.	December 13. Raw sewage.	December 13. Effluent water.	August 31. Raw sewage.	August 31. Effluent water.	August 26. Raw sewage.	August 26. Effluent water.
	Grains.	Grains.	Grains.	Grains.	Grains.	Grains.
Soluble matters	30·33	27·00	29·30	27·25	26·95	26·00
Organic	5·35	2·51	1·95	1·20	1·70	1·00
Mineral	24·98	24·49	27·35	26·05	25·25	25·00
Suspended matters	5·39	0·74	6·30	1·30	2·05	0·85
Organic	0·71	0·24	3·25	0·60	1·05	0·35
Mineral	4·68	0·50	3·10	0·70	1·00	0·50
Total	35·72	27·74	35·60	28·55	29·00	26·85

When we visited the works in November, 1867, the quantity of lime was fourteen bushels a day, with one bushel of chloride of lime. This was in the proportion of 3·43 grains of lime and 0·33 of a grain of chloride of lime per gallon of sewage; and the composition of the sewage and effluent water were as follows:—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Matters in solution	25·00	28·33
Organic matter	2·50	1·25
Ammonia	0·343	0·457
Ditto organic	0·480	0·560
Nitrogen as nitrate	0·026	0·091
Oxygen required to oxydise	0·296	0·281
Matters in suspension	1·42	0·43
Organic matter	0·72	0·17
Mineral ditto	0·70	0·26

From which it was evident that nearly all the suspended matter, and about half of the dissolved organic matter, had been removed from the raw sewage by about three

and a half grains of lime; and the chloride of lime, although amounting to only one third of a grain per gallon, had completely disinfected the sewage, and had also prevented the growth of the sewer fungus in the effluent channel, so that the water when it reached the river Lea was sufficiently pure to be admitted into it. In fact, the results of these and the Leicester works were so satisfactory in 1867 to Dr. Frankland, Dr. Letheby, and Dr. Odling, who visited them at the time in question, for the purpose of advising the conservators of the river Thames on the subject of the defæcation of sewage in the Thames Valley, that they reported of the process as follows:—"By this process the sewage was deprived of its suspended, and of a considerable portion of its dissolved, matter. But, as in the last case (irrigation), it was necessary that the defæcated sewage should be received into a considerable volume of running water to prevent secondary putrefactive change. At Hertford, the defæcated sewage water is filtered through coarse sand, and runs a distance of nearly a mile before it enters the river Lea. We remarked that, although it left the filter a little turbid from suspended lime, yet it became clear after it had run about a quarter of a mile in the conduit. In the performance of this process of defæcation, we are of opinion, from the results obtained at Leicester and Hertford, that—1st. The proportion of lime should not be less than one ton, and that there should also be used fifty-six pounds of chloride of lime per 1,000,000 gallons of sewage; 2nd. That the mixture of the sewage with the lime and chloride of lime should be very complete, and that the mixture should be agitated so as to aggregate the suspended matters, and thus assist in the subsequent precipitation of suspended matters; 3rd. That the sewage when thus treated with lime should flow along two subsidiary tanks in series—the first should be capable of holding at least an hour's flow of sewage, and the second of holding not less than four hours' flow. The tanks should be four feet in depth, and the overflow of the defæcated sewage should be by a weir only half an inch below the surface; 4th. That there should be a double set of tanks for alternate working; 5th. That the defæcated water should flow through a shallow, open conduit if not less than a quarter of a mile in length, before being received into a stream of freely running water, if not less than eight or ten times the volnme of the defæcated sewage."

The conditions recommended by Dr. Letheby to the referees appointed by the Metropolitan Board of Works in the year 1857 to enquire into the subject of the main drainage of the Metropolis were as follows:—

1. The lime should be used in a perfectly caustic state, and in the proportion if not less than twelve grains per gallon of sewage.
2. It should be well slaked with water, and got into a finely-divided or creamy state.
3. It should be thoroughly mixed with the sewage, and well agitated before it is set aside to deposit.
4. The precipitate should be allowed to settle with the liquid quiet for at least one hour.
5. The deposit should be consolidated and deprived of its water as speedily as possible.

And he further advised that, in summer time, the subsiding tanks should not be worked for more than two days without removing the deposit, as in warm weather this was apt to putrefy, and rise in large flakes, thereby promoting the decomposition of the supernatant water, and rendering it turbid.

Wherever these conditions have been observed, and the process has been carefully conducted, the results have been satisfactory, and no nuisance has been created; but, on the contrary, when the working of the process has been neglected, as at Tottenham since Mr. Higgs's time; at Leicester on many occasions, and notably of late; at Cheltenham; at Blackburn; and at Leamington before the A. B. C. process was adopted, the defæcation of the sewage has been very imperfect, and complaints have been justly raised against the nuisance occasioned by the neglect of those who have had the care of the work.

In concluding this part of the subject we may refer to the observations of Dr. Hoffmann and Mr. Witt in their "report of chemical investigations relating to the Metropolitan Main Drainage Question," wherein they state that "the treatment of sewage with lime appears to be one of the most promising of the many processes for obtaining from sewage a deposit which, when dry, may be employed as manure;" and they give the following as the result of their experiment on 40 gallons of London sewage with 800 grains of lime (that is, with 20 grains of lime per gallon of sewage):—

Constituents per gallon.	Raw Sewage.	Effluent water.
	Grains.	Grains.
Matters in solution . . .	107·60	96·02
Organic matter . . .	52·36	40·34
Mineral ditto . . .	55·24	55·68
Matters in suspension . .	52·49	
Organic matter . . .	36·40	Traces.
Mineral ditto . . .	16·09	

So that, with 20 grains of lime, the whole of the suspended matters were removed from the sewage, and rather more than a fourth part of the dissolved organic matter; in fact, the total quantity of organic matter removed amounted to 54·55 per cent. of all that was present in the original sewage. With 12 grains of lime at Tottenham, we found the proportion to be 35 per cent., and at Leicester, 58 per cent.; whereas, according to Mr. Versmann, the average amount of organic matter removed from the sewage at Leicester, in the ordinary way of working is 38 per cent.

Constituents per cent.	Tottenham. (Higgs.)	Leicester. (Voelcker.)	Leicester. (Versmann.)	London. (Hofmann and Witt.)	Clifton Union. (Hofmann.)
Moisture . . .	5·25	10·52	4·06	0·00	0·00
Organic Matter . . .	31·60	12·46	26·32	43·95	20·12
Phosphate of lime . .	8·64	2·27	2·32	6·35	3·08
Mineral matter . . .	54·51	74·75	67·30	49·70	76·80
Total	100·00	100 00	100·00	100·00	100 00
Nitrogen	—	0·60	0·56	1·55	0·62
= Ammonia . . .	—	0·72	0·68	1·88	0·75
Money value per ton of dry substance . . .	s. d. 29 6	s. d. 15 5	s. d. 17 0	s. d. 38 9	s. d. 16 9

The composition and money value of the dry deposit from the sewage of different places, as determined by different investigators, will be found in the preceding table.

These values are calculated at the rate of £56 per ton for ammonia, £7 a ton for insoluble phosphate of lime, and £1 a ton for organic matter; and it is assumed that the Tottenham deposit contained 0·82 per cent. nitrogen, which is equal to 1 per cent. ammonia.

ANOTHER MEDICAL BILL.

We mentioned some time ago that the *Lancet* had promised to produce a Medical Bill. We have now to report that our contemporary has, at length, published its proposal and invites criticism upon it. Our own interest in the subject of Medical Reform has been proved by the many articles devoted to it of late years, and we shall, naturally, be expected to say something of our contemporary's measure. We appeal confidently to our past to prove that we approach the subject with every desire to do justice to all. As our contemporary observes, by way of prefix to a summary of the Bill, "It is an easy thing to complain of the work of others; It is a much more difficult thing to do better." This we freely grant, and are prepared to make every allowance for. Still, a measure put forward in the complete form of a Bill, announced weeks before hand, and explained in a leading article of nearly two pages, which closes with a cordial invitation to all interested to offer their criticisms, does, undoubtedly, challenge the fullest discussion, and we have, accordingly, most carefully perused every clause before sitting down to write about it as a whole. What we are about to say we may indeed hereafter modify or supplement, but we are sure that the proposers of the scheme will not deny that we have endeavoured to do it justice.

The first point is, that a radical reform is to be effected in the constitution of the General Medical Council. This, of course, was a foregone conclusion. In common with every medical reformer, the *Lancet* has over and over again expressed dissatisfaction with the composition of that body. What is proposed then? A new Council of twelve persons, of whom four are to be nominated by the Crown, four by the medical authorities, and four are to be elected by the registered practitioners.

The primary defence of this scheme is the assertion that the existing council is too large. This is a statement that has been constantly repeated in various quarters, and is accordingly put forward as if it were axiomatic. Our readers, however, are well aware that we have not committed ourselves to this view, nor do we even now feel convinced. The only plausible objection to a large council is the expense of it, and Dr. Andrew Wood has more than once shown how that can be obviated. It is undeniable that the various opinions of so large a body as the Medical Profession could not find expression in so small a number of individuals as twelve, and we, therefore, hesitate to demand a smaller Council than we have. This hesitation becomes more decided when we turn to the proposed composition of the new Council. Two members are to be elected by the registered practitioners of England, and one by those of Ireland and Scotland respectively. The four nominees of the Crown are to be divided between the three Kingdoms in the same proportions. Lastly, the Corporations and the Universities located in the three Kingdoms are respectfully to combine or amalgamate, to elect in England two representatives, and in Scotland and Ireland one each. Now, on the face of it, this is a sort of hotch-potch after all. The new Council is constructed on no principle. It evidently aims only at adding the representation of the registered practitioners to the existing elements. We should have preferred a bolder course. It may easily be argued that the Council should represent either the Profession or the public. The medical authorities were given representation because it was thought they represented the former, and also, to some extent, the latter. Their intense sense of corporate existence has frustrated the intentions of the Legislature, and rendered a change necessary. But medical men totally unassociated with any University or Corporation do not at present exist in this country. A proposal by *Mr. Charles Hawkins*, a member of the Council, for a Council of twelve, from which the representatives of the medical authorities are excluded, seems to us at least more logical. A controlling body, it may fairly be urged, should be independent of those whom it is to control.

There is another point that is sure to be raised, and which, therefore, we may as well allude to—the proportions of representatives assigned to the three kingdoms. The numbers of the practitioners resident in England are not exactly as two to one of those in Ireland or Scotland. Let that pass, however. Why should the Crown Nominees be nominated for the separate nationalities. We are assured that these Crown Nominees will represent the public, but the public interests in England, Ireland, and Scotland, are precisely the same. What should be the qualification of each? Would an Englishman resident in Dublin be a fit nominee for Ireland? Or, would an Irishman resident in London with English diplomas be eligible? Again, the corporations will not, we may be sure, be ready to admit that their claims could be amalgamated in such a way. The Irish authorities are as numerous as the English, and in every way their equals, but are only to have half the representation, and the Scotch, we may be sure, will cry out passionately against being thus eclipsed.

There is one point, too, we should have expected to be more fully elucidated. By whom are the representatives of the several bodies to be elected? The *Lancet* has stated

several times that the College of Surgeons consists of the Fellows *and* Members. Would it not be well to have this expressed in the Bill, and the same rule applied to other bodies ?

The next feature of the Bill is the election by the reformed Council of a National Examining Board for each of the three Kingdoms. So far as letting the Board be elected by the Council, we have always advocated this. But why three Boards ? It is hardly worthy of our contemporary's position to bid for popularity by this yielding to the prejudices of a few. One Board would be enough, and we yet hope the cry for a single one will set aside this territorial distinction between the three divisions of the United Kingdom. The *Lancet's* support of the one portal system seems to falter when it proposes three. The very terms in which this is conveyed show this. We are told, "The one portal entrance to the Profession will be through one of these boards," which, to say the least, sounds funny.

That the Board may be effective, it is ordered that "the Council shall appoint only such persons as Examiners as are of approved skill in the several subjects on which they have to examine." The Council would scarcely do otherwise, although *legally* the qualification is not well defined. It might almost, we should think, be left entirely to the discretion of the Council. A further guarantee is, however, proposed,—viz., the appointment of Inspectors of Examinations ; whether such *paid* officials should be necessary is a question on which differences of opinion are likely to arise, but the proposal is worth considering, and shows earnestness in the attempt to devise a scheme of thorough reform.

Last year, it will be remembered, some bodies demanded the right to give their diplomas to those who had not passed the National Boards. It is a pleasure to observe that our contemporary has gradually been coming to the conclusion that we have always maintained—that no other diploma should be given until after the State Licence had been obtained. A little concession that we may freely grant if it assist in disarming opposition is offered in the scheme before us. Permission is to be given to candidates to be examined by any of the medical authorities, but the degrees or diplomas are not to be actually conferred until the National Licence has been obtained. This is certainly an advance, and we hope no further concession will be expected.

Another good point in the Bill is, the attempt to neutralise the evil of three Boards by giving the licence in the name of the General Council. Still, there would be the old territorial bugbear, "I passed in England—he passed in Scotland," &c. One Board would prevent all this as well as other inconveniences.

There are many other less important points which may be passed over at this stage of the discussion. We freely admit there is value in the Bill, although we have not hesitated to respond to our contemporary's "challenge," by freely criticising its leading provisions. This, we trust, we have done in a spirit to which no one can take exception. We have only one remark to make in conclusion ; the *Lancet* is assuming more than is due in claiming the Bill as its own creation. Our contemporary should, at least, be prepared to do justice to other reformers—not to one or two, but to all. In the leading article explaining the Bill—almost every feature of which, to our readers, must be old—not new—we read these words, "We have not hesitated to appropriate all that was good in the Bill of the Government, and for one important clause, we are indebted to the Bill of the British Medical Association. With these qualifications the Bill is essentially our own." Now, here in the name of common honesty, we are bound to protest. Few of the provisions are really new. Most of them have been discussed in our columns by various persons, and some have been advocated by various able and energetic reformers for several years. That the Council should appoint and control the National Examining Board was proposed by Dr. Prosser James before the Act of 1858 was passed. The same reformer has from that time to this, strongly maintained that no other diplomas should be granted until the State Licence has been obtained, and the *Lancet*, we are happy to say, virtually at last endorses this view. Even paid Inspectors have often before been talked about, and are, in fact, but a substitute for the system of visitation that has been organised by the existing Council. A small Council is no new idea. Only lately the magic number of twelve has been once more advocated by an experienced member of the Council, Mr. Charles Hawkins. What then remains ? In truth, very little. That a journal may fairly claim credit for marshalling the ideas of others, we are ready to admit ; but to confess obligations on the one hand and repudiate heavier ones on the other, is a course we are compelled to condemn. No doubt, reformers of all parties may be glad to have their views supported by the *Lancet*, but to appropriate ideas and coolly say the scheme including them "*is essentially our own*," is so contrary to all notions of respectable journalism, that we can only suppose that, by some fatal blunder, the printer must have omitted a phrase from the sentence, *Palmam qui meruit ferat*. Our contemporary must really expect no credit for originality in the framing of this Bill, for every feature seems to have been suggested by other reformers.

Notes on Current Topics.

Prevention of Scarlet Fever.

A GREAT deal of talk is going on just now about the prevention of scarlatina. Dr. George Johnson is one of the most zealous in this good cause. A sufferer from scarlet fever, he says, is for about a month throwing off poison, chiefly contained in the discharges from the throat and nostrils, and in the flakes of epidermis. Therefore, the patient should be isolated, in a top room of the house if possible, and should spit into a basin containing Condy's fluid. Also any rags with which the mouth and nostrils are wiped should be burnt. The urine and fæces should be passed into utensils containing Condy's fluid. The patient's bed and body-linen should be immersed in boiling water on removal, and then in carbolic acid ; and not washed in company with any other linen. A warm bath should be given to the patient occasionally. When the slops are put into closets carbolic acid should be poured down immediately afterwards. Papers, in rooms where scarlet fever has been, should be removed, and the room whitewashed, &c. Mortuary houses should be provided for the poor. Well ! all of this is quite clear and easily understood, and yet we don't think that scarlatina can ever be much prevented. The disease is so contagious,

that, except in the case of rich people, it cannot be kept from spreading wherever children are crowded together in houses, schools, or hospitals. N.B. Children's hospitals are on this very account a mistake. In short, much as we approve of Dr. Johnson's views, we can't help believing that, until some Jenner appear to give us a milder disease instead of it, scarlatina will have its victims in about an equal quantity yearly in spite of such precautions, or, at any rate, some other contagion will carry off poor people so long as poverty is common.

Medicine and War.

What do Medical men in general think of war? It would be presumptuous, of course, to decide as to what the opinion of each individual of such a large body of men might be on such an important question; but our own experience has led us to think that there is no class in the whole of modern society who so much and so justly detest everything connected with war as the Medical Profession in all countries. In the first place, everyone knows that Medical men are not so much accustomed to receive empty honours as the members of other professions. Scarcely any among us have ever even dared to aspire to becoming Members of Parliament; and the number of us who have been raised to the doubtful dignity of titles is but small indeed, in comparison with the hosts of knights, baronets, and peers that have been created from the legal profession. Not being much accustomed, then, to hope for public recognition of our important functions, we have resigned ourselves patiently to our fate, and been accustomed to work for the sake of being simply useful to our fellow-citizens, and for the sake of the real advancement of human happiness. Such being the case, it cannot be expected that Medical men can do otherwise than sternly condemn war in the abstract. Although the commonplace citizen, whose experience never leads him among scenes of human agony and disease, may be able to think complacently about the glory his country is to achieve from making war upon some powerful nation, and although the aristocratic portion of our society may eagerly long to exchange the vacuous existence of modern fine gentlemen for the more stirring and active life of the army, the members of the Medical Profession are not likely to be led astray by any such drivelling about "honour" as will easily mislead the vulgar herd, remembering, as we are bound to do, the host of pale-faced martyrs which Bellona ever drags in her train.

These ideas have been brought to our mind by the suggestion that we, the peaceful inhabitants of these islands, are not at all unlikely to be dragged into these throat-cutting occupations. Having a vivid recollection of the horrors of the siege of Sebastopol, and the cholera and typhus fever and frost-bites in the trenches, we cannot but pray that our beloved country may be spared another such trial.

Medical Men in Public Positions.

It has often struck us, that civilisation will never advance much until the ideas suggested by the study of medicine become more extensively represented in European National Councils. The majority of lawyers, traders, and clergymen are utterly unfit to give an opinion on numberless questions, which are clear enough to the averagely-educated practitioner of the healing-art. Both the Church and the Bar are far too ideal in their philosophy in general, and not nearly enough accustomed to consider man as an animal, subject to the same wants as the rest of the fauna of the globe. The consequence of which is that, in our periodical literature and in our daily papers, so much contributed to by barristers, there is an amount of sentimentalism and want of appreciation of the sorrows of human life which is quite heart-rending, and which leads to the most disastrous results. Much as we respect the modesty of the members of the noble profession of medicine, we are disposed, then, to urge upon them the necessity of taking a greater part in public affairs than has hitherto been their wont, convinced as we are that, by so doing, society at large has everything to gain. Those among us who are rich enough ought to endeavour to become Members of Parliament; others, whose time permits, should strive to become members of Town Councils or School Boards; and those who cannot give time for such engrossing employments ought occasionally to deliver popular lectures on science, in order, if possible, to remove a little of the crass ignorance which leaves the public in general so easy a prey to unscrupulous politicians and anonymous journalists. There are many of the latter whose interests in such a matter are what Bentham well designated, sinister; and there are no persons so able to expose such artifices as are wont to be made use of by these dangerous classes as the enlightened members of the Medical Profession, whose whole lives are spent in a warfare against disease, poverty, and misery.

Medical Candidates for School Boards in London.

Professor Huxley, in speaking lately on the subject of school boards, said, "he believed that those gentlemen who were endeavouring to get on the board for the purpose of promulgating sectarian principles would, if elected, find themselves bitterly disappointed, because Mr. Forster had reserved to himself a despotic power to clip their wings.' There are many well known to be thoroughly enlightened friends of non-sectarian education. Let us hope that all such may be returned for the Board, and that our Profession will have some representation in public affairs. Education, physiology and hygiene want representatives more than any other body of doctrines.

Baby Farming.

The St. Pancras Guardians have had an important case to investigate. A woman, who was nursing a child, and who no longer received sufficient funds from the parents, attempted to hand over the child to the care of the workhouse, as it is related that the unfortunate woman, Mrs. Waters, did. It appeared that the parents had absconded. The Board of Guardians resolved to refuse to take the child, and determined to refer the case to a police magistrate. We don't understand the grounds of their refusal; it tends towards causing infanticide.

Dr. Lankester on Vaccination.

This able coroner, in a recent inquest made at Islington, on the body of an infant of five months, who had died of small-pox, being unvaccinated, remarked that the vestries have the power to send people neglecting vaccination laws before a magistrate, who had the power to fine them. The great mass of the people were on the side of vaccination

In Ireland, where vaccination is still carried on, the disease is almost unknown; and this might take place in England. The jury returned a verdict of death from small-pox, and censured the mother for her culpable neglect in not having the child vaccinated. Anti-vaccination is an ugly superstition.

Skin-Grafting.

Mr. Dobson, at a recent Medical meeting, mentioned cases in which he had treated ulcers by transplantation of skin. He takes small pieces of skin from the upper arm not larger than split peas, divides them on his thumb nail into five, seven, or twelve pieces, and grafts them into the granulation, in incisions made by a sharp lancet by means of the point of a sewing needle. In a granulating surface, after loss of the entire integument of the leg from phlegmonous erysipelas, he had made twelve transplantations of skin not larger than a pin's head, eleven of which were growing vigorously. The average growth of the cicatrix was about the size of a sixpence from each point. Mr. Pollock exhibited to the Clinical Society several cases of the operation devised by M. Riverdin, of Paris, in 1869. A girl, aged eight, had been in St. George's Hospital with an ulcerated surface from buttock to knee, which had existed for two years. Mr. Pollock first transplanted two small pieces of skin, about the size of millet seeds, taken from the lower part of the abdomen. Fourteen pieces in all were transplanted at various periods. The burn was nearly healed in five months, without any perceptible contraction of the cicatrix. Mr. Pollock transplanted usually very small pieces, and takes care that the granulations are healthy where he inserts them. Mr. Lawson showed a patient in whom a large ulcer in the leg had resisted all treatment for four years, and was completely cured in four weeks after a piece of skin, the size of a fourpenny-piece, had been planted on it. As soon as the new skin had established its vitality, granulations sprang from the circumference, and rapidly closed in the wound. The granulations should be healthy, no fat transplanted, but only skin, which must be accurately applied to the granulating surface. The new skin is kept in position without interruption and lightly covered with a layer of lint, over which is a small compress of cotton wool and a bandage, for the purpose of keeping it warm until it grows on to the part.

The Working of the Contagious Diseases Act.

The *Saturday Review* replies to the arguments and statistics put forward by Mr. Duncan M'Laren, M.P., in favour of the repeal of the Contagious Diseases Act in the following terms:—

We will now state his arguments, and the answer to them, as shortly as possible. First, as to the amount of prostitution. Mr. M'Laren is extremely indignant with the assertion that, whereas in the five years during which the Acts have been in operation 7,766 women were placed upon the register at the various stations affected, there are now only 3,016. The bearing of this fact, which he does not deny, has, he says, been grossly misrepresented. People have assumed that 7,766 women were on the register at one time; whereas that number represented only the total of those who have been placed upon it during five years. If anybody ever assumed that there were 7,766 women on the register at once he was undoubtedly wrong. But it is not stated in the Parliamentary returns; nor was it stated in Dr. Lyon Playfair's speech in the recent debates; nor have we ever seen the statement officially put forward. The number presents all the women who were at any time on the register; and the important fact which the figures were adduced to show is, that of that number twenty-seven per cent. have been restored to respectable life, either by marriage, by entering homes, or by returning to their friends. The facts, he says, "are these: In place of 1,770" (we will explain this number directly) "there were only 203 of these women at Devonport when the Act came into operation in 1865; and in place of the steady and increasing diminution alleged to have taken place, the number has largely increased"; and Mr. M'Laren goes on to say that it is now 645. Now the simple fact is, that owing to the deficiency of hospital accommodation and other circumstances, the police began by placing only a small fraction of the whole number of women upon the register. Therefore the whole number on the register gives no sort of information as to the whole number in the town, and Mr. M'Laren has—unintentionally, of course—entirely misinterpreted the figures. But if he had wished to know what the numbers really were, he need only have looked at the returns presented to the House of Commons on the 8th of last August, and he would have discovered on page eight that the whole number of women in Devonport was, 1,770 on December 31, 1865, and on the same day in the four following years was 1,238, 1,010, 820, and 662 respectively.

We now take his statement as to the amount of disease. He takes the case of Chatham, and says that, whereas the number of residents in the district was about constant, the number of women sent to hospital had increased in four years from 277 to 697. This is quite true, but he quietly omits to state that, whereas in 1866 the number of medical examinations was 439, the number of examinations in 1869 was 4,414. If we argued from these facts alone, it would appear that the proportion of disease found in the first year was sixty-three and in the last fourteen per cent. This, however, would be unfair, because in the earlier years, when accommodation was defective and the Acts not brought fully into operation, the officials employed selected those cases only in which there was the greatest probability of disease. The returns do not justify us therefore in speaking positively upon this point. We will consequently take the case of Devonport, of which Mr. M'Laren has made so much; and we take the figures given by Mr. Bulteel, the surgeon to the Royal Albert Hospital, to which all the cases are sent. Now we find that, whereas in the quarter ending March 31, 1868, eighty-eight per cent. of the women examined were infected, the numbers diminished steadily and rapidly in every subsequent quarter, the percentages for the last six quarters, down to June 30, 1870, being twenty-two, twenty-one, fifteen, eleven, twelve, seven. It is impossible to imagine more conclusive testimony; and we will add that the number of prostitutes in the district diminished in the same period from 1,020 to 620, the number of brothels from 224 to 120, and the number of men infected which had previously been much greater from twenty-one to thirteen per thousand.

Demonstration against Female Medical Students in Edinboro'.

We record with a feeling of deep humiliation the occurrence of a very disgraceful riot, in the form of a demonstration on the part of the male against the female students, in Edinboro'. Shortly before the afternoon class, at the Royal College of Surgeons, for the demonstration of anatomy assembled, about 200 young men, congregated within the College railings, and commenced to shout, hoot, and yell in the most unseemly manner. When the lady students appeared at the College, the gates were shut in their faces by the rioters within, and it was some time

before they could gain admittance to the demonstration hall. Dr. Handyside's mixed class having at length assembled, the male students immediately took steps to prevent the lecturer from being heard by singing songs, beating all the while a deafening accompaniment with their feet. In the meantime, the students outside continued their uproarious proceedings. Having procured a sheep, they perpetrated a weak practical joke by thrusting the animal into the room where the anatomical class had met. After the breaking-up of the class, the lady students delayed for a time their departure from the hall. Their appearance was the signal for a renewed outbreak of hooting, hissing, and yelling, which was continued in the most outrageous manner as the rioters accompanied the ladies along the street. The police at last interfered, and apprehended four of the ringleaders.

We cannot expect much calm reason or cool judgment from obstreporus medical students; but they ought, nevertheless, to see that, as actors in such a scene, they are guilty of the very same fault for which they hoot and insult their female co-students. They take this way of punishing women for forgetting the characteristic modesty of *their* sex, while they themselves forget the manhood and respect for weakness which ought to be the boast of theirs. No course which the most ardent disciple of woman-doctoring could pursue would be half so powerful in overcoming objections as the most injudicious and ungentlemanly course adopted by the students.

If they make martyrs of the female students, we shall ourselves almost be driven to argue in their favour. The proper method of manifesting their disgust of unwomanly and immodest tendencies would be to shun contact or speech with female students as unworthy to be treated with the consideration and gallantry due to modest ladies.

Boards of Guardians.

THERE are certain so-called "Guardians of the Poor," whose education and pursuits give them an indisputable claim to the free exercise of their bigoted and narrow-minded views; and whose souls are scarcely able to soar above the counter, or beyond the limited acreage of the field of which they may boast possession—and we feel a tinge of shame mount to our cheeks to write it—these are the men, before whom some of the less favoured of our profession are compelled to bow; and what is worse to find themselves suddenly hauled up before an august assemblage of mercenary beings, and subjected to the cumulative process of insult and abuse over some imaginary grievance, or for the over-scrupulous discharge of his duties to the poor; and an unimpeachable reputation sullied, perhaps, for life. The Worcester Board of Guardians has lately made a public bid for this distinction. The victim, in this instance was Dr. Woodward, one of the Poor-law Medical Officers, whose salary we find on reference to the *Directory*, is £100 per annum for a very large district, or the magnificent sum of *one shilling and a half-penny for each case*, this sum, including, besides medicines as a rule, an average attendance of six weeks. The offence he was charged with, was the recommending two union (out of some two thousand) cases to the Dispensary, and this *crime* was actually six hours—six minutes would have been more than enough—under investigation. Happily, however, the mass of intelligence understood by the word "board" to which we refer, and we have pleasure in chronicling the fact, was not entirely homogeneous, for amongst them were found men who did not shrink from their duty, but manfully defended and vindicated the character aspersed.

Space forbids us going fully into this investigation, but the voting showed plainly the estimation in which Dr. Woodward is held by the intelligent portion of the guardians; and the verdict agrees with our views upon the subject, as from the evidence before us we fail to see the slightest fault on Dr. Woodward's part. It transpired that both cases brought forward were seen the same day the orders were given (which was also the case in another totally unfounded charge reported in the following week). Neither of the patients themselves appear to have had the slightest complaint to make, and as an earnest of Dr. Woodward's attendance on his other patients, we see that he was up two successive nights, and engaged nearly the whole of the intervening day with two Union cases only a few days before.

One thing is certain, that, however much hot water Mr. Williamson may have swallowed (according to a retort of Mr. Bozward), some of the guardians are not wanting in the quantity of cold water they are ready to throw upon their doctor. We think Dr. Woodward has been unjustly and undeservedly attacked.

Cork District Lunatic Asylum.

Mr. DUNSCOMBE commented on the new rules for the government of Lunatic Asylums, and stating, that they had almost removed the last semblance of authority from the governors. Everything was now centralised at head quarters, the local administrative body—or what was supposed to be such, of each asylum, being obliged to do things on the mere order of the Government. The rules took from them all proper title to the names of governors, and made them merely a society for registering the edicts of their masters, leaving in their hands only an unlimited power of taxation (hear, hear).

Mr. Clery, moved that advertisements be issued for the election of an Assistant Resident Medical Superintendent in the Asylum.

Mr. Perrier said he believed such an officer was not at all necessary. Nevertheless he should second the motion for the simple reason, that the Government would send down some person whom they would find objectionable.

Mr. Dunscombe was sorry that the matter had not been referred to the committee for the purpose of ascertaining from the practice elsewhere whether such an officer was necessary. In case the proposed appointment was made, they would have Dr. Power and his new assistant taking care of these thirty patients.

Dr. Power reminded Mr. Dunscombe that he and his assistants had to attend not merely to thirty patients in hospital, but to 600 or 800 healthy lunatics, a far more dangerous and troublesome class.

An application was read from Dr. Ryan, asking remuneration for his services while acting as *locum tenens* for Dr. Power.

Mr. Dunscombe moved that the claim be disallowed on the ground that Dr. Power had gone on a tour of pleasure and was not emancipated from duty.

Sir D. Norreyes seconded the motion of Mr. Dunscombe which was passed.

[The readers of the MEDICAL PRESS of the dates when these Privy Council rules were first promulgated, will be aware that we opposed them in every one of their details and in the despotic manner in which they were conceived, and have since been carried out. They were constructed at the time when the Maryboro' Board of Governors had evinced a disposition to support their visiting-physician in his complaint against a thoroughly objectionable Resident Superintendent, who was sheltered under the wing of Dublin Castle, and who was subsequently dismissed from the service. Mr. Dunscombe says no more than the truth, when he declares that they have taken "the least semblance of authority from the governors." We understand that the despotic pressure of these regulations has organised a strong movement for their repeal, and that they may probably be brought under the notice of the House of Commons next session.—Ed. M. P. and C.]

The Relative Mortality in Small and Large Lying-in Hospitals.

THE Annual Report of the Waterford Lying-in Hospital, conducted by Dr. Elliott, shows a mortality of only fifteen in 3,742 cases, and of the fifteen, only five were cases of puerperal fever.

The Postal Restrictions on Newspapers.

IT will be a satisfaction to us and to our readers to know that the powerful influence of the Society of Arts will be actively exerted during the coming session of Parliament, in obtaining a relaxation of the vexatious restrictions placed on newspapers by the Post-office.

Lord Henry Lennox in his recent address to the Society said :—

"The refusal to recognise as a newspaper anything which is not published at least every seven days, or which, for the convenience of its readers, is stitched together, seems most arbitrary and unintelligible.

"What the Society of Arts intends to agitate for, is the removal of these distinctions, and the establishment of a parcels post, by which a uniform rate of ½d. would be charged for every 4oz. and under, or 2d. a pound for everything up to a specified limit, say, that which prevails in North Germany."

That the Post-office should refuse to permit us to stitch the MEDICAL PRESS AND CIRCULAR, is quite intelligible to us. Their mandate is deliberately designed to hinder us, and all other weekly class periodicals, from availing ourselves of the advantages accorded to the daily paper. Truly, it is a liberal and large-minded policy, which enacts such restrictions for the purpose of restraining the public in their use of a great public department, professedly maintained for their convenience.

Medicine Contracts for Irish Poor-law Unions.

THE *Journal of the Irish Medical Association* in a recent issue, gives insertion to a letter in which very extraordinary statements are categorically put forward in reference to the Medicine Contracts of the Irish Poor-law Service. The correspondent says : "The idea of tendering for medicine for the sick as you would for oats and beans for your horses, is so preposterous as to require no comment, as the discriminating tact of the person tendering is well evinced by the careful manipulation displayed in arranging the prices to be attached to the 713 articles set forth in the official tender. For instance, powdered hellibore, an article in little use, is supplied to the guardians of a certain union at one farthing the pound, while bromide of ammonia, an article in frequent use, costs the same board of guardians forty-eight shillings the pound—the commercial value of the first medicine being one shilling the pound, while that of the latter is eight shillings and sixpence. That there are other equally singular anomalies in the system of tendering for the supply of medicine is apparent from the following extracts taken from the 'Tenders for Medicine' to be supplied to the North and South Dublin Unions respectively :—The contract price for tartar emetic at the North Dublin Union is five and fourpence a pound ; at the South Dublin Union one and twopence a pound, the commercial price of same being one shilling and sevenpence ; Spanish flies, North Dublin Union, sixpence per pound ; South Dublin Union, sixpence, commercial value being five shillings and fourpence ; bromide of potassium is six shillings and sixpence a pound in the North Dublin Union ; twenty shillings a pound in the South Dublin ; its commercial price being five shillings and fourpence ; powdered scammony, a very important article in the materia medica, is twenty-eight shillings a pound in the North Dublin Union, only ten shillings a pound in the South Dublin Union, whilst its real commercial price is twenty-one shillings."

The Editor in a leading article devoted to the subject gives an explanation of these anomalous charges which is very disgraceful to the contractors and the service which has permitted such gross abuses to arise. He says : "Our readers may be puzzled to comprehend the reason for these extraordinary differences in contract prices between one union and another, but if they were aware of the method pursued for selecting the tender they would easily understand the scheming encouraged by the system. When a contractor tenders for the supply he attaches to each medicine in the list the price at which he can supply it. If there were any person competent to judge of the fairness of these prices the *ruse* would be detected at once ; but as there is no person who knows anything about the price of medicines, and seldom anyone who cares to look to the effect of money-saving on the poor, the decision is arrived at by a summary manner. The cost at which the contractor offers to supply the entire list is totted up, and the contract given to the person whose figure is lowest. The contractor simply enters in the column a nominal price against those articles which he knows will never be asked for, and an exorbitant overcharge against those preparations which are most commonly used, and thus he makes allowance in the unusual medicines for the disgraceful charges in the common drugs, and, as a rule, the lower the sum total of the contract, the greater the expense to the Union when the supply comes to be paid for."

Retirement of Mr. Donovan, of Dublin.

A RETIREMENT from professional practice is not usually made a text for public notice or comment, yet we feel that there are considerations in the r emoval of Mr. Donovan from connexion with the profession which makes it right for us so to act.

In Mr. Donovan, the profession loses the last and only

apothecary in Dublin, and with his retirement expires the *régime* under which pharmaceutists devoted themselves to pharmacy, and took pride in knowing their business and sticking to it. Mr. Donovan's name was familiar to the readers and scientific men of the last half century as the associate and colleague of the first Irish physicians of his day. Pursuing his well considered course, he persistently refused either to lay claim to medical experience, though immeasurably in advance of most general apothecary practitioners in this respect, or move one step to either side of the path of science to which he had devoted himself. Farseeing, and believing in the greatness of his art, he foretold the virtual extinction of the Irish Apothecaries' Company which has arisen from their abandonment of their proper functions, and, alone, he maintained a silent and life-long protest against the theory and the policy which regards pharmaceutical chemistry as nothing better than drug-selling.

We rejoice to learn that Mr. Donovan retires from the practice of his profession in independent circumstances, and we assure him that his disinterested professional life has purchased for him the entire respect of those who can value modest self-sacrificing principle.

Closure of the India Medical Service.

Notice has been given that, consequent on information received from the Government of India, it has been determined not to hold an examination in February, 1871 for admission to the Indian Medical Service.

The Liverpool Epidemic.

Relapsing fever and small-pox have still a firm hold of the town, the latter epidemic being, in fact, on the increase, and special efforts are being made by the parochial authorities to provide plenty of proper accommodation. During the week ending Tuesday, it seems there were 311 cases of fever and small-pox admitted into the hospitals, and 369 discharged, being 1,263 inmates, against 1,321 on the previous Thursday. *The Liverpool Courier* reports that one of the medical officers has recovered from an attack of fever, but another is now laid up, as were also ten paid nurses—one of whom died on Wednesday. These facts were reported at the Workhouse Committee meeting yesterday, when it was mentioned that provision would have to be made for the growing population of the workhouse. At Toxteth park the out-door cases of relapsing fever have increased from 502 last week to 564, while the patients in the sheds had decreased from 260 to 252.

The Draft Bill for the Regulation of Pharmacy in Ireland.

We learn that the Association of Chemists and Druggists of Ireland have declared themselves positively against the Bill submitted for their approval by the Irish Apothecaries' Company. At a recent meeting of the Association it was resolved, on the motion of Mr. Erson, seconded by Mr. Hayes—

"That the Association of the Chemists and Druggists of Ireland, whilst admitting the necessity of a Pharmaceutical Society for Ireland, decline to place themselves under the control of the Apothecaries' Hall of Ireland. And that a copy of this resolution be forwarded by our Secretary to the Apothecaries' Company in answer to their circular."

Purity of Citrate of Iron and Quinine.

In the *Practitioner* the following table is given, showing the results of analyses of six specimens of citrate of iron and quinine purchased in London. According to the British Pharmacopœia, this preparation should contain 20 per cent. of ferric oxide and 16 per cent. of quinine.

No. I. . .	19·3 per cent.	17·5 per cent.
No. II. . .	20·2 „	16·2 „
No. III. . .	21·4 „	15·4 „
No. IV. . .	21·3 „	7·1 „
No. V. . .	20·9 „	4·2 „
No. VI. . .	20·4 „	4·1 „

The East London Children's Hospital has received a donation of £100 from G. E.

The Committee of the Medical Club have invited medical gentlemen who were practising in France befor the war broke out, and are now staying in England, to become honorary members of the club *pro tem*, of which privilege no doubt many will avail themselves.

Dr. Oliver, of Redcar, says the unanimous opinion of the Profession has asserted that scrofula, above all other disorders, is benefited by sea-air and sea-bathing. He has seen excellent results from the treatment of struma at Redcar. At the Convalescent Home, it would appear that these cases do best during the winter months.

The *Boston Medical Journal* protests in the following terms against the ridiculous and illiberal disability imposed on medical journals by the postal regulations:—"The British Postal Department has issued a preposterous decree that no periodical whereof the sheets are stitched together shall come under the mail-rates provided for newspapers; and material packthread being thus supplanted by metaphorical red tape, our English weekly contemporaries come to us in a disjointed form, ready to fall to pieces the moment their leaves are cut. The outrage is one demanding prompt redress, and we call on the Administration to give positive and inflexible instructions on the subject, if it ever be possible to find anyone who will accept the vacant mission to St. James."

The friends of the late Professor Graham have decided on erecting a statue of him in his native town, Glasgow. The Town Council have appointed the south-east corner of George square as the site of the proposed statue, which will be from the chisel of the eminent sculptor, William Brodie, of Edinburgh, and is to correspond with the statue of Watt, at the south-west corner of the square.

One of the London magistrates lately gave a good but a little too severe lesson on the theory of contagion to a prisoner brought before him. The prisoner had acted as a nurse in Great Titchfield street, Marylebone, to a child who died of small-pox. The parents gave the nurse the pillows on which the child slept, supposing she would destroy them, but the woman sold them to a marine-store keeper. She was fined £5, with the alternative of a month's imprisonment. Prisoner said she was destitute. The sentence was evidently far too severe; but Mr. Knox is rather given to harshness.

The President of the Dublin Obstetrical Society, Dr. George Johnson, celebrated the conclusion of his term of office on the 17th inst. by a conversazione, given at his residence at the Rotundo Hospital. The rooms were crowded with the most eminent members of the Profession in Dublin, including the residents of the Colleges of Physicians and Surgeons, and the Surgeon to the Queen in Ireland. A number of objects of Art were exhibited, and the company was entertained at supper in the course of the evening.

In a letter to Dr. Thompson Dickson from the Registrar-General of Scotland, that gentleman says that the registers of England are most imperfect, and do not contain one half the cases of illegitimacy occurring among the population. There is no obligation on anyone to register a birth, and no penalty for refusing. He believes that there are quite as many illegitimate children in England as in Scotland. More than half of the illegitimates in Scotland are subsequently legitimised by marriage of the parents. There is very little infanticide in Scotland. There is a certain amount of baby-farming, chiefly confined to girls who go out as wet nurses and give their own child to the care of a relative. We shrewdly suspect that the new Society for the Protection of Infant Life intends to make the life of maiden mothers still more wretched than it is at present in England and Ireland. The principle of "hit him hard, he has no friends," is well carried out by many social reformers.

At a meeting of the Pathological Society on November 1, Mr. Nunn showed a case of "Atrophy of the Uterine Wall, with an Intra-uterine Fibroid Growth." The cervix was quite normal, but the body was nearly absorbed. Dr. Hilton Fagge exhibited the "Liver of a Patient, aged sixty-seven, who died of sclerosis." The disease, in eighteen months, spread over the lower limbs, hands, face, and eyelids. She died of starvation, being unable to move the jaws. The skin was as hard as a board, but not glued to the muscles, and was much thickened. The internal organs were healthy, but the connective tissue of the liver, &c., was harder than normal. Mr. H. Arnott showed a case of "Cancer which had attacked an Imperfectly Descended Testicle in a Man, aged fifty." The disease was medullary. Dr. Whipham showed a case of "Rupture of the Transverse Ligament, with sudden death." The patient had always supported her head when she moved. There was caries of the cervical vertebræ. Dr. Green showed a specimen of "Pulmonary Aneurism from a Girl, aged eighteen, who died of sudden hæmoptysis." In the apex of the left lung there was a very large and rugged cavity, and below a smaller one containing an aneurism the size and appearance of a morella cherry. Dr. Tilbury Fox showed two specimens of "Madura Foot."

SCOTLAND.

Edinburgh.—The unmanly way in which a few of the junior students chose to show their dislike to mixed classes by getting up a "row," has been summarily dealt with in the police courts, and their demonstration impetuosity has, for the present, evaporated with the costs it entailed. The folly of their proceedings is equalled only by that of the friends of the lady students, who for some days past have assembled at Surgeon's Hall, to protect the ladies on leaving the anatomical rooms, a very unnecessary proceeding, and conducted with an amount of ostentation calculated to damage rather than advance the course of the female students.

Of the extra-mural teachers of midwifery, Dr. Matthews Duncan alone continues to lecture during the winter session. Dr. Duncan has for some years been in the habit of delivering a course of lectures to women during the winter months, a duty which could be undertaken this year only by combining this class with that newly formed by him for gentlemen. This arrangement has unfortunately proved distasteful to many of the students, nearly one-half of Dr. Duncan's class having withdrawn on learning that it was to be continued during this session. Dr. Duncan has a class of twenty-eight pupils, five of whom are females. Professor Simpson has enrolled sixty-seven students.

Literature.

FERGUSSON'S SYSTEM OF SURGERY.*

The fifth edition of a work on surgery by the Sergeant-Surgeon to the Queen, and President of the Royal College of Surgeons, is what any reviewer might hesitate to speak about. No writer could take up the book without feeling that he was going to learn. The idea of criticising the work of the most popular of teachers and practical surgeons, involves more than is to be expected, except at the hands of a very select few. Our readers may, however, be glad to have a few notes respecting the new edition. We therefore beg to apprise them that the work is now a goodly 8vo vol. of 750 pages, printed in clear type, and that the publishers have been good enough to have the edges cut—an improvement we wish were generally adopted. The book has not lost its *practical* character; "Each subject," we are told, "has been treated according to the author's estimate of its utility and importance," as he has every right to do, after occupying the Chair of Surgery at King's College for thirty years. Sir William Fergusson illustrates most subjects by his own practice. It is this which gives much of the real life to the work. It may be, and it will be, consulted by thousands of practitioners who are desirous of knowing the general views of the author, and a large proportion, too, of his own pupils will keep it as a handy-work of reference to the body of teaching by which they have profited. Some new matter and new illustrations have been added, to find space for which many passages of the last edition have been omitted. The author's late experience has furnished the new material. The subject of Diseases of the Jaw has been thoroughly exemplified by both drawings and cases. That of the Urinary Organs has been very carefully revised. Excision of the Scapula is illustrated by new engravings, and both pen and pencil combine to show the reader the practice of the author in the removal of enormous tumours, in which, as our readers are well aware, his skill has been associated with great success. Bearing in mind the title—"A System of Practical Surgery"—not a System of Surgery—we are convinced that this Fifth Edition will be appreciated by the Profession.

A BOOK ABOUT SHAMS.†

We congratulate the author of "A Book about Shams" on the historic and biographic information about "peculiar people" and a peculiar time, with which his book abounds. The eloquence of his pen, and the really "Greek-fire" mode in which shams—regal, legal, religious, medical, and general—are exhibited for public

* A System of Practical Surgery. By Sir William Fergusson, Bart., F.R.S. Fifth edition. London: J. Churchill and Sons. 1870.

† A Book about Shams, Relating to the Great French Revolution. By Lory Marsh, M.D. London: Ward Lock, and Tyler.

execration deserve praise, whilst for the sympathetic gaze afforded to that homogeneous tribe—shams general—should they condescend to read the volume, as pourtraying true types of their brotherhood, acknowledgement is due by them.

Were it possible for the ghost of Cagliostro, Hahnemann, or Mesmer to revisit the green plains of their former exploits, we would not be in Dr. Lory Marsh's shoes for—well, shall we say that luckless necklace, the misadventures of which he discursively treats about in so bewitching a manner as to render his book a jewel indeed.

"A Book about Shams" is prettily illustrated, printed on toned paper, handsomely bound in cloth; and we predict for it a genuine welcome—we were going to say—everywhere.

The following quotation may interest the admirers of "Petty Pills and Powders Small" :—

The Founder of Homœopathy.—Hahnemann, the founder of Homœopathy, was born in 1755, just in time to take the field with his theory of globules, and to occupy the pinnacle of fame from which Cagliostro and Mesmer were shortly to be ignominiously hurled. After a life of varied fortune, and expulsion from Leipsic as a Quack, Hahnemann settled in Paris, where he divided his labours with his wife, and lived in a state of ostentatious splendour, only equalled by Cagliostro himself. Helen Berkeley, describing her visit to the establishment of Dr. and Mrs. Hahnemann, at Paris, speaks in glowing terms of the palatial style of their residence. The liveried footmen at the door, the gorgeous furniture of saloon after saloon through which she was conducted by relays of men in plush and powder, caused her to exclaim: "I already knew something of Hahnemann's celebrity, but my opinion of his skill was marvellously fortified by the magnificent splendour of the apartments through which I was conducted." Of course, the display was made in order to dazzle the eyes and flatter the vanity of those who were seeking the great man's presence. Just as in the present day, on visiting the establishment of one of the fashionable West-End quacks, the patient is conducted upstairs and downstairs, through gorgeously furnished drawing, dining, and billiard rooms, and finally ushered into the penetralia of the owner, where he is left to wonder, like Helen Berkeley, at all the wealth displayed before him. The effect of all this show, so unlike the modest apartments of the honest practitioner, is to make the patient feel he is about to be ushered into the presence of some great Hakim, and to reconcile him to the fee that is about to be demanded of him.

CLINICAL LECTURES ON PULMONARY CONSUMPTION.*

Before we had seen these lectures we had heard much about them, and read them accordingly with the more interest. That they open up some new views, or at least enlarge upon some which had not been fully recognised, may be admitted, But we are not at all certain they will be accepted as readily as the author seems to think. For he speaks as if his views were absolutely proved, and so must be received. It may be observed too, in passing that the translator draws attention to the fact, that the late Dr. Addison held similar opinions, which, however, though published, had not received any marked notice from the profession. We may observe here, that the main point in the views of our author, consists in the idea that inflammation or inflammatory action is the basis of all phthisical disease. This idea, as has already been stated, is not original; nor indeed, we are bound to say, does the author claim it as such; for he refers to several of his own countrymen * as holding and teaching a similar doctrine; and more especially to Virchow and Buhl. But the idea leads to the use of many expressions, scattered through these lectures, which must certainly seem very strange to most physicians in these countries. The following may be quoted as examples of what we mean: "In the present stage of science there is but one kind of tubercle—miliary tubercle; and but one form of tuberculosis, and all those changes which, since Laennec, have been designated. 'Infiltrated pulmonary tubercle' are the product of chronic, especially of catarrhal, pneumonia" (page 2). Again: "In very many cases there is not a single tubercle found in phthisical lungs" (page 3). Again: "The tubercles in the majority of cases are clearly of recent origin, and have complicated the pulmonary phthisis, when it was already in an advanced stage" (page 4) and one more, he speaks of patients who, after having suffered from phthisis for years had at last become affected with tubercules. Though more might be quoted these are quite sufficient to show the way in which the author views the subject. Opining that inflammatory action is the basis of phthisical disease, and declares itself in the form of pneumonia, he looks upon the deposition of miliary tubercle as quite secondary; and hence the views taught by Laennec and held by all, we may almost say, since his time, must be abandoned. Before we speak of these views, it may be well to notice that the name given this lecture is "Pathology of Phthisis." Now, to these terms and to the way they are here applied we must make the strongest objections. And these objections are peculiarly applicable here; for the author all through, argues as if the morbid anatomy were the real pathology of phthisical disease, and speaks as if a form of pneumonia were the very foundation of the affection; and no where—as far as we are aware—does he allude to that general state of the constitution which precedes, and to our mind must precede the development of the disease. Now this arises from confounding morbid anatomy with pathology; than which there cannot be, to our minds, a greater mistake—and it seems to pervade the entire views of our author. That a something precedes the pneumonia, to which our author gives such prominence, or the formation of tubercles, is absolutely certain. Yet he no where expresses himself to this effect; but expressely states that pneumonia is, in the vast majority of cases, the starting point of phthisical disease; and at page 13 he asserts that no one form of pneumonia gives rise to the affection, but that all do so, though not equally; and this leads on to the main question: are these views correct? Is inflammation the starting point of phthisical disease, or of phthisis? or is pneumonia? The answer to these questions must, on our parts, be in the negative. We consider the views the author has advanced to be partial; and not taking that extended view of the subject which it demands, we might almost add beyond all other and, without at all wishing to dogmatise, we must, with our present knowledge, still hold the opinions advanced so long since by Laennec. Here, however, our space will not allow us to do more than make a few remarks. In the first place, we would call attention to the physical signs of phthisis, and to the slow and insidious way in which they make their advances. It is not needed now to state what these signs are. But we would ask: are they attended in the first instance in any symptoms whatever of pneumonia? Is the cough of threatening phthisis dry or the contrary? Every one knows it is the former. Would it be so if pneumonia were present? We think not; and it devolves on the author, or his adherents to tell us why, with pneumonia present, no expectoration exists. It is true, cases of pneumonia may occur without expectoration. Such have come under our own notice. But they are known to be far in a way the exception—not the rule. Speaking of the absence of expectoration in the early stage of phthisis, reminds us too, that at this period, no crepitus is heard. To us it seems

* Clinical Lectures on Pulmonary Consumption. By Felix von Niemeyer, Director of the Medical Clinique, and Professor of Clinical Medicine in the University of Tubingen. Translated by permission of the Author, from the second German edition, by C. Baumler, M.D., Member of the Royal College of Physicians, Assistant-Physician to the German Hospital, and to the Hospital for Diseases of the Chest, Victoria Park. The New Sydenham Society, London, 1870. Pp. 71.

* The names of Hoffman, Simon, A. Clark, Sanderson and Wilson Fox may be mentioned in connection with the pursuit of the subjects in these countries.

very difficnt, if not impossible, to reconcile this fact with the supposed presence of pneumonia; and on the contrary when crepitus is heard, it is well known that it must have been preceded for months by what are known as the earliest signs of phthisis. Neither is the crepitus of phthisis of the same character as that of pneumonia, as every one knows. But again, the locality which tubercles occupy, in the vast majority of instances, is known to be the upper lobe of the lung. We take it for granted, the author does not dispute this. But how is it to be reconciled with the equally well recognised fact that pneumonia in similar number of instances affects the lower lobe of the lung. If there were no other argument than this one, it would be enough to shake, in our minds, the entire views of the author; and we would add we are quite at a loss to reconcile it with one of the conclusions at which he has arrived, and which we copy from the work:—

"The consolidations and destructions of the lung, which form the anatomical basis of pulmonary phthisis are, as a rule, the products of pneumonic processes; and the more abundantly cellular elements accumulate in the alveoli, and the longer this accumulation persists, the more readily does a pneumonia lead to phthisis, because the cheesy metamorphosis of inflammatory infiltrations is thereby favoured." (Page 24.)

If these be the correct views, those who differ from them must truly be far astray. We firmly believe, however, they are not so; but that all experience and positive knowledge derived from the study of the morbid anatomy of tubercular disease are opposed to them. There is just one supposition which would explain the author's views; which is, that the disease presents different characters in Germany, from what it does in the British Isles. In other words, pneumonia may be an infinitely more common disease there than with us, and that its common *habitat* is the upper lobe of the lung. We must say, however, that this idea, while not impossible, seems to us in the highest degree improbable. We believe too, that pneumonia occurs 100 times for once that it has, or seems to have, any connection with the deposition of tubercle. If the two diseases stood to each other in the relation in which the views of the author would lead us to believe, the connection must have been long since recognised; and we would not have the numerous and separate works on the two affections which exist. Besides all this pneumonia is as little of a fatal disease as phthisis is the very reverse, but our limits prevent us following out this aspect of the question.

In keeping with the views held by the author, our readers will not be surprised to learn he holds the idea that phthisis is not an hereditary disease. "I do not hesitate to say, in spite of all assertions to the contrary, that it is by no means sufficiently proved that tuberculosis, in the strictest sense, is an inheritable disease." Such are his words, which agree, almost as a matter of course, with the views previously advanced; for a man who holds that inflammatory action is every thing in the production of tubercular disease need not go further for causes. But is this idea true? Is it the experience of English or Irish physicians? What has been the result of statistics as bearing on the question? We need scarcely tell our readers it has been the very opposite opinion which has been arrived at, and that it has been proved, as clearly as the nature of the subject admits, that phthisis is an hereditary disease. Very much more could be said on this particular part of the subject, but it does not seem necessary.

In concluding this notice of these important lectures, we must say that the views advanced by our author seem to us untenable. They do not agree with the well ascertained fact of the essentially constitutional character of phthisical disease. In all our experience, the earliest physical signs of the development of tubercle prove the pneumonia is not, at that period, present. The *habitat* of tubercle, as far as the lungs are concerned, is, in the vast majority of instances the upper lobes; whilst that of pneumonia is the lower lobes. The hereditary nature of pulmonary comsumption is, in these countries at least, an acknowledged fact. In truth the author's views seem to us to have been founded entirely on exceptional cases; and being such are "not proven."

Correspondence.

CELIBACY AMONG SOLDIERS AND OTHERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some very able writers in your journal have endeavoured to show forcibly the evils of seduction. I have always thought this a superficial way of looking at the question of prostitution, baby-farming, and infanticide. In my view, there is the constant force of the sex-appetite, which, unless attended to, inevitably causes ruin and wide-spread misery. Doctors know better than any others how strong the appetite is, and what dangers we incur by attempting to check it partially or entirely. Thus, Sir B. Brodie, at the meeting of the Social Science Association in Birmingham, said, that the evils of celibacy were so great that he would not mention them, but that they surpassed those of prostitution. Mr. Holmes Coote, who was, and perhaps, is still surgeon to Bedlam Hospital, gave it as his opinion before the Medical and Chirurgical Society some years ago, that the diseases caught from prostitutes were, by no means, so deadly as the results of celibacy, as witnessed in the wards of lunatic hospitals; and Sir W. Jenner gave evidence to the same effect before the Committee of the House of Lords, when enquiring about venereal contagion.

My own experience entirely confirms the truth of these statements of our learned brethren; and I cannot, by any means, look with complacency on the late marriages, which are so much in vogue among a large portion of our countrymen, and especially countrywomen, even although perfect chastity be observed by both the males and females before the legal contract is entered into. I don't know whether there is not more diseases, on the whole, produced by the late marriages of Britain, than by the dissipation of the French population. Insanity is a terrible phenomenon, and is doubtless the result in very many cases of the present customs of celibacy. Now, the theory of our army, as at present existing in this country, is, I submit, according to these principles, quite monstrous. We, as a nation, require a certain number of able-bodied men to remain constantly under arms, in order to defend us from aggression, and we have an idea that we have a right to keep these men in a state of absolute continence (that is the theory), in order that they may be in constant readiness to start off to any campaign at a day's notice, without the impediments of wives and children—such is the theory—now for the practice. These men do *not* live in a state of abstinence, none do so less than soldiers, perhaps. And, thus, we condemn a number of men full of leisure time, and *ennui*, to pass an existence dangerous to the happiness of the female population of the country, on account of a *theory*, which will not hold water,—viz., that it is "quite easy for every one to live in a state of celibacy, with a little moral control."

The whole of this is a lie, and has led to prostitution and the ignoble Contagious Diseases Acts. In future, if we can but look Nature calmly in the face, we shall come to confess that *all* human beings, male and female, have a perfect right to claim from any society which wishes to merit the names of civilised, their fair share of love, offspring, and domesticity. Soldiers, priests, and women are very hardly treated by our modern trashy theories, and should all have their partners, as well as the rest of the citizens. The only thing we, of the Scientific School cannot allow of is, large families. No advance in morality is compatible with the starvation caused by such rapid breeding as early marriage has hitherto produced in Great Britain and notably in Ireland. But we find that celibate soldiers don't fight so well even as men with wives and babies; and hence, we must think of giving our soldiers these desirable companions. The Germans get on very well with their campaign, remembering that comfort and affection await them when they return home.

I do not, in any way, mean to be intruding on the theory

of any church, in saying what I do. I am not, I believe, bound to agree with the tenets of any one church. I speak merely as a medical man, and, moreover, as an individual who admits of no arguments which are not addressed to my intellect. Infallibility, I lay no claims to, and if others do, I cannot accept their adjudications. Nature cares little for our systems or churches, and if we desire to be happy, we must make them square with Nature, and not desire to set ourselves in opposition with the laws of animal life.

I remain, yours faithfully,

CHARLES R. DRYSDALE,
M.D., M.R.C.P.L., F.R.C.S.E.

99 Southampton row, London, W.C., Nov. 21.

Medical News.

Glasgow University Medical Society.—The following gentlemen have been elected office-bearers for the current year :—Honorary President, Prof. Dickson ; President, Robert Sinclair ; Vice-Presidents, William Sneddon and James Glendinning ; Corresponding Secretary, G. B. Clark ; Secretary, John Highet ; Treasurer, Robert Murdoch ; Committee, W. C. Watt, James Smith, William Grant, Hugh Miller, William Leith, George Thompson, and James Adams.

Apothecaries' Society of London.—At a Court of Examiners held on the 24th instant the following gentlemen were admitted licentiates, viz.—Messrs. W. W. Atkinson, of Cheshunt, Herts ; C. F. Gray, of Newmarket ; E. J. Pugh, of Waltham Abbey ; and A. C. Simon, of St. Helier's, Jersey.

"Studies for the Time."—To go back to the Crimean war itself, Russia continued her aggressions because she did not believe we would fight. The Czar's ambassadors advised him that England, casting aside her old traditions, had entered upon a new epoch, which had for its motto, "Peace at any price." Lord Russell's encouragement of Denmark's resistance to the demands of Prussia and Austria led to the merciless slaughter of that plucky little State. The tragedy thus commenced had its principal scene at Sadowa ; and Paris besieged is the sequel to Sadowa. England out of the way, the ambition of the more powerful nations of Europe breaks out with demoniac force and heat. It is the mission of England to stand between these contending passions, and the present condition of Europe is the penalty of our withdrawal from that grand *rôle* among nations which a mysterious Providence has assigned to us.—*Gentleman's Magazine.*

Presentation to Dr. Wm. MacCormac from the Students of the Queen's College, Belfast.—The students of the Queen's University, Belfast, assembled last week for the purpose of presenting an address to Dr. William MacCormac, on the occasion of his removal from Belfast for residence in London. Dr. Wm. MacCormac, on entering the theatre, was received with loud and long-continued cheering. Mr. Murphy, B.A., assured Dr. MacCormac that every word which it contains expresses the very sincerest convictions of the students, and that, whether reference is made to his skill and experience as a surgeon, or his courtesy as a gentleman, or to the disinterested efforts which he has made in ameliorating the sufferings of his fellow creatures, the words used have been cold and measured compared with the warm sentiments of admiration entertained for him, alike for the many estimable qualities of his head and heart. The address and reply having been read, the meeting adjourned.

Medical Mayors.—The following members of the profession have been elected mayors for 1870-71 :—John Griffin, M.D., for Banbury ; Evan Pierce, M.D., for Denbigh, fifth time ; George Green Sampson, M.R.C.S. Eng., for Ipswich, re-elected ; Lawrence Spencer, M.D., and F.R.C.S., Eng., re-elected for Preston ; William F. Rooke, M.D., for Scarborough ; Frederick Chambers, M.D., for Margate ; Joseph May, F.R.C.S., for Devonport ; Fortescue J. Morgan, M.R.C.S. Eng., for Stamford ; Richard Ley, M.R.C.S., for South Molton ; and Dr. John Tibbits, M.R.C.S., for Warwick.—*The Times.*

The Birth Place of Contagions.—The following account by Mr. Parkinson occurs in a contemporary, and shows us how we may account for the spread of cholera from India to Europe :—The Pilgrim Trade—"I've never been to Jerusalem, and I never mean to go, thank ye !" said the English engineer of the Russian steamer, "though I've been up and down these waters for these fifteen years, touching at Jaffa, and bein' within a day's ride of Jerusalem, as you may say, these twenty years. We see a precious deal too many o' them nasty pilgrims on board this boat for me to want to visit a place I know to be chock full of them, for I hate pilgrims, mind you, as I hate pizon, and I'd give a good deal to keep altogether out of their way." . . . . The good steamer, the 'Emperor Alexander,' is "in the pilgrim trade." . . . The pilgrims were packed in little dens like those in which menagerie keepers show their wild beasts, save that there were no bars. Two stories of these dens ran along both sides of the deck, and in each of them were exactly as many human beings as it would hold. Here were ragged priests in long black robes and fur caps like frouzy grey muffs, peasants in sheep-skins which had been sewn on them years before, and had never since been taken off, small Russian farmers and their wives and children, Turks, Armenians, and Egyptians, all bound for one or other of the ports of the Holy Land. They cooked, ate, slept, and prayed in their dens, and the pilgrims in their abject filth and disorder, almost justified the abhorrence of the English engineer. They all appeared to be miserably poor, The Russian peasant who was a serf yesterday, and is a beast of burden hampered with superstition to day, has been putting by small sums all his life for the grand work he is now upon. Before he started on his sacred errand he satisfied the authorities of Odessa, the port he took his passage from, that he had sufficient means to carry him to the Holy City and to bring him back, and he is now fulfilling the darling wish of his heart, for he is about to earn the sanctity only to be acquired by a pilgrimage to the Holy Places, and is already calculating on the relics he will take back. The Mahomedan in turban and clean robe, who turns to Mecca and prostrates himself the prescribed number of times, profoundly indifferent to surrounders and lookers on ; the black-robed Armenian, who lies on his stomach to engrave something in the Greek character upon a crumpled and dirty piece of water ; his brother ecclesiastic, who is even more ragged and less cleanly than himself, and who is absorbed in his book of prayer ; and the swarthy, handsome silk-merchant from Damascus, who is on his way to join his brother's warehouse at Jerusalem, and who talks "shopi" as 'cutely as a Yorkshire bagman, were types which were repeated many times in the course of our tour round the ship's decks. . . . . Some well-dressed Russian pilgrims, who were our fellow-passengers in the saloon, had decidedly boiled their peas. They were bound for the Holy Places too, but they lived royally and drank hard, and were as little like religious enthusiasts as loose speech, loud voices, and convivial habits could make them.

Gleanings.

Extraordinary Keloid Tumour of the Neck.

WE have had an illustration drawn and engraved, that our readers may the more readily follow the report of this extraordinary case, which we glean from the *New York Medical* :—

This case, the author remarks, is the most wonderful of its kind I have ever beheld. This negro is from North Carolina, and is twenty-eight years of age. He is of immense muscular development, and, save his affection, looks to be the embodiment of health. This immense tumour which encircles his neck, like an Elizabethan collar, is an affection of the skin, first accurately described by Alibert in 1810, and called keloid, from its fancied resemblance to a crab. This growth is hard, semi-elastic, and looks very much like an enlarged cicatrice resulting from a burn. The inhabitants of hot countries seem particularly prone to this affection. I remember assisting Professor Gross to operate upon a creole from the Bermudas, when this growth occurred on the ear, following the boring of the lobe of the ear so that rings might be worn. I have at this time a patient under my charge upon whom I have twice operated for this affection, a coloured man, but each time the tumour has recurred. Burns and scalds are common causes of keloid,

You see many of these morbid growths are scattered over the body of this man. Keloid, though rarely, if ever, degenerating into malignancy, is troublesome on account of its unvarying recurrence. When excised, it nearly always returns, and its second growth is generally worse than the first. This man's father had a similar affection, which the patient states disappeared spontaneously. (?) In consequence of prolonged pressure, part of this growth around the neck, has taken an ulcerative action, and you see the pus dropping upon the man's shoulder. A section of a keloid tumour, under the microscope, shows fibres interspecting each other in every possible direction, intercepting cells, or spaces occupied by plastic matter, of a softer nature. To the naked eye it presents a whitish, homogeneous aspect, or, if the man be very old, very much the appearance of an unripe pear or turnip. It creaks slightly under the knife, and is of a dense, firm consistence, with little elasticity. Hardly any vessels are perceptible in its interior, but the surface of the growth is very vascular, so that if I would cut this man the hæmorrhage would be tremendous.

There is no remedy but the knife or écraseur. The intense disfigurement to which the affection subjects this man, to say nothing of its inconvenience, would warrant any feasible procedure to free him from the growth. But the subject demands more careful thought than I have yet had time to give it. In conclusion I would mention that this growth is of eight years duration.

Clearing of Muddy Water.

Dr. C. Schlæsing states, in an article in the *Comptes Rendus*, that waters contaminated by floating particles of clay may be readily clarified by small quantities of salts of lime. It is well known that the waters of rivers, after a heavy fall of rain or snow, and sometimes throughout the winter, do not become quite clean by deposition, even if left undisturbed in large reservoirs for a long space of time. The author recommends the addition of 1-1000th part of chloride of calcium for one part of water (or seventy grains to the gallon), a quantity which effects clarification in a moment. The precipitated substance can be readily separated by filtration. Other salts of lime, such as the nitrate and bicarbonate, and caustic lime, effect the same object.

Hydrate of Chloral.

An octogenarian lady took morphia by the advice of her physician thirteen or fourteen years ago. She continued to take it of her own accord afterwards, and has persisted in the habit thus acquired. She now takes about two grains of sulphate of morphia every night. In consequence of an attempt to discontinue its use, awhile ago, she became restless, excited, nervous, and sleepless, with symptoms not unlike those of delirium tremens. After two or three days and nights had elapsed without sleep, Dr. Clarke gave her fifteen grains of chloral hydrate. This quantity calmed her. A second dose of the same amount was followed by a sleep of several hours. Unfortunately, the habit of taking morphia could not be broken up, and she resumed her customary dose at night, This has quieted and comforted her, but has not always induced sleep. When it has not, fifteen grains of chloral have always been sufficient to put her to sleep in a short time. Less chloral was required to produce sleep when morphia had been previously administered, than when the latter article had not been given.—*Boston Medical and Surgical Journal.*

Dr. Clarke, in the same journal confirms Dr. DaCosta's views, and states that a fourth of a grain of one of the salts of morphia, followed in an hour by fifteen or twenty grains of hydrate of chloral, will produce a greater anæsthetic and hypnotic effect than a larger dose of either of them given alone. In many cases, where a certain dose of morphia is sufficient to allay pain, but not to produce sleep, it is better to follow the morphia by hydrate of chloral than to repeat the former.

Obituary.

JAMES LUMLEY EARLE, M.D., M.R.C.S.

It is with much regret that we have to record the death of Dr. Lumley Earle, of Birmingham, at the early age of thirty years. A few weeks back Dr. Earle, while apparently in good health, was seized with an attack of hæmoptysis, which recurred several times, and ushered in rapid phthisis. After obtaining the membership of the London College of Surgeons and the M.D. of St. Andrew's in 1861, Dr. Earle, who was a student of King's College, and had acted as Resident Assistant to the Obstetric Physicians at King's College Hospital, came to Birmingham to fill the office of Resident Surgeon Accoucheur to the General Dispensary. His appointment he held for some two years, and devoted himself with great ardour to the study of obstetrics. So well did he utilise his opportunities that while residing at the Dispensary, he published a valuable series of paper "On the Mammary Signs of Pregnancy and of Recent Delivery" which were afterwards published in a separate form. In 1863 he commenced private practice in Newhall street, Birmingham, and soon afterwards was elected Acting Physician to the Children's Hospital, and Obstetric Surgeon to the Queen's Hospital. The former appointment he held at the time of his death, the latter he resigned some two years ago when the midwifery department of the Queen's Hospital was abolished. The revival of the appointment of Obstetric Surgeon at the Queen's Hospital in October last, led Dr. Earle, to look forward with confidence to again filling his former position, and it was during the worry of the contest for the appointment that he fell ill. It was strangely enough on the very day on which the committee for securing his election were to meet for the first time, that the first attack of hæmoptysis occurred. Dr. Earle was a frequent contributor to the Medical Journals, and in our own pages and in the Obstetrical Transactions, there are many papers from his pen. In 1865 he published a work "On Flooding after Delivery and its Scientific Treatment," which was characterised by the same learning and practical good sense, as all his other writings. He had considerable mechanical ability, and devised several ingenious midwifery instruments, among which we may mention a new Pelsimeter, and a modification of the transfusion apparatus. Almost his last appearance if not the last, at a public meeting was at the Queen's College conversazione, when he exhibited a new case of obstetric instruments, which certainly was one of the most perfect we have seen. As a practitioner of midwifery, Dr. Earle was most skilful and successful, and from the high estimate of his ability entertertained by the profession, he would, no doubt, have attained a very high position. Dr. Earle was well known at the Medical Societies of Birmingham, and for some years acted as Secretary to the Midland Medical Society. He was also appointed early in his career a member of the Council of the Obstetrical Society of London. His early death when the difficulties had all begun to disappear, and an abundant harvest of success was just opening to his view, has caused much regret among all his professional brethren by whom he was highly esteemed, alike on account of his personal character as his professional ability.

A NEW PHASE OF MALINGERING.

THE story of the Sleeping Beauty a Yankee competitor with the Welsh Fasting Girl for the money of the unwary, will be familiar to our readers. As the story goes, the patient (now twenty-nine years of age), enjoyed average health until the age of eight years, when she had "recurring intermittent fever," as a result whereof she fell into a condition of almost constant somnolence, lasting nearly twenty-three hours out of the twenty-four, and accompanied by certain choreic movements of the head and shoulders—a condition which is alleged to have continued for more than twenty years, or until the present time.

The phenomenon in question having been taken by her exhibitors to St. Louis, and her case brought to the notice of the St. Louis Medical Society, that body appointed a committee to investigate the case. These gentlemen report :—The patient, so far as we can learn, has taken no medicine, for a number of years, with a view to the relief of the alleged condition. Remedies and means were proposed, such as, in our judgment, were safe, but they were declined. It was proposed to watch the case for forty-eight consecutive hours, which was also declined. We procured means by which the case could be observed in the night, by persons selected by the committee, and we report unanimously that on three nights there was no paroxysm at ten o'clock p.m.; and she appeared to sleep as naturally as any one. Notwithstanding the positive assertions that the paroxysms continued during the night as well as the day, they did so only at such times as they were in the room *by appointment*; we respectfully submit the unanimous opinion that it is a case of collusion, misrepresentation and systematic pretending, for the purpose of deceiving.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

⁂ We must also request our Correspondents to write only on one side of the paper and in *legible* characters. We are often compelled to consign MSS. to the waste-paper-basket merely because it is illegible.

CORRESPONDENTS not answered in the current Number are requested to look to the Notices the following week.

TO SUBSCRIBERS.—The publisher has received a Post-office Order for £2 5s., without the name or address of the sender, who would oblige by forwarding it to the London office, that credit for the amount may be given, and a receipt sent.

AN ARMY SURGEON.—The subject shall receive our best attention.

DR. DWYER.—The Minute and letter to hand. Shall appear next week.

MEETINGS OF THE LONDON SOCIETIES.

THURSDAY, Dec. 1st.

HARVEIAN.—8 P.M. "Apoplexy," by Dr. T. Ballard.

FRIDAY, the 2nd.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.—At 7½ P.M. Dr. Whitmore will read a paper "On the results of Sanitary Legislation on the Health of the Metropolis and our present urgent Sanitary requirements,"—On Saturday Dec. 3rd, at 5 P.M. The President, Dr. Richardson, F.R.S., will deliver the Anniversary Address, "For the Future of Physic."

MONDAY, the 5th.

MEDICAL.—8 P.M. Ordinary Meeting.

TUESDAY, the 6th.

PATHOLOGICAL.—8 P.M. Ordinary Meeting.

VACANCIES.

Manchester Royal Infirmary.—Senior House-Surgeon. Also two Physician's Assistants. Salary £80 guineas for each appointment.

Southport Infirmary.—Resident House-Surgeon. Salary £120 per annum.

Scottish National Institution for Imbecile Children, Stirling.—Superintendent.

Farringdon Dispensary, London.—Resident Surgeon. Salary £70 per annum.

Clinical Hospital, Manchester.—House-Surgeon. Salary £60, with board.

Hartley Wintney Union.—Medical Officer. Salary £80, with extra fees.

Poor Law Unions, Ireland.—The Commissioners will elect a Superintendent Apothecary, at a salary of £500 a year, with residence. (See advertisement).

Carlow Union.—Midwife for the Bagenalstown District. (See advertisement).

APPOINTMENTS.

ANDERSON, W., F.R.C.S., Surgical Registrar to St. Thomas's Hospital.

BERESFORD, Mr. F., Assistant House-Surgeon to the Staffordshire General Infirmary.

BOTT, T. B., M.D., Medical Officer of Health for Bury, Lancashire.

CHRISTIAN, J. G., M.R.C.S., Medical Officer for the Pelham District of the Bishop Stortford Union.

COLLIE, A., M.D., Resident Medical Officer to the Homerton Fever Hospital.

COUTTS, J., M.A., M.D., Medical Officer for the Cuckney District of the Worksop Union, and the Third District of the Mansfield Union.

DAVIES, D., L.K.Q.C.P.I., Surgeon to the Almshouses, Gwydyr Charity, Llanrwst, and Certifying Factory Surgeon for Llanrwst.

EVANS, E. T. R., M.R.C.S., District Surgeon to the Salford and Pendleton Royal Hospital and Dispensary.

GAYTON W., L.R.C.P.Ed., M.R.C.S., Resident Medical Officer to the Homerton Small-pox Hospital.

GRATTAN, J. S., L.K.Q.C.P.I., Assistant Medical Officer to the West Derby Union Workhouse, Walton.

GREEN, Mr. J., House-Surgeon to the Royal Infirmary, Edinburgh.

HORSLEY, H., M.R.C.S., Surgeon to the General Hospital, Croydon.

IRVINE, J. W., Medical Officer to the West Derby Union Workhouse.

MAHON, T., L.K.Q.C.P., L.R.C.S.I., Medical Officer for the Crossmolina Dispensary District of the Ballina Union, Co. Mayo.

PRIESTLEY, H., L.R.C.S.Ed., Assistant House-Surgeon to the Sheffield General Infirmary.

REID, R. B., L.R.C.S.Ed,, Medical Officer to the West Derby Union Workhouse, Walton.

ROBERTS, W. L., M.R.C.S., additional Resident Medical Officer to the Bradford Infirmary, Yorkshire.

SHARP, J. A., L.R.C.P.L., M.R.C.S.E., House-Surgeon to the Derbyshire General Infirmary, Derby.

Birth.

ASHE.—On the 21st inst., at Sprackburn House, Letterkenny, the wife of Isaac Ashe, Esq., M.B., of a daughter.

Marriages.

CHURCHILL—FORBES.—On the 15th inst., at Weston-super-Mare, George Fleetwood Churchill, M.D., Army Medical Staff, to Mabelle, daughter of the late Rev. Wm. Forbes.

EDWARDS—THOMAS.—On the 22nd inst., at Llanbadrig, Anglesey, E. P. Edwards, Surgeon, of Plas-Llanfigael, Llanfachreth, to Miss Margaret Ann, second daughter of O. Thomas, Esq., of Neuadd, Llanbadrig.

Deaths.

BELL.—On the 13th inst., Wm. Bell, M.D., of Garstang, Lancashire, aged 81.

BRABANT.—On the 19th inst., at Bath, Elizabeth, relict of the late R. H. Brabant, Esq., M.D., aged 89.

DOW.—On the 21st inst., at Keith, John Dow, M.R.C.S., of London.

EARLE.—On the 23rd inst., at Birmingham, James Lumley Earle, M.D., youngest son of the late Lieut.-Colonel J. L. Earle, of the Indian Army.

FOX.—On the 10th inst., at Bristol, after a brief illness, Emily, the beloved wife of Dr. Wilson Fox, of London.

MCRAE.—On the 24th inst., at Holloway, Louisa, relict of the late John McRae, M.D., R.N., aged 79.

TAYLOR.—On the 18th inst., Francis Taylor, M.R.C.S., of Romsey, aged 59.

WEST.—On the 17th inst., at Alford, Lincolnshire, R. U. West, M.D., aged 60.

IDIOPATHIC TETANUS—CONTINUED USE OF TINCTURE OF BELLADONNA—INTERCURRENCE OF ANTHRAX—RECOVERY.

(Under the care of G. H. Porter, M.D., F.R.C.S., Surgeon to the Queen in Ireland.)

Patrick McCluskey, thirty-seven years of age, the driver of a bread cart, was brought to the Meath Hospital on the morning of the 15th October, 1870, suffering from well marked symptoms of tetanus. There was no history of a cut, wound, bruise, burn, or injury of any kind, to account for his condition. His wife was closely questioned with reference to the origin of the affection; and she corroborated her husband's statement, that "there was nothing to bring it on but the will of God." He was examined immediately after his admission, as soon as he had been got into bed; the body was curved and stiff, the head retracted, the lower limbs rigidly extended, and their muscles in a condition of tense symmetrical spasm, the abdomen was hard, the jaws about half an inch apart, face flushed, conjunctivæ congested, skin perspiring profusely; the articulations of the neck, hips, knees, and ankles could not be moved, actively or passively; the power of voluntary movement was not lost in the upper extremities, although considerably impaired, and the muscles of these parts exhibited a much slighter degree of tonic contraction than did those of the lower extremities. His respiration was not hurried, nor his pulse rapid, although very variable in its rate. Frequent spasms occurred spontaneously, or were excited by the slightest irritation or disturbance; in these, the opisthotonos was increased, the alæ nasi became widely dilated, and the tetanic expression was well marked. He could swallow liquids, but the act of deglutition often excited a convulsion of the muscles, and he set about drinking in a most cautious and deliberate way. He spoke in a thick and indistinct manner, like a person half intoxicated, partly from the close approximation of his jaws, and partly because, as was afterwards ascertained, he was under the influence of hydrate of chloral when admitted. He was at once given ten drops of the tincture of belladonna, and the dose was ordered to be repeated every third hour; a flannel wrung out of a hot infusion of tobacco was laid upon the abdomen; he was directed to have a liberal allowance of wine and beef-tea, and means were taken to have the ward in which he lay kept as quiet as possible.

The antecedents of the case were these:—He had to give up his employment of driving the bread cart on Saturday, the 1st of October, because he did not feel able for the work; during the previous week he had become unable to eat, because his jaws were stiff, and it was very difficult to swallow solids, meanwhile he could drink without any trouble, and during that week he lived principally on liquids, mostly of a highly stimulating nature. He then lay at home for a fortnight before his admission to the Meath Hospital, and at this time was carefully attended to by Dr. Devine, who treated him with bromide of potassium, hydrate of chloral, and turpentine embrocations. According to his own account, he had always been a healthy man, but had latterly "become nervous from smoking and drinking." For a long time his daily allowance of whiskey had been a very liberal one, and he was more than moderate in the use of tobacco, as his consumption of it averaged an ounce a day. There was no account of any cold or wetting, nor could any assignable cause for the disease be discovered upon the closest and most frequent investigation.

In the afternoon of the day of his admission (15th of October) his temperature was carefully registered; it did not exceed 99·8 Far., a circumstance which gave a favourable aspect to the case; the pulse at the same time ranged from 68 to 84 in the minute, its rate being constantly accelerated upon the occurrence of spasms. He made no complaint of pain except in his back, and he did not allude to this unless questioned on the subject. He was quite free from the epigastric pain so frequently complained of in tetanus, as extending from the pit of the stomach under the xiphoid cartilage to the back, and forming the initial

point of spasms. The absence of this pain, regarded by Chambers as the pathognomonic symptom of tetanus, would point to the slight or non-implication of the diaphragm in the tetanic spasm—a view confirmed by the great tranquillity of his respiration. In the intervals between spasms, he lay stretched out stiffly on his back, breathing without noise, and answering questions in an intelligent but indistinct manner. In the evening, he was given a large enema of gruel and mucilage, containing two ounces of castor oil and half an ounce of tincture of assafœtida. Two hours after this he got two drops of croton oil by the mouth. The enema was skilfully administered by the resident pupils, Mr. Middleton and Mr. Bowers. Great difficulty was experienced in introducing the enema tube, owing to the spasmodic condition of the muscles of the rectum and perineum. The tube was grasped by the forcible contraction of the sphincters; the parietes of the rectum appeared to be in contact, and contracted to such a degree as to incarcerate the finger of the operator, causing a well-marked congestion of the ungual phalanx. In some cases of tetanus, each effort to introduce the enema tube has provoked such dangerous spasms that it has been found more judicious to give up the attempt, especially as sudden death has occurred during the operation; in such cases the preliminary use of chloroform would appear desirable.

No fæcal evacuation resulted from these means, but he was relieved by the expulsion of great quantities of offensive gases. He passed a bad night, being afraid to let himself go to sleep, from an apprehension of suffocation —"for fear he would be choked." On one occasion before admission, as he was dropping asleep, his jaw snapped suddenly, and he bit his tongue severely. The tincture of belladonna was administered regularly through the night every three hours by Mr. Middleton.

On the morning of the 16th, his pulse reached 120, but was at times much lower; the respirations were about 32 in the minute, but varied in proportion to the rapidity of the pulse; the trismus was increased, only the tip of the tongue could be seen; the opisthotonos was more strongly marked. The dose of tincture of belladonna was increased to twelve drops every third hour, and he was removed into a small quiet ward where there was but one other patient; a bolus of ten grains of calomel, the same quantity of jalap, and one drop of croton oil was made up with butter, and put on his tongue with the aid of the handle of a spoon, and an ice bag was applied to the spine and fastened on with tapes. The bolus given at ten a.m. began to produce large fæculent evacuations at noon (his bowels had not been opened for five days), and continued to act during the afternoon, dislodging at the same time immense quantities of wind, to the patient's great ease and benefit. He got some sleep the following night, but observes that as he is dropping asleep spasms come on and awaken him; in these spasms the pain or cramp "runs up from his feet to his body."

On the 17th, his pulse did not exceed 106; there was no aggravation of the trismus or opisthotonos, nor had the spasms increased in frequency or severity; he "felt that he was no worse," and spoke most gratefully of the relief he had experienced by the evacuation of the bowels on the previous day. At 6.30 p.m. his pulse was 80, full and regular, and his temperature in accordance with the state of the circulation; he can move no part of his body except the upper extremities, the muscles of the face, and to a very slight degree his toes. He takes in the twenty-four hours ninety-six drops of tincture of belladonna, twenty ounces of wine, and beef-tea in unlimited quantities. He suffers from continued thirst. The temperature of the small ward he was now in was much more equable and elevated than that of the larger one he had been in, a point on which Dupuytren and others have laid much stress in the treatment of tetanus. This night he got twenty grains of hydrate of chloral, and had "some real sleep" for periods of an hour at a time.

On the 18th, the excitability of the spinal cord was evidently diminished, although the retroversion of the head and trunk continued in a marked degree; he was "certain the spasms were less frequent than they were." Questioned as to their intensity and duration, his answer was that "not one in every twenty comes in earnest now." He described these "earnest" spasms as travelling upwards from his feet to his throat, then "they catch him there and choke him;" his toes "straighten out" at the outset of a spasm. He feels sore across the loins, as if his back were breaking across there. The abdomen continues hard and tympanitic, notwithstanding loud and frequent deliveries of flatus *per anum*. In the afternoon of this day he brought on a very violent spasm by stretching out his hand to reach a urinal, which was on a chair beside his bed; he was semi-asphyxiated, becoming "black in the face," according to the account of his companion, who was greatly frightened, and thought "he was off." The spasms which occurred subsequent to this very earnest one were much milder than usual; he had a good night, the best since his admission, sleeping for a couple of hours at a time, without any narcotic.

Oct. 19th.—Pulse was 95. No relaxation of the tonic spasm of the muscles of the trunk or jaws. An observation was made on the rigidity of the abdominal walls. He remarks that his belly is soft, until some one handles or percusses it, then it becomes rigid, and remains so for as long as ten minutes. When about to be handled the muscles seem even to anticipate the touch, and to become rigid before any actual impression is made on them, showing that the great increase of reflex excitability suspends the inhibitory influence of the brain, and the order of things is reversed, the spinal cord ruling supreme over the cerebrum. The ice-bag has been hitherto diligently applied to the spine, but was now discontinued, as an incipient anthrax was discovered on the back between the vertebræ and the posterior border of the left scapula; pressure by strapping with opium plaster was at once applied to the part, and a bolus of eight grains of calomel, the same quantity of jalap, and one drop of croton oil was administered, which acted effectively. At 6.30 p.m. he had a bad spasm, which affected the muscles of the larynx; chloroform, which was kept close at hand for such emergencies, was applied with benefit; he passed the night well, getting "two good sleeps."

Oct. 20th.—Pulse 96; the trismus abating; is able to open his mouth better; the opisthotonos continues; he complains much of the anthrax; his throat was feeling dry, and the dose of tincture of belladonna was reduced to five drops three times in the day. His account of the spasms is that "some heavy ones come now and then, but though they last longer, they are not so severe as those he has had; he has not five or six now for the ten or fifteen he used to have in the hour."

The following day (21st) he had a violent seizure at 8.30 a.m., occasioned by his movements to try and relieve the pain of the anthrax; he was able now to move his head a little from side to side, and the retraction is perceptibly less. The bowels were moved without the use of medicine. As he had never made any outcry or complaint of pain when attacked by the spasms, nor seemed to suffer from the continual cramp of the muscles, enquiries were made on this subject, and his answer was, that the "pain *was* bad, but that he was not chicken-hearted enough to roar." Such an enquiry was a reasonable one, as Sir G. Blane mentions a case of tetanus, in which the spasms were unattended by pain, even to the last moment of existence. In that instance the cramps were accompanied by a tingling and agreeable sensation, and the accesses were attended by feelings of pleasure, and a strong tendency to laughter.

On the 22nd he could open his mouth wider and could turn on his side, and keep in that position; hitherto he had lain on his back. This change of position was a great comfort to him, taking so much pressure off the anthrax, which was now assiduously poulticed with linseed meal and port wine.

On the 24th, the belladonna was omitted for the present. He had used, in the ten days since his admission, 724 drops of the tincture. This day he was able, for the first time, to bend his hip-joints, and to sit up in bed for a very short time. The mouth can now be opened wide enough to let the dorsum of the tongue be seen.

On the 26th and 27th he had several attacks of spasmodic cramp in his feet and legs. His legs became numb and cold towards evening, and at night "he does not know his feet are on him, till the warmth of a hot jar brings them to him." The belladonna was resumed for three days (27th, 28th, 29th), on account of these "cramps," during which time he took ninety-five drops; it was then finally discontinued. The total quantity which he used was 819 drops, and at no time were his pupils dilated beyond a medium size. The slough of the anthrax came away at this time, its separation may have given rise to the "cramps" which distressed him a good deal; the deep cavity which it left was soon filled up with healthy granulations under the influence of careful strapping and the constant use of equal parts of castor-oil and of Canada balsam.

On the 29th, he was able to open his mouth to its full extent, to eat a chicken, to bend his knee-joints, and to lift his head slightly off the pillow. The pulse was 96 and regular; his principal complaint, now that the anthrax was healing rapidly was, of general muscular pain, and soreness in every part of his body, as if he had been severely beaten with heavy sticks; he describes this feeling as "a sore stiffness," and clearly distinguishes it from the "old pain which came on suddenly and in shocks."

On the night of the 30th he did not feel comfortable, and at 11 p.m., what he described as a "regular solid spasm," came on him, it "came on him in a strain, till it strained the whole frame as if he was in a vice, or some powerful thing was pressing him down on the bed, he could not stir or move, and perspiration teemed off him," this spasm continued till 3 a.m., he was wide awake the whole time. For several successive nights he had minor attacks of cramp, but never any more severe spasms, the muscular soreness gradually diminished.

On the 14th of November he was up for the first time, sitting in a chair for a few minutes while his bed was being arranged. He caught cold on this occasion.

On the 15th a feverish attack set in with headache and giddiness, and lasted till the 24th, when it subsided after two profuse critical sweatings. During this feverish attack, his pulse and temperature were higher than they had been in the course of the tetanus; the pulse averaging 104, and the temperature 102° F.

On the 25th, the pulse was 87, and the temperature 97·6 F.

On the 28th, he could move all his joints quite freely, the soreness of his flesh had disappeared, and a very slight stiffness across the loins was the only relic of the violent muscular spasm which remained. He had almost completely lost the facies tetanica, the stiffened and aged expression of features which, in life and death, so frequently stamps the subjects of tetanus. His pulse and temperature were those of health, appetite and spirits good, and he felt himself to have quite recovered.

If any apology be necessary for having given this case somewhat in detail, it may be pleaded that tetanus from unknown causes is not a common occurrence, and every such case is very worthy of record. The term idiopathic, as Le Gros Clark has well pointed out, is not to be accepted as synonymous with spontaneous or causeless, there being many irritations unseen by the surgeon and unfelt by the patient, fully capable, under certain predisposing conditions, of exciting fearfully the reflex power of the spinal cord. Furthermore, although the so-called idiopathic form of tetanus is, in this country, generally more amenable to treatment than is the traumatic form, yet, the published records of idiopathic tetanus in Ireland show a frightful mortality in this affection. In India, it appears to be the more fatal form of the disease, as Dr. Peet, Professor of Surgery in the Grant Medical College, Bombay, found that while 72·2 per cent. of the admissions for traumatic tetanus ended fatally, the mortality in the idiopathic form reached to 76 per cent.

ON SOME CHRONIC VARIETIES OF SYPHILITIC ULCERATIONS.

By Mr. Morgan, F.R.C.S.I,

Surgeon to Mercer's and to the Westmoreland Lock Hospitals; Professor of Surgical and Descriptive Anatomy, R.C.S.I.

(Continued from page 434.)

Chronic Ulceration of the Urethra.

A remarkable and rare form of this ulceration has occurred in two instances at the urethra, destroying the canal up to the very orifice of the bladder, and causing distressing incontinence.

A most marked example, occupying both the urethra and vaginal orifice, has been under my observation from time to time for upwards of two years. The patient had been in the hospital suffering from pains, ovarian irritation, and a most severe hysterical attack—contrary to the received idea that women of this kind are not subject to hysteria, most marked cases, on the contrary, being not unusual in the wards of the hospital.

M. K., aged twenty-five, was admitted October 16, 1867; had a sore some years ago, which was healed by the application of lotia nigra. She received another sore twenty months since, which formed around the vagina, and continued all that time, its character being that of smoothness, density, insensibility, and tardiness of progress; it is not auto-inoculable. The illustration shows the remarkable characters of her case, and the severe ulceration of the urethra, which caused incontinence and at intervals considerable pain in micturition—the whole tract being a sheet of ulcer. The sore at the vaginal orifice was analogous in appearance and character to that occupying the urethra, and had existed now upwards of one year and eight months; for one year and two months being under actual hospital observation, and every effort made for its cure. She has never had any skin or throat affection, but had suffered severely from pains, particularly of the sternum and ribs.

She gradually improved, and regained, to a great extent, the power of retaining the urine; the cicatrix of the original sore being very dense and smooth.

Ulceration of the Rectum.

A very remarkable instance of ulceration of the rectum, depending, probably, on the deposition of gummatous matter in the subcutaneous, and also on the direct extension from the exterior, has been under my observation for nearly two years. The appearances during life were most marked, and were the cause of the greatest misery.

The patient was the subject of a well marked chronic sore, which she stated had existed for more than two years; during several months she was living irregularly with the sore on her. She had been under my observation for more than ten months, during which time she was affected with ulceration of the rectum of a most perverse and extensive character; the sore was of great extent as revealed by the speculum, with hard edges, presenting several inches square of ulcerated surface. There was a most copious discharge, and pain on going to stool; but no tendency to contraction, on the contrary, rather the reverse, apparently from partial destruction of the sphincter—the genital sores preceded that of the rectum. There were no constitutional signs beyond the formation of gummata on the body; the ulceration of the rectum commenced as an ulcer exactly as did the chronic genital sores themselves.

This patient was most benefited by arsenical treatment, and the use of gr. xxv. of tannin as a suppository each night; and, from time to time, the ulceration would improve very considerably. The drain on the system was, however, most severe, vast quantities of mucous pus being discharged, and, occasionally, tinged with blood.

The patient finally sank, suffering from all the symptoms of amyloid liver and cachexia.

A careful *post-mortem* examination was made, and the rectum was removed; on opening it, two immense sheets of ulceration extended upwards on each side, fully twelve inches long, and from two to three inches wide; the edges were marked and dense; the surface of the ulcer was smooth, and had destroyed the sub-mucous tissue; there were patches of the same kind of ulceration far up in the sigmoid flexure, but diminishing in size as the intestine was examined upwards; the liver was thoroughly amyloid, and there were two gummata, deep seated on the leg. There was no intra-vaginal or intra-vesical sore.

Mr. Paget (Sydenham Society, 1865-66), has described similar forms of ulceration; and, as in this case, remarks the diminution of the ulcerations according as the intestine is examined higher up; he also remarked "the sharp even defined edges not undermined." The appearances in this case were just so; but the ulceration was more extensive, and gave the appearance of the mucous and submucous tissue having being gouged away smoothly by some sharp instrument, leaving the edge boldly cut, and resembling in a minor degree the sores on the labium. The disease was beyond question of nearly two years' duration. In this case I have no doubt the combination existed of the ulceration extending from the outside, and also of the formation higher up of the gummatous form of ulceration. During life, I frequently examined with a large speculum the extensive sheet of ulceration, and dressed it over with strong caustic and tannin solutions; there was not the slightest stricture, as in the case given by Mr. Paget, where it was obstinate; nor in the cases given by M. Gosselin, which so resemble, in many particulars, the account given by the late Mr. Calles, of what he termed the schirro-contracted rectum, and where he alludes so particularly to the mucous discharges.

Another case has also come under my notice, where the ulceration of the rectum was of much the same character, but not quite so extensive.

The patient was aged thirty. Had had some years previously a sore and suppurating bubo, followed by the birth of a dead child. She subsequently got a few gummata, and suffered severely from pains. By several weeks' active treatment with escharotics, injections, and tannin suppositories, the ulceration much improved, and the patient has not been since seen; but is supposed to have been perfectly cured. Here, also, the ulcer had the characteristic edge and smooth surface, and there was not the slightest stricture. This distressing and obscure affection is of much practical interest—its tediousness and obstinacy being almost as trying to the surgeon as it is exhaustive to the patient.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XV.

PRECIPITATION OF SEWAGE WITH THE SALTS OF ALUMINA AND IRON.

THE salts of alumina and iron have been the subjects of numerous patents for the disinfection of night-soil and sewage. The preparations of alumina, for example, are mentioned in the patents of Siret (1843), Browne (1850), Stothert (1852), Pinel (1856), Manning (1853, 1854, and 1855), and others; and the compounds of iron are claimed in the patents of Deboissieu (1762), Briant (1824), Sire (1837), Barounet (1845), Dubois (1846), Brown (1847), Ellerman (1847), Browne (1850), Gilbee (1852), Dimsdale (1853), and others.

All these inventions rest on the well-known property of the recently precipitated oxides of iron and alumina, to combine with the organic matter contained in the solutions in which they are precipitated, and to form insoluble compounds therewith. In the case of alumina, its affinity for organic colouring matters is so great that it is not merely used as a mordant or fixing agent for such colours when applied to fabrics, but it is also employed to precipitate these matters from their solutions, and to produce the insoluble compounds called "lakes." Even when alumina and oxide of iron are used in their denser condition, as they exist in common earth or loam, they have the power of absorbing and fixing soluble organic matters, as well as the compounds of ammonia and phosphoric acid. It is natural, therefore, that these substances should have been proposed for the purification of sewage.

The *salts of alumina* claim our first attention, because they are somewhat more effective as defæcating agents than those of iron; and the earliest practical suggestion for their use is in the patent of Mr. Stothert, dated the 17th of April, 1852. He therein recommends that fresh made caustic lime, sulphate of alumina, or sulphate of zinc, and a combination of animal and vegetable charcoal, obtained from sewage or night-soil, should be employed for the precipitation of the substantial parts of sewage water, so as to produce a valuable manure. This process was tried in the year 1857 by Dr. Hofmann and Mr. Witt, when they were experimenting on London sewage, and they found that it rapidly caused the flocculation and precipitation of it. Forty gallons of ordinary sewage were treated with five ounces of lime and ten ounces of the mixture of charcoal and sulphate of alumina. The lime, which was first added to the sewage, produced considerable aggregation of the suspended matters; but the aluminous preparation caused a marked increase in the flocculation and separation of these matters, forming them into a dense precipitate which rapidly subsided. The effect of this treatment of the sewage was as follows:—

Constituents per gallon.	Raw sewage	Effluent Water.
	Grains.	Grains.
Dissolved matters . . .	107·60	87·73
Organic matter . . .	52·36	37·56
Mineral ditto . . .	55·24	50·17
Oxygen required for oxydation	—	—
Matters in suspension . .	52·49	0·00
Organic matter . . .	36·40	0·00
Mineral ditto . . .	16 09	0·00

In this way the whole of the suspended matters were removed, together with 19·87 grains of the dissolved matters, and of this 14·8 were organic, so that nearly 58 per cent. of the total amount of organic matter in the sewage was thus removed. The precipitate when dried contained 1·21 per cent. of nitrogen (= 1·44 ammonia), 3·97 phosphoric acid (= 8·6 bone earth), and 35·97 organic matter, and it was

worth two guineas per ton. According to Mr. Stohert, a ton of the materials, costing 30s., will make two tons of manure.

In the year 1853, Mr. James Alexander Manning obtained a patent for defæcating and separating certain matters from sewage by means of animal charcoal, alum, and carbonate of soda and gypsum, the precipitate being mixed with certain waste products, rich in phosphates, so as to form manure; but as the use of alum was found to be expensive, he improved the patent in the following year (1854) by employing a waste product called "soft sludge," from alum works. This is the deposit which forms during the first boiling down of the rough liquors obtained from alum shales in the manufacture of alum, and it consists of basic and other sulphates of iron and alumina. Later still, in 1855, he again improved the patent and cheapened the production of the alum compound by the application and use of alum slate, alum shale, alum schist, alum stone, and alum ore, and other aluminous minerals and earths, as precipitating and clarifying agents for cleansing sewerage matters. The method which he recommended for the preparation of these shalts, &c., was much the same as that used in the early part of the ordinary process for making alum whereby the material called "soft sludge" is obtained; and in this manner an aluminous compound is easily obtained at a price, according to Mr. Manning, of about five shillings a ton. He also recommends in each of his patents that powdered caustic lime and animal charcoal should be used with the aluminous compound: his directions are that the soft sludge, or other aluminous preparation, is first to be added to the sewage, and then, while it is being agitated, the powdered caustic or unslacked lime and animal charcoal are to be thrown in; after which it is to be allowed to subside in the precipitating tanks. The process was carefully tried in Edinburgh and a few other Scotch towns, and it was reported very favourably of by the late Professor Penny, of Glasgow, who found that it defæcated sewage in a very satisfactory manner, and gave a product which contained 2·22 per cent. of ammonia, 2·05 of phosphate of lime, and 43·72 of organic matter. This product, according to Dr. Hofmann and Mr. Witt, is worth £1 16s. 5½d. per ton. Another sample of the precipitate, from the sewage of Pinckston Burn, analysed by Dr. Penny in 1854, contained 31·74 per cent. of organic matter (with 0·728 nitrogen, = 0·884 ammonia), and 13·57 per cent. of phosphate of lime. According to Dr. Penny this was worth 35s. per ton.

More recently still a like process has been patented by Mr. Lenk for the defæcation of sewage by means of a solution of crude sulphate of alumina, called "alum cake." We examined a sample of Mr. Lenk's solution in the year 1865, and found that it contained about 12 per cent. of alumina. A gallon of ordinary London sewage required 24·5 grains, by weight, of the solution to defæcate it, and in twenty minutes the flocculent precipitate had completely subsided, leaving a perfectly clear and almost inodorous supernatant fluid. In the year 1868 the process was tried for more than a week on the sewage of Tottenham, and the results were quite satisfactory to the local authorities, for they say that "a cask of water taken from the tank became, after settling, perfectly clear and free from all smell, two gold fish living in it for some weeks." From three to three and a-half cwt. of the chemicals were used per day for about 700,000 gallons of sewage, or one ton per week, at a cost of £6 10s. The process was examined by Dr. Voelcker, who analysed the several products, and reported that "Lenk's Deodorising Liquid certainly effects a ready precipitation of suspended sewage matters, and at the same time removes a very large proportion of obnoxious soluble refuse matters. The sample of deodorised Tottenham sewage, examined by me, certainly was very satisfactorily disinfected. Sewage, after efficient treatment by Lenk's process, in my judgment, may be poured into a water-course without causing a nuisance like ordinary sewage." According to Dr. Voelcker's analysis, the following was the composition of the raw sewage and the defæcated sewage water:—

Constituents per gallon.	Raw Sewage.	Effluent Water.
	Grains.	Grains.
Dissolved matters	91·10	63·39
Chloride of sodium	14·46	14·21
Ammonia	9·76	4·23
Organic matter	42·30	9·70
Phosphoric acid	3·77	trace
Matters in suspension	367·70	3·01
Organic matter	225·60	0·77
Mineral ditto	142·10	2·24
Total ammonia obtainable	24·237	5·103

From which it appears that the process removed almost the whole of the suspended matters, and 27·71 grains of the dissolved matters, 32·6 grains of which were organic. The precipitate when dry contained 1·86 per cent. of nitrogen (= 2·26 ammonia), 4·91 phesphoric acid (= 10·71 of bone earth, and 42·26 of organic matter. "In a perfectly dry state," according to Dr. Voelcker, "the deposit would be worth to the farmer about £2 2s. a ton. In such a perfectly dry state, however, it is not possible to obtain it on a large scale. Sufficiently dry to become powdery, the sewage deposit would probably retain from one-fourth to one-third its weight of water, and in that condition, the sample would be worth from 25s. to 30s. a ton as manure." Looking, therefore, at the profit of the results, it would seem that, if all the sewage of Tottenham produced, as in the present instance, at least 392·4 grains of dry deposit per gallon of sewage, the 4,900,000 gallons per week, must furnish nearly 123 tons of dry deposit, which, with one-third of its weight of water, to form a commercial product, would weigh about 164 tons—worth according to Dr. Voelcker, 25s. a ton. So that for an outlay of £6 10s. per week, for a ton of Lenk's chemicals, there would be realised a product werth £205. Even supposing that the suspended matter of the sewage amounted to only 38·2 grains per gallon, which is the average of London sewage, the return would have been sufficiently large to have deserved the attention of the Tottenham Local Board of Health, seeing that they were not only the custodians of the public health, but were also under an injunction not to pollute the river Lea with their undefæcated sewage. All the attention, however, which it received from them was, a memorandum to the effect that "Lenk's process was tried for more than a week at the Tottenham works, with very fair results." They did not even go to the trouble of ascertaining what was the real effect of the process on the effluent water, or what was the nature of the deposit obtained. This, how-

ever, is only one example of the many ways in which the carelessness and parsimony of our local sanitary boards are constantly bringing the sewage question into the region of difficulty and doubt; and, in this case, if it had not been for the investigations of Dr. Voelcker, it would most probably have been said that the process of Lenk had been tried at Tottenham and had failed.

Other processes have been proposed for the defœcation of sewage by the aid of an impure sulphate of alumina and iron, made from sulphuric acid and common clay, but, as these will be best examined after the consideration of the several processes for defœcating sewage by means of the salts of iron, we shall defer them for the present.

Hospital Reports.

METROPOLITAN FREE HOSPITAL.

On Tuesday, Nov. 22nd, Mr. Sheffield operated on a patient suffering from fistula in ano. A young woman, aged twenty, was sent to Dr. Sheffield by Dr. C. R. Drysdale. She had been under the care of one or two surgeons previously, who had treated the case as if it were an incomplete fistula. She had suffered for two years. There was a fistulous opening about three inches from the margin of the anus, through which a probe could, with some difficulty, be thrust up to meet a finger on the bowel about 2" above the sphincter. Bichloride of methylene was administered by Mr. Ruju, and the fistula completely laid open by a very extensive incision. Forty drops of laudanum were administered after the operation, with the injunction that twenty drops were to be given at night, with an ounce of chalk mixture thrice a day for some days. Mr. Sheffield has under his care a case of fungus of the testes; but, on consulting with Dr. Drysdale, as the man had a cavity in his left lung, it was thought useless to operate. We observed a well-marked case of tertiary syphilis in a strong, healthy-looking man, aged forty, who dated the time of contagion thirty-five years back to a gonorrhœa, or small sore, about which he seemed to have but small recollection. There were extensive nodes over both tibiæ and two depressions in the skull from loss of bone, also, there were large exostosis on the bones of the forearms. Otherwise the patient seemed by no means cachectic. The Metropolitan Free Hospital contains less than forty beds, and seems well suited for operative surgery, as the wards are small, and the patients comfortably attended to and contented. There is some idea, we hear, of a new site, close to the terminus of the Great Eastern Railway, being selected for a new hospital. We trust that the committee may take a hint from the late Sir J. Simpson's writings, and make the new hospital a congeries of small buildings instead of a palatial edifice.

ROYAL OPHTHALMIC HOSPITAL, MOORFIELDS.

In a recent visit to this hospital, we saw Mr. Bowman perform the old flap operation for cataract on the left eye of an old woman without the use of chloroform. The patient did not seem to suffer very great pain, and we hear that such is the case generally in such operations. The cornea is not very sensitive, and as the flap is confined to that structure, chloroform is hardly required in many cases. We have very rarely indeed, seen the old fashioned operation performed at the Moorfields' Hospital since the previous performance of iridectomy seems all but universal at that institution in operations for cataract. We have, indeed, heard it stated by one of the most distinguished surgeons there, that the advantages of the last-named process are very great, both because the flap in the old operation was liable to slough, and because of the risk of prolapse of the iris a few days after that process. Mr. Bowman, also, excised a piece of cornea from a patient suffering from corneal cornea, putting in a suture to keep the parts together.

ROYAL FREE HOSPITAL.

At a recent visit to this hospital, we saw a patient who had just been treated for severe stricture of the urethra by Holt's plan of rapid dilatation. Patient, a man, aged thirty-five, had applied to Dr. C. Drysdale on account of painful micturition and complete impotence. For diagnosis, that gentleman passed a catheter and found that the man had a very narrow stricture, only admitting No. 1 gum elastic. Mr. Hill performed Holt's operation on Saturday, and the man could make a full stream on Monday, and left the hospital on Wednesday quite well, with a *promise* to return to have the catheter passed occasionally. In the wards was a woman, aged thirty, or thereabouts, with a large growth attached to the left scapula, and extending into the axilla, but not attached to the tissues in that region. Mr. J. D. Hill proposed to excise part of the scapula and remove the tumour, which he deemed to be cartilaginous in nature. The new operating theatre, due to the munificence of a worthy gentleman whose heart must be in the right place, is now open, and there are few theatres in the London hospitals where more cases of important operations may be witnessed.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIFTY.

Tuesday, November 22nd, 1870.

Dr. Burrows, F.R.S., President, in the Chair.

John Harley, M.D., F.R.C.P., read

A THIRD COMMUNICATION ON THE ENDEMIC HÆMATURIA OF THE SOUTH-EASTERN COAST OF AFRICA, WITH REMARKS ON THE TOPICAL MEDICATION OF THE BLADDER.

An almost daily opportunity of watching a case of this disease for nearly a year enables the author to give precise information concerning, firstly, the prostatic form of the disease and its treatment; and, secondly, the structure and development of the parasite. The prostatic form of the disease is attended by an intermittent discharge of venous blood, never exceeding a teaspoonful, and always mixed with urine, recurring after variable intervals of from two to fourteen days, and continuing for several days in succession. The morbid appearances are confined to the last tablespoonful of urine, which contains the blood and casts (composed of mucous or blood) of the passages in which the parasites lie. Apart from the passage of blood, and the egg-bearing casts, there was no inconvenience—no impediment to the flow of urine, nor the slightest irritation of the genito-urinary apparatus.

The treatment was, at first, general, consisting in the use of such remedies as iodide of potassium, henbane, &c., which are eliminated unchanged by the kidneys. This general treatment affected the parasite to a limited extent only, and was, therefore, supplemented by local medication in the form of injections of strong infusions of wormwood and quassia, emulsions of oil of male fern in these solutions, and of solutions of iodide of potassium and some other salts. The author describes the effect of each of these drugs, and relies most of all on iodide of potassium, which was given in quantities varying from ten to thirty grains in five ounces of infusion of quassia as a daily injection. Evidence of the absorption of this remedy was manifest, and the effect was very beneficial; and by the intercurrent use of injections of oil of male fern, the parasitic products with which the tunnels in the mucous membrane are stuffed were thrown off and the parasites destroyed. Morbid products, including portions

of the adult animals, and laminated corpuscles, derived from the prostate, are figured and described.

With a view to its detection in the waters of the infected districts, the author has very carefully described and delineated the embryo of the parasite, which is a little ciliated animalcule strongly resembling some of those found in stagnant water in this country. He says: "I have several times succeeded in liberating simultaneously from the egg as many as twenty embryos, and watched their movements in a drop of water under the microscope. No sight can convey, either a more vivid impression of the activity of animal development, or a more complete realization of the energy of parasitic life. It is an interesting display, but its general attractiveness is certainly not increased by the unavoidable reflection that the tissues and fluids of the human body may readily become the abode of these lowly animals."

Experiments were made to determine whether the parasite may be developed from ova introduced into the body. From negative results, and from other facts, the author concludes that, as a rule, this does not happen, from some cause which prevents, or too long retards, the liberation of the embryo from the egg. He is, however, inclined to think that if the hatching be timely effected, or if the liberated embryo be artificially introduced into certain parts of the body, more especially the bloodvessels, its further development into the adult parasite may proceed.

As to the primary mode of invasion, the author mentions the fact that the colonists of the infected districts are early attacked by a peculiar kind of boil, which passes into an indolent ulcer, and which, ultimately healing, leaves a large and indelible scar. He thinks it very probable that these boils result from the insertion of ova beneath the skin in the act of bathing, and that the subsequent progress of the ulcer and the infection of the genito-urinary organs, is due to the liberation of embryos (which may readily occur upon the naked surface of an ulcer), and their convection or ascent to the pelvic organs along the veins which lead to them.

The PRESIDENT spoke of the great value of the researches which Dr. Harley had, now for the third time, communicated to the Society; and said that, possibly, other diseases attended with hæmorrhagic or serous discharge from mucous membrane, might be due to parasitic invasion.

MR. JOHN WOOD inquired whether there had been any opportunities of *post-mortem* examination of the prostate in these cases, and whether the parasite invaded any other part of the urinary organs.

MR. FAIRLIE CLARKE suggested the application of the solid nitrate of silver to the prostatic portion of the urethra.

DR. SYMES THOMPSON inquired as to the extent of country in South Africa over which the disease prevailed.

DR. WEBSTER inquired whether the disease prevailed chiefly in high or in low localities. He believed that loss of blood was more common at elevated than at low situations, and under low barometric pressure. He inquired also the state of the water.

DR. CHURCH asked whether anything was known about the stages of development of the parasite; and suggested that it might require two hosts.

DR. HARLEY, in reply, said that he hoped shortly to receive more detailed information from a practitioner in Natal about the *post-mortem* appearances, and also about some other points that had been raised. The parasite was sometimes located in the pelvis or veins of the kidney; and, when thus situated, its embryos were apt to form the nuclei of oxalate-of-lime renal calculi. The disease was chiefly seen in the district of Port Elizabeth, where the water was said to be "brackish," and was almost confined to stations within twenty miles of the coast, and elevated not more than 300 feet above the sea level.

GEORGE JOHNSON, M.D., read

A CASE OF TRAUMATIC TETANUS; RECOVERY AFTER THE REMOVAL OF A FOREIGN BODY FROM THE WOUND, AND THE ADMINISTATION OF CHLORAL.

H. N.——, aged thirteen, a newspaper boy, was admitted into King's College Hospital on the 24th June. Three weeks before, whilst getting over a hedge, he ran a sharp piece of wood into his thigh. He stopped the bleeding by tying a handkerchief round the thigh. The wound soon healed, and he is confident that no portion of the pointed wood remained beneath the skin. About nine days before his admission the lower jaw began to feel stiff; this gradually increased, until it interfered with mastication. Then the muscles of the trunk and limbs began to be affected with spasm, and he came into the hospital.

On his admission he was well nourished, with a healthy colour. There was a peculiar expression of the face, resulting from spasm of the occipito-frontalis, corrugator supercilli, and other facial muscles. He could separate the incisior teeth only to the extent of about half an inch. There was some rigidity of the abdominal and erector spinæ muscles, and movement of body occasionally increased this rigidity to a painful degree of spasm, the pain being especially severe in the back. The spasm also implicated the muscles of the legs. The temperature, pulse, and respiration were normal.

At the upper third of the thigh there was a cicatrix about half an inch long, the scar and the tissues beneath felt unusually hard, and pressure caused considerable pain. It was suspected that there might be some foreign body beneath the skin, therefore chloroform was given, and an incision made through the cicatrix by the house-surgeon, Mr. Whitmore, who discovered and removed a small dark mass; this proved to be a pieee of woollen stuff from the boy's trousers, which had been driven in and lodged beneath the skin. The piece of wool was about the size of a small pea. A poultice was applied to the wound, and during the next twenty-four hours no medicine was given. There was continuous rigidity of the muscles, with occasional paroxysms of spasm and pain. He was now ordered to take fifteen grains of chloral-hydrate, at first every four hours, afterwards at longer intervals. Between the 26th June and the 9th July he had twenty-four doses of the chloral, amounting in all to 360 grains. The symptoms gradually subsided, the spasms became less frequent and less severe, the last slight attack of spasm occuring on the 13th July; the wound healed, and he was discharged cured on the 27th July.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, NOVEMBER 16TH.

PROFESSOR BENNETT, President.

MR. ANNANDALE showed—1. Parts illustrating condition of hip-joint some months after an unsuccessful excision; 2. Parts removed in excision of knee-joint; from extension of the disease, amputation had afterwards to be performed; 3 and 4. Bones removed in excision of the os calcis; one specimen exhibited well marked tubercular disease, the other necrosis; the bone was thickened and dense; 5. Tumour removed from the lower jaw, partly cystic and partly fibrous; 6. Preparation illustrative of a case of croup in which tracheotomy was performed. The child died forty hours afterwards.

DR. CADELL exhibited—1. An apparatus used at Lyons in the treatment of club-foot; 2. An apparatus for reducing to the straight position anchylosed knee-joint, by means of gradual and constant elastic traction.

DR. GRAINGER STEWART showed—1. A man presenting a well marked example of the pseudo-hypertrophic paralysis of Duchenne. The limbs were greatly hypertrophied, but weak, the connective tissue being increased, while the muscular fibres are nearly destroyed; 2. A man suffering from aneurism of the aorta. The tumour pressed upon the œsophagus and recurrent laryngeal nerves, and, from the dilatation of the right pupil, the right sympathetic was also involved.

DR. CHIENE communicated a "Case of Obturator Hernia." The case occurred in the practice of the Cowgate Dispensary. The affection was met with more commonly in women than in men, and, when diagnosed, has been once or twice relieved. The present case was that of a woman, and had proved fatal, because not observed soon enough. It was a case, indeed, in which an absolute diagnosis, during life, was impossible. Dr. Chiene showed a diagram and pathological preparations illustrating the nature of the case. It was a triple obturator hernia. No similar case, he believed, had been previously observed or reported. The Fallopian tube on one side was carried into the sac, along with the peritoneum and two inches of ileum.

DR. JOSEPH BELL made remarks laudatory of Dr. Chiene's paper, in the course of which he mentioned, that the present advanced condition of surgical science entitled the experienced surgeon to cut into the abdominal cavity in cases of ileus,

not only when the seat of obstruction had been accurately diagnosed, but in those cases also where the cause and position of the obstruction were doubtful. He justified these remarks on the ground, that recent observation had shown that the peritoneal sac was much less liable to inflammation from surgical interference than was supposed.

Dr. HANDYSIDE asked why in this case the weakest point in the abdominal wall was not the inguinal canal. The obturator foramen had become the weakest point, how did this happen? Had the patient prolapsus of the uterus? Had she suffered from hæmorrhoids? These questions were all connected.

Mr. ANNANDALE called the attention of the Society to the fact that pain passing down the inside of the thigh was a prominent symptom, in some cases of this kind, and, in fact, was diagnostic of the patient's condition, as Dr. Chiene had remarked. The hernial tumour stretched the obturator nerve.

The PRESIDENT confirmed the statements made by Dr. Bell. He referred to a case which had come under his own observation, in which had surgical interference been resorted to, the life of the patient, he had no doubt, would have been saved. In this case he had requested a surgeon to cut into the cavity of the abdomen, but the surgeon had refused, alleging that such a proceeding was contrary to the rules of surgical practice. The evidence of strangulation in this instance was undoubted. Dr. Bell went as far, however, as to advocate exploratory interference in uncertain cases.

Dr. GRAINGER STEWART observed as a result of his experience as pathologist to the Royal Infirmary, that he had no doubt many lives might have been saved, in cases of ileus, by surgical interference.

Dr. ARGYLL ROBERTSON read a paper "On Albuminuric Retinitis."

Dr. MATTHEWS DUNCAN and others testified to the frequency of the disease during pregnancy.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of the above Society, held on the 11th ult.,

Dr. CLAPTON, President, in the Chair.

Dr. CARR read a very interesting paper

ON PURGATIVES, THEIR GOOD AND EVIL.

of which the following is an abstract:—

Dr. CARR endeavoured to show the value of purgatives when given with judgment, notwithstanding the almost universal condemnation of them; and the evil they are capable of doing in the hands of the unskilful. The once popular and favourite "black draught" has been left out in the cold, with its companion the "lancet"—both ostracised by the existing race of medical men.

In a former lecture, Dr. Carr brought before this Society the subject of bleeding, and endeavoured to show that as a remedy it was still entitled to our confidence; that there were certain conditions of disease largely benefited by the abstraction of blood; that its omission in some cases permitted the patient to die, whose recovery might be favoured by bleeding. In a similar spirit, and with the same objects in view, he asked the attention of the Society to the consideration of the claims of purgatives; in the assurance that in the hands of careful, prudent, and reflecting physicians, they will be found as valuable as in days of old; whilst at the same time, he was ready to allow that many evils might result from their injudicious use.

Previous to entering on the main question, Dr. Carr very briefly reviewed the anatomy and physiology of the various organs engaged in alimentation, dwelling specially on the nerves of the bowels—cereberal and sympathetic; on peristalsis, which he illustrated with diagrams; on the extent and special characteristics of the mucous membrane; on the glandular structure of the bowels, and the various sources of fluids provided as solvents of the food, with those special provisions for carrying the excreta *per vias naturales*. He estimated the food taken at about thirty-five ounces per diem, thirty of which are absolved and five left as true excreta. All the processes engaged in alimentation, beginning with mastication, were carefully and briefly dwelt on, as aiders and abettors of assimilation, and finally of defæcation. The proper food of man, taking his teeth as a guide, was insisted on as essential to maintain the body in health, one great test of which is proper defæcation, and the subject of our future remarks.

Doubtless, if man lived in a state of nature, taking his simple food, &c., he would not merely enjoy, as a rule, uninterrupted health, but would need little help from art. But, as man ordinary lives at variance with the laws of nature, it follows that he does require occasional assistance. Habit, in spite of improper diet, will do much to correct the evils of domestication and civilization. The child or man who pays his regular "visit" will usually find it rewarded by relief. Still, in many cases, there is need of aids to defæcation to remove the miseries and the ill consequences of constipation.

In the lower animals, who are subjects to domestication, and who, like ourselves, suffer from torpor, it is no uncommon thing to see them eat grass—not natural food to dogs or cats, but which they are prompted to do by the results of domestication.

It is not unworthy of remark that homœopathy "entirely discards the use of purgatives on the ground that the body is not only marvellously perfect as a whole, but that every separate organ is adapted in an equally admirable manner, to the performance of its peculiar functions." If the bowels be confined, *let them alone*. "The only legitimate aperient is an enema of water, gruel, or the like."* Now, surely, if the rectum, one part of that body which is marvellously adapted to perform its functions, requires help when it fails, the other portions of the stomach may require the same help when they fail. Or applying the rule of help to any organ when it can't perform its functions, is simply to carry out the common sense of medical aid. Surely, if any individual is the subject of discomfort from the failure of obtaining daily relief, and some simple remedy will induce it, common sense says apply it; and having once used this remedy, experience approves its continuance when the occasion occurs.

Reason, however, goes further than this, and asks for preventitive measures—a dietary and habits which favour the daily or bi-daily relief. This good habit of emptying the rectum daily used to be insisted on by Dr. Bailey, of Edinburgh, in this language: "Gentlemen,—Ever remember, never forget, twa things—first, to pray to God; second, to visit the goddess."

No doubt, a dietary capable of nourishing the body, and yet of favouring daily or bi-daily relief, is very desirable, and may be readily discovered. In the case of young children who live mainly on milk and farinaceous food, and who are torpid, the substitution of cream for milk is of great value; the omission of casium as a food, and the substitution of butter, proves a great boon. In children, who partake largely of animal food, the decrease of this, and the increase of vegetables, will effect the desired change; or fruits, baked apples, prunes, and the like, will be followed by good. The torpid state of young people, middle aged, and aged, will often be cured by eating brown instead of white bread, or drinking a tumbler of water early in the morning. Oatmeal porridge, with cream or treacle, has proved a great boon to many habitual torpids. Above all, habit does much; the forced visit paid immediately after breakfast will often induce, if persevered in, the daily relief; and, if repeated in the evening, will be followed by an equally satisfactory result. Regular walking, in addition to change of diet, will also do much to effect a cure. Should, however, these fail, recourse must be had to drugs, and of these, usually, the mildest are the best. It is also worthy of remark, that all forms of aperients answer best, if taken at bedtime. Thus, among the laxatives, castor oil is the most reliable; and a teaspoonful taken at bedtime for a night or two will usually produce free defæcation. Among the salines, sulphates of magnesia and potash are the best; and the former combined with taraxacum, the latter with rhubarb, form excellent cathartics. The most valuable of the acrid cathartics are senna and jalap, both of which require to be combined with carminatives. If hydrocatharsis is desired, bitartrate of potash should be given with jalap, or elaterium may be used. For removing evident hepatic affections, the various forms of mercury may be given, notwithstanding the opinions entertained by Dr. Hughes Bennett.

As a record of the value of purgatives in special cases, we possess no better book than that of Dr. Hamilton, who wrote in 1805. Dr. Carr's experience supports this writer, and he further remarks that habitually torpid bowels are always accompanied by more or less of disturbed health, an unhealthy skin, usually yellow, with fœtid breath. Such being the case, it is the duty of the judicious medical man to ascertain the causes of this torpor, and, if possible, to remove it. If the

* Yeldham on Acute Diseases. 1870.

diet or habits be faulty, to correct it; and, this failing, then to give suitable drugs. Against interference, it has been urged that many persons will pass days or weeks without relief, and yet retain health; to which it may be replied, that these cases are exceptions; that, as a rule, health is alone possessed by the individual who obeys the laws of nature, and defæcates at least once a day. So important is this to the well being of the individual, whether young or old, that its omission is, as a rule, followed by functional disturbance, and, if continued, by actual disease. And this fact cannot be too much impressed on all persons. Hence, the management of the bowels in early life should be well understood by mothers; so, too, their proper regulation in the middle periods of life; and the care of these organs should be well regarded in the decline of life—not so much by physic as by the laws of common sense. Here the value of enemata may be spoken of—they simply empty an over-loaded rectum.

Of the evils of purgatives, Dr, Carr dwelt with much force, contrasting the practice of the present day, which goes in for gentle rather than strong remedies, with that of thirty years ago. No form of cathartic can do good over and above the removing from the prima via its contents, and the exciting the exhalents to pour out of the blood its serum. Purgation must be, after the removal of the excreta, a weakening process, and should never be practised in cases of atonic disease, or where there is a condition of shock. In the parturient state, it is always a good rule to pass three or four days without relief, after which, if there be no action, to give at bedtime a teaspoonful of castor oil.

Aperients should seldom be given in known, or suspected, malignant disease of the abdominal viscera. In these cases, opium combined with belladonna, will give the needful relief. A similar treatment, Dr. Carr always practices in cases of acute torpor with urgent symptoms of constipation, severe abdominal pain, and sickness, with a high temperature; repeated doses of opium with belladonna, and continued for a few days, usually succeed in obtaining the desired alvine evacuation.

In persons whose powers are feeble, and who eat both little and light food, the daily relief may be, as pointed out by Sir Henry Holland, too much. An action on alternate days, in their peculiar circumstances, is far better; still with them it is very undesirable to permit the bowels to get over loaded.

It will thus be seen that, as a rule, health is maintained by obtaining a daily relief; that diet and good habits favour this; that, failing the good rule, gentle medicines will establish it; and that strong purgatives should be rarely resorted to.

An animated discussion followed, in which the President, Drs. Gooding, Thorowgood, Lockhart, Purvis, Creed, &c., took part; after which, a vote of thanks was passed to the essayist.

The Dublin Obstetrical Society held the first meeting of its Thirty-third Session on the 26th ult.

The Report presented by the Council represented the Society to be in a flourishing condition, and advised that the President should be eligible to re-election, and should hold office for two years.

Dr. Rigland, in moving the adoption of the Report, said, that he regarded with approval the proposition that the President should act for two years, especially as the gentleman who would first experience the operation of the rule would be their former valued secretary, Dr. Kidd.

Dr. Darby, of Bray, seconded the motion.

Dr. George Johnson, Master of the Rotundo Hospital, in delivering the Inaugural Address, reviewed the progress of the Society, and the communications which had been made to it during its last session.

The President then announced that Dr. Kidd had been elected President, who thereupon assumed the chair, and returned thanks for the honour.

Dr. Sawyer moved the thanks of the Society to the ex-president, which was seconded by Dr. More Madden.

The President then announced that Drs. Byrne and H. Kennedy had been elected Vice-presidents, and Drs. Beatty, Churchilll, Denham, McClintock, and Roe as Council.

Dr. Churchill proposed, and Dr. Corrigan seconded the vote of thanks of the Society to the Presidents of the Colleges of Physicians and Surgeons, which was responded to by Drs. Banks and Walsh.

The President of the College of Surgeons alluded to the connection which his College was proud to acknowledge with the Society.

SUGGESTIONS OF THE CONFERENCE OF IRISH LICENSING BODIES, AS TO MEDICAL LEGISLATION.

A conference was held of Representatives appointed by the Board of Trinity College, Dublin, the Senate of the Queen's University, the King and Queen's College of Physicians, and the Royal College of Surgeons in Ireland; in accordance with the following Resolution passed by the College of Physicians, on 7th October, 1870:—

"That it appears desirable, in regard to the probability of approaching legislation on Medical matters, that a Conference should be held of the several Universities and other Corporate Bodies in Ireland, authorized to grant Degrees or Licenses in Medicine or Surgery, with the object, if possible, of laying down principles or views as the united opinions of those several Bodies."

The Representatives named by the respective Bodies were—*University of Dublin*:—Andrew Searle Hart, LL.D; William Stokes, M.D; James Apjohn, M.D.; *Queen's University*:—Sir Dominic J. Corrigan, Bart., M.D., M.P; Sir Robert Kane, M.D; William M'Cormac, M.D; *King and Queen's College of Physicians*:—John Banks, M.D., President; Thomas Edward Beatty, M.D; Rev. Samuel Haughton, M.D; *Royal College of Surgeons*:—Albert J. Walsh, M.D., President; James Henry Wharton, M.B., Vice-President; Rawdon Macnamara, M.D.

The following Suggestions were agreed to at the Conference, to be submitted for the consideration of the respective Bodies:—

Suggestion I.

That the privilege of granting Degrees or Licenses in Medicine or Surgery, as at present possessed under Law or Charter by the several Universities and Medical or Surgical Corporations, should not be interfered with.

Suggestion II.

That this Conference does not oppose the establishment of a General Medical Examining Board, whose Certificate shall be indispensable for Registration.

Suggestion III.

That the holders of Degrees or Licenses in Medicine and Surgery, granted by any one or more of the Universities, or Medical or Surgical Corporations, empowered by Law or Charter to grant such, should be entitled to present themselves for Examination before the General Medical Examining Board, on production of such Degrees or Licenses.

Suggestion IV.

That no Candidate should be admitted to the Examination of such General Medical Board, who does not previously possess a Medical and Surgical Qualification from one or more of the Corporations legally entitled to grant the same.

Suggestion V.

That the General Medical Examining Board should consist of an equal number of members from England, Ireland, and Scotland; and that the Meetings for Examination should be held successively in England, Ireland, and Scotland, by all the members of the Board, or such as may be deemed requisite from time to time, provided always that each Division of the United Kingdom shall be represented at each Examination.

Suggestion VI.

That the General Medical Examining Board should not have any power to interfere with the General or Professional

Education of Candidates; that the regulation of the curriculum of education should remain with the several Universities and Colleges, as at present; the functions of the General Examining Board being altogether confined to the principle and details of Examination.

Suggestion VII.

That Candidates should not be put to any expense in undergoing the Examination of the General Examining Board; that such Examination, being for the advantage and protection of the public, the State should defray the expenses, in like manner as the expenses of Examination for the Army and Navy are paid by the State.

Suggestion VIII.

That the Examiners from each Division of the Kingdom should be elected by the Universities and Medical Corporations entitled by Law or Charter to grant Degrees or Licenses in Medicine or Surgery, in such division of the Kingdom.

Suggestion IX.

That the General Medical Examining Board, so elected, should be empowered and required to draw up a Scheme for the Examination, both in general and professional knowledge, of all Candidates entitled to present themselves; such Scheme of Examination to be subject to the approval of the General Medical Council. Signed,

J. T. Banks, *Chairman.*

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 7, 1870.

PHARMACY IN IRELAND.

The Bill for the Regulation of Pharmacy in Ireland, put forth by the Irish Apothecaries' Company, and published *in extenso* in the Medical Press and Circular the week before last, would seem to be the forlorn hope of the Company to maintain intact its privileges as a licensing body, challenged on one side by the College of Physicians, and on the other by the pharmacists of Ireland. We have no anticipation that the compromise to which the Apothecaries' Company asks the adhesion of the Licensing Bodies and the Chemists will ever become law, and it would be very unfortunate for the future of Irish pharmacy that it should.

The Apothecaries' Company has, in spite of every warning, lost its footing on Pharmaceutical ground, and it has utterly failed to establish itself on a Medical standpoint, and the weakness of its foothold has made it the subject of allied attack. The College of Physicians, on the one side, has taken vigorous action to have annulled the meagre title to grant licenses in Medicine, in maintaining which the Company has almost spent its last breath, and the public, in refusing the license proferred to them by the Company, has *de facto* effected that which the College of Physicians desires to complete. The Medical qualifying power has already slipped from the hands of the Company, and it only remains for Parliament or the Medical Council formally to take away the semblance of the much-desired reality. But while the College of Physicians is pressing the Company hotly in the effort to force it back upon its pharmaceutical functions, the Chemists of Ireland are contesting the possession of those functions with much vigour and with the prestige of recent success in England.

The English Pharmacy Act has been but a short time in operation, and already its provisions have effected so good an object that the Irish Chemists are ardent in the desire to have the practice of Pharmacy amongst them regulated on some more definite principle, and directed by some more nervous hand than that of the Apothecaries' Company.

Beset thus in front and rear, and abandoned by its public patrons, the Apothecaries' Company has wisely set itself to do without violence to its own prejudices that which others threaten to carry out by summarily sweeping it out of the way.

The Bill promoted by the Company creates a Pharmaceutical Society of Ireland to be composed of all registered chemists and licensed apothecaries. It vests in this Society the making of "all bye-laws and rules for the advancement of pharmacy," and creates by an equal contingent from the Company and the Society an Examining Board before whom every Chemist must pass before he can practise Pharmacy. The machinery of registration and the penalty for practising without that qualification are substantially the same as those provided by the Medical Act.

We epitomise some points of interest in the clauses. Clause 1 forbids any person other than a duly-qualified Apothecary or a Registered Pharmaceutical Chemist "to "sell or to keep open shop for retailing, dispensing, or "compounding medical prescriptions in Ireland." Clause 4 authorises and requires the Examiners to examine candidates "in their knowledge of the Latin and English "languages, in Arithmetic, in Botany, in Materia Medica, "in Pharmaceutical and General Chemistry, in Practical "Pharmacy, in the British Pharmacopœia, and such other "subjects as may be determined on." "Provided always "that such examinations shall not include the Theory and "Practice of Medicine, Surgery, or Midwifery, or any "branch of Medicine or Surgery."

Clause 6 fixes the fees at the following rate:—

Apprentices and Students . .	2 guineas.
Assistants	2 „
Pharmaceutical Chemists . .	5 „
Registration	5 shillings.

Clause 13 provides that *any person* other than a Registered Chemist or Apothecary, "who shall keep an open "shop or wareroom for the retailing, dispensing, or com- "pounding of medical prescriptions," or who shall use any title implying that he is a qualified Apothecary or Registered Chemist. "And any Apothecary or Chemist who

shall take a Student, Apprentice, or Assistant, shall be liable to a penalty of £5.

Clause 14 declares that registration under the Act shall not entitle any person to practise Medicine or Surgery, or any branch of Medicine or Surgery.

Clause 15 enables the Examiners to grant Registration to all existing Chemists and Druggists who have been in business for five years on an examination "as to his know-"ledge, skill, and competency to carry on and conduct the "business of a Pharmaceutical Chemist."

Our analysis of the Bill shows us, therefore, that its object is one which the Profession in Ireland cannot approve. By it the Apothecaries' Company alienates for ever its pharmaceutical functions, and elects to confine itself *en permanence* to the work of giving Medical qualifications and selling drugs, and it is the duty of those who have in charge the education and qualification of our Profession to see that that object is defeated. Whether the Pharmaceutical guardianship of Ireland is in the hands of the Apothecaries' Company or the Pharmacentical Society is not material to Medical men so long as the function is well discharged, but the Profession cannot connive at the transfer of such important functions to an untried body.

The infatuation which has induced the Apothecaries' Company to promulgate this measure is inconceivable. The field of Irish Pharmacy is yet open to them, and if they were ready to accept its cultivation as a duty, the agitation for a Pharmaceutical Society would at once cease to exist, and the co-operation of the Medical authorities would be secured to them. Casting aside this *rôle* under which they might, without doubt, achieve influence and riches, they choose rather to pursue an *ignis fatuus* which has already slipped from their grasp, and which, if they could ever hope to seize it, would not be worth holding. We appeal to the Governors to abandon this foolish and vain self-deception, to abandon a pursuit in which they have left behind alike income and influence, and to take up and wield with energy and effect the instruments which the empire placed in their hands, but which they have allowed to rust in wilful disuse.

Notes on Current Topics.

About the War and Wounded

Those who believe that Germans cannot be brutalized, should read the correspondence of the *Daily News*. That paper sides strongly with Prussia as do its correspondents. Yet these gentlemen throw a strong light on the horrors of war. The other day there was an account of the cruelties of the Bavarians, under the Grand Duke of Mecklenburgh, which shows how fiendish men can be made by war.

***

Another correspondent states, that for the week ending 5th November, the mortality of Paris had risen to 1,800, and the fatal small-pox cases to 380; in the next week, the total mortality was 1,900, and by small-pox 419. There are a great many deaths from gastric complaints, a consequence of the prices of the necessaries of life. Paris was maintaining a death-rate from 300 to 400 in excess of that of London.

***

Eleven weeke have elapsed since the Registrar-General began to note in his Weekly Return the non-arrival of the mortality returns from Paris which he had been in the habit previously of receiving from the Paris authorities and publishing weekly. Before the investment of the city, the deaths were averaging about 1,200 weekly. Small-pox, which had caused earlier in the year from 200 to 300 deaths weekly, had subsided to a weekly average, in August and September, of 100 to 200 deaths.

***

From some official statistics lately published in the *Pall Mall Gazette*, it appears that Paris possesses some exceptional advantages which may prolong its resistance. The adults of Paris capable of work, amount to nearly three-fourths of the whole population. On comparing London with Paris, the former city has 61, the latter 71 per cent. of population at the working age, fifteen to sixty. The *Pall Mall Gazette* says, that the importance of this fact is undeniable, and adds that the proportion of medical men to the population of Paris is almost identical with that of London.

***

The Special Correspondent of the *Daily News* at Amiens gives an account of the neglect of the wounded, which is a sad disgrace to that rich city. While the wealthy of the place eat as usual, hundreds of brave fellows who had fought for them lay untended on the battle field. Happily, the provision of the English National Society had done much. But for the English ambulance, we are told, 1,000 wounded would have perished like dogs, without one effort to supply them with a single comfort. The English Society's doctors—Leslie and Goodenough—were for days the only gentlemen whose professional services were available, and, says the correspondent, I believe it is to the exertions of this Society that some hundreds of these poor Frenchmen have been rescued from death. A few civilian doctors arrived in course of time from Amiens, and some military medical gentlemen turned up, but instead of setting to work they commenced a quarrel on the point of etiquette. The Jews would have no dealings with the Samaritans. Meantime, there lay hundreds of men on the cold floors, nothing in the way of bedding or bed clothes, lying as they were placed days previously when carried off the "field, and no aid, except the English Society's united stores supplied."

***

The relief of the French peasants by the fund which Mr. W. H. Bullock has so nobly administered, and which exceeds £10,500, is one of the brightest acts of charity developed by the horrors of the war. We regret to say that the life of one of Mr. Bullock's ablest professional coadjutors has been sacrificed to the toils he underwent. He is another noble martyr in the cause of humanity, of which our Profession may well be proud. Mr. Bullock, in a letter dated Sedan, November 30, and published in London on Monday, thus writes of him—"I grieve to have to report the death of Dr. Davis, the coloured physician, which took place on Sunday last, November 27, at Pont Mangy, where he was devoting himself to every kind of good work for the benefit of the poor operatives and peasantry of the surrounding villages.

The Marriage of Soldiers *v.* Syphilis.

A correspondent of the *Times* says "If the opponents of the Contagious Diseases Acts would direct their efforts to an increase in the number of married soldiers, they

would do more to remove the causes of disease than by any other means. A regiment, when on Indian or foreign service, is allowed a limit of 12 per cent. of married men, but even this increase on the home limit is so applied that, most regiments leave England without so many married men, and wives are not to be got in India. It is simply a scandalous fact, that in 1866, of 51,578 rank and file in all India, only 4,210 were married, or 8·11 per cent. What is the result? The daily sick rate of the unmarried is more than double that of the married men, due no doubt in great measure to venereal disease. If all the army were allowed to marry to-morrow not half the men would avail themselves of the permission. Let the experiment be tried to the extent of one-fourth, and let every corps leaving England, be allowed to marry up to that limit, and we shall gradually see the root of the evil removed. Of course soldiers' wives and children die in India, and they are expensive, and in war they are impedimenta. But the new barracks will reduce the mortality, and no one, save a military martinet, can hesitate as to which course is the least evil."

Teaching of Dental Surgery in America.

THE Correspondent of the *Times* at Philadelphia, writes as follows of the American Schools of Dental Surgery :— While Americans of culture to finish their education usually go to the Universities of Europe, in the speciality of dentistry the current is reversed, the graduates of the highest medical schools abroad coming to the United States, and chiefly to Philadelphia, to finish their dental education. There are in the United States nine dental schools, two being in Philadelphia, two at Boston, and one each at New York, New Orleans, Baltimore, St. Louis, and Cincinnati. Two-thirds of all the students attend the two colleges in this city, of which the "Philadelphia Dental College" is the chief, and it is noticed that about one-fourth of the students at this college are generally from abroad, nearly every country in Europe being represented. Of the high distinction of having graduates from the Universities of London, Vienna, and Berlin come here to finish their dental education the Philadelphians are quite proud, as they also are of the fact that their city contains the most extensive manufactory of dental instruments and artificial teeth in this country, if not in the world.

An Outbreak of Fever in England.

AN outbreak of typhoid fever has occurred at Stevington, and is, we believe, engaging the attention of the Medical Department of the Privy Council. From a report by Dr. Price, of Bedford, it appears that, of a population of from 600 to 700, at least 170 have already suffered from the disease. Its importation has been traced and its course from house to house ; its peculiar and known mode of propagation is illustrated from instances in which families of six and nine have contracted the disease, not from the simultaneous action of a virulent epidemic poison, but successively by the conveyance of the poison from one to another, and its perpetuation in soil and water. The conditions of life at Stevington are favourable for such a course. In one house were found six men lodgers sleeping on the floor in a low room twelve feet square ; they had to pass through a room where a young woman lay ill, and died of the fever ; and one at least of the lodgers (navvies) took the disease. The whole family of men above mentioned, who all took the disease, slept in a space which gave about 1,150 cubic feet of air. The amended regulations of the Poor-law Board for workhouses would allow them a *minimum* of about 5,000 feet in health. and of about 9,000 in illness.

Matriculations at the University of Edinburgh.

THE number of students matriculated in the present session of Edinburgh University up to this date in the various Faculties is greater than in any year since 1832. Including the summer session, the number matriculated is 1,732.

London Hospital for Incurables.

THE sixteenth annual meeting of this institution was held at the London Tavern, on Friday afternoon, The report stated that the receipts of 1869 and 1870 exceeded those of any former year. The investment fund owing to heavy expenses attendant upon building, showed a deficiency of £7,069 5s. After consideration the Board decided to reduce the rate of election. The balance due to investments stood at £1,044 5s. being a reduction of £6,025. The Board, while expending directly upon the beneficiaries £12,800 a-year, were able to add to the reserve fund.

Thymol.

MR. HENRY DRAPER, of Dublin, exhibited to the Dublin Chemical Club at its last meeting, a specimen of a new preparation which has been proposed as a substitute for carbolic acid. It is named thymol, and is a derivative of the Thymus vulgaris, the monarda or horse-mint, and the Ptychotisan East Indian umbelliferous plant. It is of a similar chemical composition to carbolic acid, but destitute of the very unpleasant smell of this popular disinfectant. It melts at 44° Centigrade, and is soluble in 300 parts of water It resembles carbolic acid in forming compounds with potash and soda, but differs from it in that these compounds are very unstable, being decomposed even by carbonic acid.

The introduction of this preparation recalls to mind the fact, that oil of thyme was in past years a favourite popular remedy for the toothache, and it is only now that its efficacy and the causes of such efficacy have been made manifest. Last year one of our foreign correspondents drew attention to this agent in a very interesting letter.

The oil of thyme is prepared in large quantities in the South of France, where it is used for printing on china.

Ozokerit.

THE mineral, ozokerit, the celebrity of which has been achieved, it is said, by an expenditure in advertising of something approaching £15,000 by Messrs. Field, of London, was exhibited by Mr. Henry Draper, at the last meeting of the Dublin Chemical Club.

This substance is found overlying the coal measures in Moldavia, Austria, and at the Urpeth Colliery, at Newcastle-on-Tyne. It is purified by distillation, and afterwards by pressing it and treating it with sulphuric acid, and when purified has an extremely high melting point. For this characteristic, which has not been

found in any other similar substances except wax, it is selected for the manufacture of candles, because it affords a larger wick and a better illuminating power at a lower price. From Mr. Draper's experiments, it appears that pure ozokerit and white wax melt at 150° F., the candle as sold at 138°, paraffin at 129°. There is, therefore an admixture with it of some other material.

Even the residue of ozokerit after its purification has been utilised. The late Dr. Mathiesson, whose untimely death by his own hand is still in our memory, patented it as an insulator for telegraphic wires, for which purpose it is said to be eminently suitable.

Small-pox in London.

THE wards of the Small-pox Hospital, it appears, are crowded at present, and some patients are sent away who apply for admission. This is a very rare occurrence indeed, and suggests the fact that our foolish fellow-citizens of the Anti-vaccination League have persuaded many of their poorer neighbours to neglect the vaccination of their children, and re-vaccination of themselves. On Saturday at the Asylum Board, Dr. Brewer in the chair, it was stated that a temporary hospital for small-pox had been opened at Hampstead. The number of cases at first 90 had increased to 120. Dr. Bridges the Poor-law Inspector, said there were now 308 cases among the paupers of London.

Medical Will Making.

A VERY scathing rebuke was administered last week by the judges of the Dublin Probate Court to a medical practitioner of a provincial town, in reference to the part taken by him in the concoction of a will.

The gentleman in question had been in attendance on the testatrix. At the bidding of the local priest he attended on the night of the testatrix's death to witness the will, which it is unnecessary to say, conveyed the testator's property almost entirely to the church to which the priest belonged. Although as admitted by himself the testatrix was absolutely unconscious and all but dead, the medical man, by holding her hand, made a mark which he considered equivalent to a signature of the will and attested the document, and the fact that it had been only read by or to the testatrix. Under the circumstances, the judges, of course, unanimously set aside the will, and emphatically condemned the actors in the matter. We cannot hesitate to endorse that censure. It would be a great calamity for our profession if the public should derive the impression that advantage may be taken by their physician of their dying confidence for such a purpose.

We are distressed and astonished to learn that a medical gentleman, whom we know to be justly respected, could yield to an order or inducement, to lend himself to so scandalous a transaction. Clerical will making is, unhappily, no new disgrace to those who practice it; medical will making is fortunately not yet habitual, and we earnestly trust that it will never be so.

Cancer.

MR. HAVILAND says that, geologically, the hardest and most elevated rocks are the sites where the least mortality from cancer is found. Along the river courses which flood their banks seasonally, such as the Thames, the Severn, the Mid-Devon, and Yorkshire rivers, are to be found the districts in which the highest mortality takes place: and that whereon from the nature of the rocks forming the water-shed, the floods are much discoloured by alluvium, and where, from the flatness of the country, the floods are retained and not easily drained off, there we fiud the greatest mortality from cancer among females.

Dr. Protheroe Smith's Exhausting Needle-Trocar.

DR. P. SMITH adapts needle trocars to an exhausting air-pump or glass syringe, and thus evacuates the contents of effusions into the joints, pleura, &c. He even uses the plan for cases of tympanitic distension. He has, on one occasion, he affirms, withdrawn sixteen pints in less than half-an-hour from an ascitic abdomen. Mayer and Meltzer, of London, manufacture this instrument.

Dr. Robert Knox.

DR. LONSDALE has just brought out a life of Robert KNOX, the once famous lecturer on anatomy of Edinburgh. From this interesting biography, it seems that the terrible affair of Burke and Hare in 1828 proved the ruin of this distinguished teacher's fame in Edinburgh, and that he died comparatively unknown and poor in Hackney parish, London. One of his last works which has been much admired by some is the "Races of Man."

Mr. Langley on Poverty.

DR. BAXTER LANGLEY, speaking at Manchester, on the subject of the Contagious Diseases Acts, is reported in the *Shield* to have said that, "Poverty was the great cause of prostitution. They saw around them a population of which one part was extremely rich, and the other part dreadfully poor. When the agitation against the Contagious Diseases Acts had achieved its purposes, they would have to look to these broader and deeper issues, and consider whether something could not be done to modify the condition of at least one of these two classes of society. If you could so amend the conditions of Society that every man could obtain a fair day's work, and a fair day's wage for it, if you could place your young men in such a position that they could create a home, and cultivate family ties, you would have laid the axe at the root of the upas tree, which blossoms with prostitution."

The Next Naval Examination.

IT is announced that an Examination of Candidates for appointment as Assistant Surgeons in the Royal Navy will be held in London in the course of February next, and of which further particulars, as to date, &c., will be duly announced.

The Proposed New Regulations for Examinations in the Royal College of Surgeons of Ireland.

THE Council of the Irish College has not yet concluded its consideration of the proposed alterations in its examination system. The publication by the *Lancet* of the details of a part of that scheme is, therefore, premature, and unauthorised, and the statement that it will not come into operation for a year is entirely devoid of foundation.

The Irish Poor-Law Unions Apothecary.

THE qualification required by the Poor-law Commissioners for the contemplated office of Poor-law Unions Apothecary is likely, it seems, to secure the election of the "square" man for the "round" hole.

The Commissioners have required only that the candidate shall be a Licentiate-Apothecary, and it is unnecessary for us to tell those who know how much knowledge of drugs is requisite for that qualification, how little chance there is that an efficient officer will be found within the body of Apothecaries. It may be stated, as a general principle, that in Ireland no apothecary knows anything about the purity or prices of drugs—and no one who knows anything about the purity or prices of drugs is an apothecary. Sir William Carroll, ex-Lord Mayor of Dublin, a genial and hospitable member of the Corporation, who about twenty years ago dispensed prescriptions, and since then has been happily relieved of any such precarious occupation, is the best known candidate. His modest claim must speak for itself. His election address says :—

"I am thoroughly and practically conversant with the nature and qualities of every description of Medicines and Medical and Surgical Appliances. I am practically familiar with the detection, analytically and otherwise, of all adulterations and impurities. I know the best markets for the purchase of Medicines ; and last, and not least, I have great experience in all Pharmaceutical operations."

With "whispering humbleness" we confess to being for the first time aware that Sir William Carroll's pleasant exterior included all these virtues, and with characteristic scepticism we suggest a competitive examination.

But what boots the question of special knowledge ! Sir William Carroll is impressed with the hall mark, beyond which no elector dare go. His religion and politics are *de rigueur*, and surely they will be potent to secure good and cheap medicines to poor Paddy Murphy, the dispensary "red ticket" at Ballysloughguttery.

Already, the fatal policy of putting the appointment in the hands of guardians is bearing its fruit. There are 163 Unions, and we expect, at least, 60 different persons to be chosen by the Irish Guardians. Here are a few of the reputed candidates—Sir William Carroll and three governors of the Apothecaries' Hall ; Dr. Tucker, Sligo ; Dr. Raverty, Bray ; Dr. Byrn, New Ross ; Dr. Hayes, Naas ; Mr. Oldham, of Dublin ; Dr. England, of Galway ; Dr. —, but no ! Our space fails us ; perhaps next week we may add an extra sheet, and hope the space may be sufficient.

The Chance of the Corporations.

WE last week examined, in a leading article, a new Medical Bill. Here we are desirous of recalling to our readers an article on the "Chance of the Corporations," that appeared in our columns a few months ago, and which elicited many expressions of approval. That article pointed out how easy it would be for the medical authorities in the three kingdoms severally to amalgamate or combine *voluntarily*, and thus effect all that was proposed by the Government Bill last year.

Negotiations are now going on, both in England and Ireland, with a view to accomplish this, and it is just possible they may be successful. In that case the Bill proposed by the *Lancet* would be as useless as the one lost last year. Everything of any value proposed in either, would be carried out by voluntary agreement, This would be better than compulsion, and, who knows, when once union were found to be successful, it might make such progress, that after all the Profession would become a united fraternity, and the medical authorities no longer divided by jealous rivalries. It seems Utopian, but the Irish authorities seem going the right way to work.

Method and Medicine.

UNDER this title, Dr. Balthazar Foster, of Birmingham, has recently published a remarkable essay on "The History of the Development of Medicine as a Science." The essay originally appeared in a volume, entitled "Essays by Members of the Birmingham Speculative Club." This volume, which contained six other essays, has been so well received and noticed by the London and provincial press, that two months have sufficed to see it out of print. Dr. Foster's essay is now about to appear in a separate form, and we commend it to all interested in the scientific progress of medicine.

Organization of Military Hospitals.

THE *United Service Gazette* announces that the Committee appointed some time since to consider this subject have presented their report. It is rather difficult, from the way in which the report is worded, to arrive at the intentions of the Committee or their suggestions. It is recommended that the Regimental Hospital system shall, to a great extent, be broken up, and that the present complete organization which permits a regiment to have its distinct surgery and special hospital attendants, told off from its own ranks, shall cease to exist. The sick will, therefore, have to be transported from one district hospital to another. They also suggest that the regimental medical officers shall not attend exclusively upon their own patients, but be at the disposal of the senior officer of their department in the district hospital.

Poison in Snuff.

DR. GARROD lately lectured at King's College on a case of lead-poisoning in which the mineral was taken in snuff. It was rappee that the patient habitually took, and the damp snuff packed in the usual lead cases converted some into carbonate. The symptoms were serious, and with difficulty traced to their real source. Then several packages were purchased and found to be contaminated with the poison. Snuff-takers would do well to take this lesson to heart, and the profession is hereby reminded of the subtle manner in which lead is apt to be conveyed into the system where in time it is sure to give rise to its injurious effects.

Report of the Alice Hospital at Darmstadt.

ON the 10th of November, Her Royal Highness the Princess Louis of Hesse was at the hospital and repeated her visit on the 11th.

Dr. Mayo had the honour of dining with the Queen of Prussia at the palace, Homburg on the 10th instant. Her Majesty expressed the greatest interest in all the arrangements of the Alice Hospital, and regretted that indisposition had prevented her from visiting it during her stay at Homburg.

Staff-Surgeon Fitzgerald of the Medical Department of the British War Office paid an official visit to the hospital on the 12th instant, and examined all its arrangements minutely.

A supply of stores consisting of 69 bales and boxes was received from the National Society for aid to the Sick and Wounded on the 12th and 13th ; and a present of 13 large packages from Manchester for the Manchester ward, on the following day.

Dr. Mayo was informed on the 15th by Ministerialrath von Preuschen, of tthe Hessian War Office, that in pursuance of instructions from Berlin it was proposed to increase it, by adding wards for 120 more beds, the cost to be defrayed by the Government. As the kitchen and offices had been prepared with a view to the possibility of increased numbers, Dr. Mayo accepted the proposal without hesitation.

H.R.H. the Princess Louis of Hesse again came to the hospital on the 16th inst., and expressed her satisfaction at its projected enlargement.

A further subsidy of £1,000 has been received from the National Society, together with a very kind letter from Colonel Lindsay.

Medical Reform.

The *Lancet* devotes another article to the exposition of its Bill in which it acknowledges that our criticisms of last week were "fair and friendly," and endeavours to remove the effect of some of them and to show the advance that would be made by the Bill. We trust the criticisms of the Medical Press will always be marked by fairness, and we have always been anxious to adopt a "friendly" tone whenever a great question demanded the union of all interested in it. We never hesitate to condemn what seems to us wrong in any one of our contemporaries, but we hope always to be as ready to give credit when due. As to the size of the Council we wish to explain that our objection to reduce it is not merely the work to be got through. We thought we made it clear that we could not think the existing number too large to represent all the interests involved. Another important point is, the practicability of carrying any measure. Will it be so easy to snuff out the corporations in the manner proposed? We almost fancy the more logical and more radical plan of Mr. Charles Hawkins would be quite as easy to accomplish, and it really has the merit of being more thorough and complete. There are a good many other points touched upon which all reformers are as one. The fact is, the existing system has only been endurable because the men who administer it are, as a body, unexceptionable. The same may be said as to the General Medical Council. It is not the individuals to whom objection is made. The fault lies in the constitution of the Council. We wish our contemporary would look over our last week's article again. There are many points in that, we think, deserve full consideration. We may especially mention the question of one portal or three. Others will suggest themselves to any reader as those which our contemporary should particularly consider.

Dr. Loughi is translating Professor Erichsen's standard work on Surgery, into Italian.

The Appeal of Sir Patrick Dun's Hospital.

Appeals for public charity are unfortunately the normal condition of hospitals, and they are so deserving of aid and assistance from those who know, as we do, their claims to attention and response, that it is an unpleasant duty for us to find fault with their form or substance. An advertisement lately issued by the Governors of Sir Patrick Dun's Hospital, and signed by the President of the College of Physicians in Ireland, appears, however, to require some observation.

Sir Patrick Dun's is an institution as deserving of public generosity as the rest of the Dublin Hospitals, and it is quite unnecessary for its administration, in appealing for help, to resort to clap-trap or to attempt to climb into popularity on the shoulders of other hospitals or their medical officers.

The Governors claim credit and support for the institution, on the grounds that, "from its foundation, Sir Patrick Dun's Hospital has been administered *solely for the benefit of the poor* and the purchase of its hospital appointments is rendered impossible by Act of Parliament, its medical officers being selected *on the grounds of merit and fitness only*."

This statement conveys a false and unkind inuendo respecting other institutions. It is perfectly untrue to suggest that the Dublin Hospitals are administered for any other purpose than the benefit of the poor, in any greater degree than is Sir Patrick Dun's itself, and it is also untrue that merit and fitness receive less consideration in the selection of medical officers in other hospitals than in it.

Still less does Sir Patrick Dun's require to employ the following ludicrous specimen of "claptrap" in its appeal for charity :—

"During the cholera visitation of 1866, a gift of seven half-pence was made to the hospital by a child of a very poor man whose life was saved in the hospital. This donation, which was highly prized, was expended in the purchase of a cheap doll to amuse a child suffering from hip-joint disease."

It is not complimentary to the benevolent citizens of Dublin, to suppose that the disinterment of the child's doll of 1866, is the sort of stuff which will stimulate their compassion. A conparison of the sums spent annually on salaries and establishment charges, and on the direct relief of the sick poor, would be more convincing than any quantity of such puerility, and if the Governors are not prepared to make such a statement public, the less they say about the "benefit of the poor and merit and fitness" the better.

New Books in Medicine, Surgery, and Science.

(*Continued from page* 425.)

The following books referring to Medicine, Surgery, and the Collateral Sciences, will appear within the forthcoming Session :—

A Fourth Edition of Yarrell's British Birds. Edited by Professor Alfred Newton.

Dr. Bevan on the Honey Bee. Revised Edition. By W. Augustus Munn.

Beeton's Dictionary of Natural History. A Compendious Cyclopædia of the Animal Kingdom.

Man, in the Past, Present, and Future. A Popular Account of the Results of the Recent Scientific Research as regards the Origin, Position, and Prospects of the Human Race, from the German of Dr. L. Buchner. By W. S. Daly, Assistant-Sec. Geological Society, London. &c.

New Edition of Jukes's Manual of Geology. Edited by Archibald Geikie, F.G.S., &c.

Introductory Text-book of Meteorology, for the Use of Schools and Private Students. By Alexander Buchan, M.A., F.R.S.E.

The Heavens. By Amedée Guillemin. Edited by J. Norman Lockyer, F.R.A.S. New Edition.

The Earth, being a Descriptive History of the Phenomena and the Life of the Globe.

Geology. By E. Phillips, M.A., F.R.S., Professor of Geology, Oxford.

Spectrum Analysis, familiarly explained by Dr. H. Schellen. Translated from the German. Edited with Notes, by William Huggins.

The Sun. By Richard A. Proctor, B.A., F.R.A.S.

The Sun. By Balfour Stewart, LL.D., F.R.S., and J. Norman Lockyer, F.R.S.

A Treatise on Magnetism. By G. B. Airy, Astronomer Royal.

A Dictionary of Science. Edited by G. Farrer Rodwell. The Haydn Series.

The Metallurgy of Gold, Silver, and Mercury. By John Percy, M.D., F.R.S.

Admiralty Manual of Scientific Enquiry. Edited by Sir J. F. Herschel and Robert Main, M.A.

The Student's Elements of Geology. By Sir Charles Lyell, Bart., F.R.S.

Handbook of Physics. By William Rossiter, F.R.A.S.

The Essentials of Geometry, Plane and Solid. By J. R. Morrell, formerly Inspector of Schools.

Elementary Lessons in Physics. By Balfour Stewart, LL.D., F.R.S.

Key to Algebra, for Colleges and Schools. By I. Todhunter, M.A., F.R.S.

Amory, R., Experiments upon the Physiological Action of Bromide of Potassium and Ammonium (as determined on Man and Lower Animals).

Barclay, A. W., Manual of Medical Diagnosis. 3rd edit.

Duncan, J. Matthews, On the Mortality of Child-bed, and Maternity Hospitals.

Fergusson, Sir William, A System of Practical Surgery. 5th edit.

Foote, E. B., Plain Home Talk about the Human System.

Gee, Samuel, Auscultation and Percussion, together with the other Methods of Physical Examination of the Chest.

Hill, Berkeley, Treatment of the Sick and Wounded. Illustrated by Observations made at the Seat of War.

Hutchison, J. C., A Treatise on Physiology and Hygiene, for Educational Institutions and General Readers.

Moffit, A Staff Surgeon, A Manual of Instruction for Attendants on Sick and Wounded in War.

Moynier and Appia, MM., Help for Sick and Wounded. Translated by John Furley.

Myer, Arthur B. R., On the Etiology and Prevalence of Diseases of the Heart among Soldiers; The "Alexander" Prize Essay.

Ward, T., First Grade in Inorganic Chemistry.

Storer, F. A., A Cyclopædia of Quantitative Chemical Analysis.

Snelling, T. G., Relaxation of the Pelvic Symphyses during Pregnancy and Parturition.

Baird, S. F., Cassi, J., and Lawrence, G. M., The Birds of North America. With an Atlas of 100 Plates. 2 vols. Royal 4to, pp. lvi.

Lunatic Asylums (Ireland). 19th Annual Report. 8vo.

Public Health. 12th Annual Report. 8vo.

Prisons (Ireland). 48th Annual Report. 8vo.

Workshops Regulation Act, Return relating to.

Berwick, George, The Forces of the Universe.

Flower, W. H., Osteology of the Mammalia.

Freeman, A., Solar Fictions: Inquiry into the Received Astronomical Doctrines and Popular Opinions concerning the Sun.

Ponton, Mungo, Earthquakes and Volcanoes.

Yellow Fever has effected a footing on Governor Island, near New York.

The old Birmingham students are to dine together on the 8th inst.

A capital set of baths for the treatment of skin diseases is about to be erected at University College Hospital.

Professor John Gamgee thinks the new disinfectant chloralum will be very useful in purifying dairy utensils.

Dr. Parkes and Count Dr. Wollowicz have presented to the Royal Society some experiments with claret in continuation of their former paper on alcohol.

Boarding-out pauper children seems to be growing in public favour. We have, in all directions, heard of its success—nowhere of its failure.

Mr. Canden, of Worcester, is to preside at the next annual dinner of Fellows of the Royal College of Surgeons of England.

The Dublin Pathological Society has announced that the subject for its prize medal for the ensuing year wil be "The Diseases and Injuries of the Spinal Cord."

The profession will have learned with much regret of Sir R. Murchison's illness. The enquiries of the Queen are no empty compliments, but reflect the general feeling of the public.

Dr. Jacoby, of New York, shows that the mortality in the Nursery and Child's Hospital in that city is enormous. In the former the rate has been forty deaths to sixty admissions.

Professor Erasmus Wilson, F.R.S., has published for the Royal College of Surgeons a catalogue of the Dermatological Museum, which he presented to that body when he endowed so munificently the chair of his favourite branch of medicine. The student in the Hunterian Museum, with this catalogue, cannot fail to learn much.

Dr. Argyll Robertson, in a paper read at the Medico-Chirurgical Society of Edinburgh, drew a distinction between Albuminuric Retinitis and Uræmic Retinitis. He dwelt on the importance of using the ophthalmoscope as an agent of diagnosis, as the eye-affection often gave the first indication of kidney diseases.

Dr. Turton, of Wolverhampton, recently mentioned the case of a girl, aged nineteen, who died from tympanitic distension of the abdomen in sixteen hours. On *post-mortem* examination, the stomach was found extending from the level of the nipples to midway between umbilicus and pubes. On allowing the gaseous contents of the organ to escape, it was found to contain a mass of black odourless, homogeneous matter, of about the consistence of putty, which was found on removal, to weigh seven and a half pounds. There was neither peritonitis nor obstruction.

Dr. Balthazar Foster recently showed at the Medical Association of Birmingham, on Nov. 10th, a heart in which both the right and left auricula-ventricular orifices were narrowed by endocardial inflammation. The patient had been admitted into hospital with well marked signs of mitral obstructive disease. The murmur at the apex was purely præsystolic. A few days before death, a murmur preceding the first sound was detected at the right edge of the sternum, and tricuspid obstruction was diagnosed. The *post-mortem* examination showed a funnel-shaped mitral valve, with an orifice only admitting a goose-quill. The tricuspid orifice only allowed the top of the little finger to pass; the segments of the valve were agglutinated, and the edges of the orifice studded with recent vegetations.

The argument that it is not indecent for female medical students to study anatomy and surgery side by side with males because female nurses discharge their duties under similar circumstances, seems to us a lame and impotent conclusion. Even indecency is relative, and that which would be a matter of course in one class would be highly objectionable in another.

As a matter of fact, female nurses do not voluntarily put themselves in the way of indelicate objects when male students are in the way.

In ward visiting nurses should, and usually do, stand aloof from the sight of indecent objects, which it would not be possible for them to avoid if they were surgeons instead of nurses.

But, we submit, that that duty which would not be so indecent as to forbid a nurse undertaking, might well be objectionable in a young lady, who hopes and expects to hold the position of a lady and to practice a learned profession. There are many things which a servant may do without disgracing herself, but which the mistress might not, and we, therefore, hold that there is no analogy between hospital nursing and lady doctoring.

The Journal of the Irish Medical Association called attention last week to a project for the appointment of an officer in whom the contract of the supply of medicines to all Irish Unions should be reposed, decided on by the Irish Poor-law Commisssioners, and to a sealed order, issued by them for the regulation of the system under which the functions of that officer shall be administered.

A "Poor-law Unions Apothecary," possessing the licence of the Hall, is to be appointed at a salary of £500 a year, with a residence, and whatever assistance may be neeessary.

He is to be appointed by the votes of a majority of the Boards of Guardians in Ireland, they being furnished by the Commissioners with a list of candidates and their testimonials, and it will be his business to "contract for, or purchase, the supplies estimated to be required, of the best quality and at the cheapest rate for which they can be obtained."

In the Circular which accompanies the order, the Commissioners explain the reasons which have led them to make this appointment—Firstly, on the ground of economy. They state that "great profits" are made by the contractors, and that inasmuch as the existing expenditure in drugs, in the Irish Poor-law, is £32,000 a-year, and the probable expense of the central depôt not more than £1,500, a considerable saving may result. Secondly: They desire to secure to medical officers the means of using medicines on which they can rely.

The *Journal of the Irish Medical Association* expresses its entire approval of the course the Commissioners have taken to remedy the most scandalous abuse which existed in the Medical Charities' system of Ireland. Every one will agree with acclamation, that it was a simple duty for the Commissioners to take the matter into their own hands, and that neither the contractors or the Boards of Guardians are worthy of the slightest consideration in the matter, and, if fault be found with the sealed order, it will much more probably be with its consideration to guardians than with its decisive and sweeping character.

In two respects, indeed, the order seems open to question. The function of the Poor-law Unions Apothecary introduces, it thinks, a new and commercially unfair principle into a branch of the public service He is to supersede all contractors, and to deal directly with the large wholesale houses.

It is a wrong principle for the public to save money by absorbing the legitimate profits of traders. It is enough for a Government department to make sure that those profits are reasonable, and that the article supplied is genuine, without constituting itself buyer and seller to those over whom it has control.

Moreover, the purchasing of drugs on so great a scale will afford a lasting temptation to those abuses which may be expected to creep into such a system. The distribution of much money and many favours will be in the hands of one man, and his responsibility not clearly defined, and a little laxity of supervision, may, at any time, produce as great evils as those for which we are seeking a remedy.

It would have been a safer and, apparently, more diplomatic course to confine the functions of the Poor-law Apothecary simply to determining the purity of the drugs, and the propriety of their prices, leaving the purchase and payment between individual contractors and Board of Guardians.

The other point which appears objectionable in the scheme is the placing of the appointment of Poor-law Apothecary in the hands of the Boards of Guardians. It is quite plain that the intellectual and social

material of which Boards of Guardians are made is quite unfit to pronounce judgment on any such point.

They will appoint a candidate because they have seen his name in the papers, no matter in what form; or because he pesters them with circulars and testimonials; or because he is of some favoured religion, or politics; or for any other reason which has nothing to say to his fitness; but they will *not* appoint him because he is learned, or industrious, or business-like, or experienced, or honest, or for the possession of any quality which might make him a good officer.

The election will be carried by the biggest bundle of testimonials, and the most persistent private ear-wigging, and the result will be a thoroughly stupid, inefficient officer, and "confusion worse confounded."

SCOTLAND.

EDINBURGH.—The Town Council by a large majority, have elected Lord Gifford one of the Senators of the College of Justice, and Mr. W. Chambers, late Lord Provost, curator of the University in room of Mr. Russell and the late Mr. Fyfe.

ROYAL MEDICAL SOCIETY.—Edwin Hinchcliff, M.D., Alexander Macdougall, M.B., I. Muir Howie, and William Livesay, have been elected presidents of this Society.

THE University authorities have give notice, that in future any offence committed by a student leading to conviction in a police court, will be treated as a university offence, and punished accordingly. This tardy exhibition of common sense on the part of the Senatus, will, we trust, prevent a repetition of the disgraceful "rows" the Edinburgh students were so fond of indulging in This session the number of students in the various faculties, is greater than in any year since 1832.

GLASGOW.—The increase of relapsing fever has necessitated a large increase in the accommodation for fever patients.

DR. ALEXANDER WOOD reports, "1. That the Heriot, the Talla, and St. Mary's Loch all afford water of a quality suitable for all the purposes for which it is required in a town. 2. That the Heriot is a better water for general domestic use than the Talla. 3. That the spring water of the Heriot and the Talla is superior to the lake water of St. Mary's. 4. That the construction of the necessary ponds for storing the produce of these springs would go far to deprive them of any superiority which they at present possess, and would certainly render the water supplied from such ponds inferior in some respects to that obtained from the natural lake. 5. That the analysis of the water of St. Mary's Loch shows it to contain a sufficient quantity of the salts of lime to remove all fear of the danger suggested in the letter of 'A Physician' especially when the copiousness of the supply of these salts from other sources is considered 6. That, under these circumstances, it appears to me that the water procurable from any one of the three sources of supply being suitable, the trustees should be guided in the selection by the questions of quantity, engineering difficulties, and comparative expense, and not by the opinion of any physician. 7. That the present supply of water in Edinburgh is manifestly insufficient, and that the poorer classes especially are not receiving enough to maintain them in a healthy state. 8. That should any epidemic disease appear among us, they will be less able on this account to resist contagion, or to bear up against disease if attacked."

DR. LITTLEJOHN, says, "The water of St. Mary's Loch is a very pure, and in my opinion, a wholesome water. It is remarkably free from organic contamination—the importance of which in the production of disease has only been satisfactorily established of late years; and while on a par in this respect with the Loch Katrine water, it possesses this advantage that its proportion of saline ingredients is larger, and therefore that it is still less likely to act injuriously on the leaden pipes used in its transmission, or on the cisterns in which it must be stored by the inhabitants. Its waters are not stagnant. They present a large surface to the pure air of a strictly pastoral region, and while several streamlets enter it, the Yarrow leaves it. As engineers and chemists have again and again pointed out, it possesses as a natural reservoir great advantages over all artificial collections of water secured by earthy embankments, such as are contemplated in all the other proposed schemes, and from the slight variations in the level of its surface in the driest seasons, it also contrasts favourably with natural reservoirs, such as those of our present water supply, which have been empty for months, and exposed to the disintegrating action of the air and sun."

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN NOVEMBER, 1870.

THE *following are the Returns of the Medical Officer of Health of the Association*:—

NAMES OF WATER COMPANIES.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia	before Boiling.	After Boiling.
	Grains.	Grains.	Grs.	Grs.	Degs.	Degs.
THAMES WATER COMPANIES.						
Grand Junction ..	19·23	0·050	0·091	0·005	14·9	3·4
West Middlesex ..	18·57	0·039	0·110	0·002	14·6	3·6
Southwark and Vauxhall ..	19·60	0·053	0·091	0·004	14·9	3·5
Chelsea	19·27	0·050	0·110	0·004	14·9	3·5
Lambeth	19·10	0·064	0.091	0·005	14·2	3·5
OTHER COMPANIES.						
Kent	26·60	0·004	0·175	0·000	20·0	5·6
New River	19·03	0·018	0·110	0·000	14·6	3·3
East London	18·23	0·014	0·110	0·004	14·8	3·4

NOTE.—The amount of oxygen required to oxydise the organic matter, nitrites, &c., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 104,073,197 gallons; and the number of houses supplied was 482,565. This is at the rate of 32·4 gallons per head of the population daily. The last official return from Paris stated that the average daily supply per head of the population was 29·3 gallons; but this includes the water used for the public fountains, and for the ornamental waters in the Bois de Vincennes and the Bois de Boulogne.

Correspondence.

LOCK HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask for a space in your paper to say a few words to the public on the important and, at the present moment, somewhat engrossing subject of Lock Hospitals? The impression on the minds of many, I believe, is, that they can only be looked upon as a means of aggravating the social evil already too glaringly and unblushingly paraded in most of our towns; whereas, properly managed, the very opposite result

may be and, I have every reason to believe, is attained. I took the matronship of the hospital from which I am now writing, about six weeks ago, with a view to help on reform. Though I was sanguine that *something* might be done, I am amazed to see what a field of rich and hopeful labour it presents to those who have the love of souls at heart. If a few of the many devoted ladies in our land would direct their attention to this neglected portion of God's vineyard, very much might be done, with His blessing, among these poor women, who, but for these institutions, would remain quite out of reach. Here, they are clean, in spite of themselves, and in clean clothing, shut in from the possibility of getting strong drink, and therefore more likely to listen to the advice given by the Chaplain, myself, or others; and this is not all—the very young, after a course of a few weeks or months of sin, being brought in here, may be reclaimed, their downward course stopped almost at the outset; some are restored to their parents; others sent to homes, as the case requires; some—many, indeed—will obstinately return to their sin, and we can only pray that God will have mercy on them at last. In this hospital an excellent system is adopted, of separating those willing to turn from their evil course from those hardened and determined to continue in it. The simple tale of one of these children (which many of them are) is briefly this—Being in a small place of service, having been placed there by her mother, she wished to get something better; fearing to tell her parents of her intention, she made up her mind to get a lodging, when she left that service, till she got what she wanted. The poor girl went, unwittingly, to a house of ill-fame—a month after she was brought in here, and will be placed, as soon as possible, in a Refuge, having been reconciled to her distressed parents.

This is only one case of many. This very day, a young girl has asked me to be sent back to her friends instead of going where she came from, desiring to renounce her evil course. I will not intrude further on your space, but will only add I am willing to give any further information to those *really interested*, if you will kindly allow letters to be forwarded to me from your office. I must ask that no letters will be written from idle curiosity, and that all shall be as concise as possible.

I am, Sir, your obedient servant,

MATRON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the review of my "Manual of Qualitative Analysis," which appeared in the PRESS of November 23rd, the Reviewer, after expressing his opinion that my work is better adapted for cramming students than that of Fresenius or the Giessen Outlines, adds "A student enters a government school with the intention of passing an excellent examination after devoting a few sessions to the study of a gigantic science, and he is generally successful in it if he has any amount of ability. But is this all? Do these young men represent those that in their day are to bear the heat and burden of their respective sciences? We opine not. As regards the workers in science, the crammed examination system has been an utter failure."

As the Reviewer evidently makes my book and its author responsible for the failure, as he thinks, of chemical education in a government school, I trust you will allow me to make a few remarks on his statement. Very few of the laboratory students of the College of Science, Dublin, undergo an examination, very few even ask for a certificate of attendance, the majority of the students are the owners of, or employées in, some kind of chemical establishment or manufactory, and they come to get a knowledge of practical chemistry in order that they may carry on their business operations more successfully. Many of them cannot even afford the time to attend one session, much less the two or three sessions the Reviewer talks about. Some of those living in Dublin or its neighbourhood can only afford a few hours in the day, or two or three days in the week. But, even with the short time that the majority of the students have been able to give, their labours, as regards the advancement of pure science, have not been altogether barren; they have contributed papers to the Royal Society of London, the Chemical Society of London, the British Association, the Institute of Civil Engineers, London (the Institute awarded the author of the paper the Telford Medal and the Telford Prize of Books for his contribution), the Royal Dublin Society, the *Chemical News*, the *Technologist*, the *Agricultural Review*, &c.; and if your Reviewer will take up such a work as the French one, by Pelouze and Fremy, he will find some of these students quoted as authorities on the subjects on which they have written; or, if he will look over the French "Chemical Dictionary," which he is at present reviewing, he will find in one article out of the few papers which the reader is referred to for further information, that two of these were the contribution of my students. I may add that five have been engaged by eminent chemists in London to perform analysis, and assist them in performing original researches; one has been appointed Professor of Chemistry in one of our most important colonies; one is the part editor of a London chemical journal; and two have started a chemical manufactory in the neighbourhood of London, which has been highly successful. This may not be very much; but a great part has been accomplished by evening students, and I shall be obliged if your Reviewer, or any other person, will point out evening students in any laboratory in England or elsewhere who have accomplished so much.

I remain, dear Sir, yours faithfully,

ROBERT GALLOWAY.

Royal College of Science, Dublin,
December 2nd, 1870.

CAUSE OF GONORRHŒA.

PROF. W. A. HAMMOND, of New York, in his "Lectures on Venereal Diseases," asserts his belief, which he supports by cases, that gonorrhœa may be introduced either by the virus of hard chancre, or by the virus of soft chancre, when the chancrous matter has been deposited for a certain length of time upon the mucous surface, without any abrasion being present, or without any chancre following. Vaginitis and urethritis may be induced by other causes, but true gonorrhœa owes its origin to the contagion of chancrous pus alone. He also believes that the gonorrhœa induced by the matter of a hard chancre will be followed by and may impart constitutional syphilis, just as if a chancre had been present. Dr. Hammond's opinions in this respect coincide with those of Hunter. The experiment of Ricord appeared to have finally decided the question that gonorrhœa was incapable of producing syphilis, and that they were totally different disorders. But the conclusions arrived at by Dr. Hammond are:

"1st. That the virus of an infecting chancre, when deposited on a secreting mucous surface upon which there is no solution of continuity, may give rise to gonorrhœa unattended by chancre, but which is syphilitic in its character, and capable of producing constitutional disease.

"2nd. The matter of such a gonorrhœa is capable of causing an infecting chancre, either by natural or artificial inoculation, which chancre is followed by constitutional syphilis."

Similar propositions are made about soft sores.

The observations and practical remarks of Mr. Morgan, of Dublin, which we lately published in this journal, confirm very much these observations. His experiments prove that the product of inoculation from a vaginal discharge in a constitutionally-infected woman is the characteristic pustule and non-infecting chancroid sore, which is capable of propagation in this form from one individual to another; indeed, it seems pretty certain that contact with a gonorrhœal or vaginal discharge in a case of constitutional infection may produce a gonorrhœa or a soft sore if there was any abrasion of surface. Thus, a soft sore is not very unusually associated with gonorrhœa derived from the one contact; but the conception of gonorrhœa and a hard sore is very rare indeed. The subject is daily becoming a more important one, and the observations of Mr. Morgan, in Dublin, confirming by direct experiment the remarks of Dr. Hammond, of New York, are entitled to careful consideration.

Charity Organization Society. — An influential meeting was held at the Vestry-hall, Piccadilly, on Wednesday last, when the following resolution was passed:—"That it is expedient to form in the Poor-law Union of St. James, Westminster, a committee for the purpose of organizing charitable relief and repressing mendicity.

Gleanings.

Adipose Deposits in the Omentum and Abdominal Walls of Woman as a Source of Error in Diagnosis.

Dr. Geo. Pepper read a paper on this subject before the Philadelphia Obstetrical Society and related three illustrative cases.

All three patients had experienced considerable anxiety at the occurrence, and in two instances they firmly believed themselves pregnant, so that one of them even had engaged her accoucheur. The third fancied herself the victim of ovarian disease, and was beginning to fail in health, owing to the ever-present dread this thought inspired. In the first case, the excessive deposition of fat took place at the termination of the menstrual life, and after an exhausting uterine hæmorrhage had been checked; in the second, after the cure of a profuse purulent uterine and vaginal discharge; whilst in the third, after a rather unusually abrupt cessation of the catamenia. In all, some accustomed discharge had ceased; and in all the deposition of fat took place principally in the abdominal walls, and probably in the omentum and various tissues of the abdomen and pelvis, without materially implicating other portions of the body. It appears improbable that, in any or each of these three cases, the enlargement of the abdomen could have been merely an accidental concomitant, for it so promptly followed the cessation of the habitual discharge, and continued to increase so regularly for a time, and yet came to a standstill, or diminished, without any material aid from treatment.

"The diagnosis of these conditions," Dr. P. remarks, "should be made only after a careful consideration of the history, and a thorough physical examination of the patient; for only by such a combination can an intelligent opinion be formed. The fact of a recent suppression of the menses, or of some other habitual discharge, and, coincidently with this, the abdominal enlargement, must strongly direct suspicion, especially if from her age, or other circumstances, it would appear improbable that the woman had conceived. As a rule, the more profuse the discharge has been, and the more sudden the cessation, other things being equal, the greater will be the deposit of adipose tissue, and the more profound the psychical impression on the patient."—*American Journ. Obstetrics.*

Ovarian Tumour; two Pregnancies during its Existence; Extirpation; Recovery, and third Pregnancy following.

Dr. A. B. Crosby records (*Michigan Univ. Med. Journ.*) an interesting case of this, the subject of which was twenty-eight years of age, commenced to menstruate at sixteen, and was married at twenty-five. Two months after marriage menstruation ceased.

Two months subsequently there was evident enlargement of the abdomen, which attracted little attention, because the patient was suffering from nausea. Six months after marriage there existed marked pain in the right iliac region. The abdomen was very prominent, and just below the umbilicus measured forty-two inches. The usual signs of pregnancy existed, and it was supposed to be complicated with ascites. At full term she was delivered of a healthy boy. After confinement the abdomen only slightly diminished in size. Six months after the birth of her child paracentesis abdominis was performed, and thirty-five pounds of a slightly amber-coloured fluid removed. A small, solid tumour, the size of a hen's egg, could now be detected. A month later Prof. D. Crosby saw the patient and diagnosticated ovarian dropsy. One month after this (June, 1863) the patient again became pregnant. In January, 1864, she was tapped, and in March was delivered of a healthy girl.

On the 15th of June following she was again tapped, after which, a tumour about the size of a pint bowl could be felt in the left iliac region.

During the latter part of the nine months after the last tapping the tumour increased rapidly in size, and the patient desired its removal; which operation was performed March 22nd, 1865. On September 1st, 1866, she was delivered of a living, healthy, male child, after a natural labour.

Quinine Manufacture.

The *Madras Quarterly Journal of Medical Science*, has published a number of official documents bearing upon the manufacture of quinine at the government plantations at Rungbee. The superintendent of the plantation gives the number of cinchona trees planted as 1,200,000. He proposes to extract from the bark of the prunings and trimming the alkaloid in its amorphous state, and to issue the same to the Inspector-general of Hospitals until such time as practice in the manufacture shall enable the separation and crystallization of quinine. Such great plantations, kept up at government expense, cannot fail in time not only to insure a sufficient supply of this essential drug, but also to materially reduce its price.

The Liver the Seat of Formation of Urea.

The latest researches upon the place of origin of urea, and especially the beautiful experiments of M. Gréhant, have demonstrated that the kidneys are by no means secretory, but purely excretory, organs for urea. Dr. Cyon, in the last number of the *Centralblätt*, publishes a few facts in the form of a provisional communication, to show that it is probably produced at the liver. The plan of experimentation adopted (in common with M. Istomin) was as follows: The whole of the blood was abstracted from the carotid of a dog, and a portion, after being defibrinated, was transmitted by means of mercurial pressure through the liver. Coincidently three canulæ were introduced—one into the inferior vena cava, the second into the hepatic artery, and the third into the vena porta. The results of careful analysis showed that the blood which had passed through the liver contained a much larger proportion of urea than ordinary arterial blood. In one experiment 100 c. c. of the arterial blood when defibrinated contained 0·03 grammes of urea; but, after having been passed four times through the liver, the same quantity contained 0·176 gramme.

On the Application of Carbolic Acid as a Local Anæsthetic in Surgical Operations. By J. H. Bill, M.D., Surgeon U. S. Army.

All who have handled this substance must have noticed the tingling sensation (not unlike that produced by aconite) in the finger tips and other parts touched by the acid, which presently passes into a greater or less anæsthesia. On trying to determine the amount of this anæsthesia with an ordinary æsthesiometer it was found not only impossible to distinguish two points, however widely separated, but even to recognize the presence of one.

The prick of the point was not felt at all as pain, nor was an incision productive of uneasiness. The experiment was, therefore, extended thus:—The radial side of the writer's left forearm was covered with a cloth soaked in a saturated solution for a half hour, then a streak was traced over the course of the radial artery with a camel's hair brush dipped in acid liquefied by one-twentieth bulk of water. This streak extended from the styloid process to near the elbow, and, after a few minutes, was rubbed off. An incision was then made with a common scalpel from a point about two inches above the styloid process towards the internal condyle for five inches, occupying as near as possible the middle of the streak made with the brush, and extending down to the fasciæ investing the flexor muscles (superficial) of the thumb and fingers, so that at its lower extremity the radial artery was exposed, and could have been ligated. This incision was unattended with pain, save where nerves distributed to, or passing over the muscular fasciæ were pricked or divided, and even in this case the pain was not at all unbearable. *The incision of the integument was painless*, and the writer would have been unconscious of the injury save from the sensation communicated to his hand holding the knife as it was drawn through the tissues. This observation or experiment was made nearly a year ago. It was applied practically at once to all minor cutting operations. The writer has not incised a felon or bubo since without successfully employing this method for preventing or greatly mitigating pain. Many cases could be given—one will suffice. David Harris, of Vancouver, applied with his second finger of the left hand highly inflamed from a felon, the parts much injured by burrowing of pus. A previous felon had been treated on another finger a few month before, and the requisite incision had given him exquisite pain; the patient, therefore, apprehended great suffering from any operation on the finger now diseased, and begged for chloroform. However, the finger was soaked for fifteen minutes in warm water containing three per cent. of carbolic acid, dried, and then a brush dipped in the concentrated acid drawn over the finger in the course of the intended incisions. These, two in number, were then made, using a thin edged scalpel by a slow sawing motion, allowing only the weight of the knife to make the

cut. The patient stated that he had suffered no pain, or not more than would have resulted from handling the parts. The parts healed at once. Sometimes it is necessary, after making an incision nearly through the integument, if sensibility becomes apparent, to brush out the wound made with some liquefied acid before extending the incision deeper. This was necessary in a palmar abscess treated by this method without pain. The writer has excised a small tumour partly by this plan. Buboes have been operated on painlessly, and in short, the writer can recommend the plan in any cutting operation where no dissection of the skin is involved, and where all the pain results from the cutting of the skin. It is hoped that it will be of special service to those who are compelled to operate without an assistant. The writer was thus compelled this summer to remove from his right hand, by an incision of over two inches in length, a large wooden splinter which had been thrust through the palmar fascia, and had lodged under the tendon of the lumbricalis of the index finger. It was done without pain, save where a nerve was divided. The incision healed without scar.

These facts, which the writer believes he is the first to point out, have theoretical relations of great interest which may be discussed in a future paper.—*American Journal of Medical Science.*

Tetanus.

The *New York Medical Journal* has collated a number of cases of tetanus, in which chloral was employed, both with and without benefit Heroic doses of opium have also proved successful in this disease. *L'Union Médicale* gives the experience of Dr. Chazarin, who practised for seven years in the French colony of Senegal. He mentions altogether twenty-eight cases, twenty of which, treated by various means, terminated in death. The eight others were snbmitted to the following treatment:—First day, 15 grains of gummy extract of opium in solution; second day, 22 grains; third day, 30 grains; fourth day, 37 grains; fifth day, 45 grains; and so on, increasing the dose each day seven grains if the symptoms did not improve. When 90 grains were reached, the doses were diminished in the same ratio from day to day. Of these eight patients one only died, and this in consequence of frictions of oil of turpentine imprudently undertaken on the advice of a neighbour. These cases deserve particular attention, though they are not very uncommon, as some analogous ones were published in *L'Imparziale*, of Florence, in the year 1868. Quinine was, however, in these latter instances added to the opium.

Extract of Belladonna in Cholera Morbus. By W. E. Whitehead, M.D., Assistant-Surgeon United States Army.

Having had occasion to treat several cases of severe attacks of cholera morbus this summer, and, after complete failure to effectually relieve the first patient, even after the use of free doses of opium for forty-eight or more hours, I determined to use the solid extract of belladonna; consequently, I ordered for the patient pills containing one-third to a grain of extract of belladonna; one pill to be taken every four hours. The first pill relieved the sense of constriction, or knotty pain in the region of the umbilicus, and after the third pill had been taken the bowels were freely moved, notwithstanding several purgative draughrs had been taken before I saw the patient, without effect.

This patient (female) took two grains of the extract altogether. Her recovery was rapid and perfect; no constipation, headache, or any unpleasant symptoms remained, as is very apt to be the case in the treatment of this disease with opium, or its alkaloids.

The result in each of the other three cases (males), treated from the first with the solid extract of belladonna, was the same as in the case above described, only that the recoveries were more rapid, no delay having been caused from the use of other remedies.

It has been, and is my habit, to order from the third to one-half of a grain of the solid extract of belladonna, made into as small a pill as possible—this sized pill to be taken every four hours; to be continued till the toxical effects of the medicine manifest themselves, or till relief comes, which latter is generally the case long before the former are manifested.—*Pacific Medical and Surgical Journal.*

Nature says it is stated that Prof. J. S. Smith, F.R.S., has been appointed to succeed the late Dr. W. A. Miller as a member of the Royal Commission on Scientific Instruction and the Advancement of Science.

Medical News.

University of London.—The following is a list of the candidates who have passed the recent second M.B. Examinations for honours:—

Medicine.—*First Class:* Curnow, John, (Scholarship and gold medal), King's College; * Irvine, James Pearson, B.A., B.Sc. (Gold Medal), and Roberts, Richard Lawson, University College.—*Second Class (equal):* Bruce, J. M., M.A., Aberdeen, University of Aberdeen; Burgess, W. F. Richardson, and De Liefde, John, Guy's Hospital; Pollard, Frederick, and Seaton, Edward Cox, St. Thomas's Hospital.—*Third Class (equal):* Carter, Charles Henry, B.A., and Smith, Richard Thomas, University College.

Obstetric Medicine.—*First Class:* Curnow, John (Scholarship and Gold Medal), King's College; * Burgess, Wm. Fred. Richardson (Gold Medal) Guy's Hospital; Pollard, Frederick, and Seaton, Edward Cox, St. Thomas's Hospital; Carter, Charles Henry, University College; De Liefde, John, Guy's Hospital.—*Second Class:* Irvine, James Pearson, University College; Barnes, Edgar George, St. George's Hospital,—*Third Class:* Smith, Arthur William, Guy's Hospital; Smith, Richard Thomas, University College.

Forensic Medicine.—*First Class:* Bruce, John Mitchell (Scholarship and Gold Medal), University of Aberdeen; Burgess, Wm. Fred. Richardson (Gold Medal), Guy's Hospital. *Second Class (equal):* Irvine, James Pearson, University College; Smith, Arthur William, Guy's Hospital.—*Third Class:*—Carter, Charles Henry, University College; Curnow, John, King's College; Seaton, Edward Cox, St. Thomas's Hospital.

At the remote city of Indianapolis an Academy of Sciences has just been formed under the presidency of Professor E. T. Cox. The exclusive object of the association is the cultivation and imparting of knowledge of the natural and physical sciences. Though the number of members at present does not appear to be large, it will, no doubt, like most other things in the Far West, increase rapidly. We (*Nature*) wish all success and a proper future to this the youngest society for the advancement of natural history.

The Census of 1871.—The Commissioners for the census of 1871 for Ireland are the same as in 1861, viz.: Mr. William Donelly, Registrar-General; Sir William Robert Wilde, M.D., and Mr. George W. Abraham, LL.D. The census in England will be taken by Major Graham, Registrar-General; Dr. Farr and Mr. James T. Hammick, assistants to Registrar-General; Mr. W. Clode acting as secretary. A staff of 100 clerks will be specially employed for digesting the returns; a work likely to occupy some three years.

Rag Pulp in Butter.—After melting a sample of butter purchased at Brixton, a large clot separated, and although the sample was left all night in a cool place, it did not again solidify. This led the *Food Journal* to an immediate microscopic examination, and proved beyond a doubt that rags in a state of pulp had been employed in large quantity. The rags themselves conjure up ideas sufficiently nauseous; but, in addition, *the dyes had not even been discharged*, as the filaments presented a great variety of magenta, blue, brown, and other colours.

A contemporary says that from an official report forwarded to it from Basle respecting the French prisoners, in the lazarettes in Germany, it appears that of these prisoners, who amount to above 150,000, many are ill, many suffer from wounds, and most of them are quite destitute. The almoner of the French prisoners in Ulm writes that in that place there are 1,000 sick and wounded, and that the means of aiding them are absolutely wanting. Typhus makes great devastation among these unhappy Frenchmen; the average number of deaths is ten daily. At Minden, there are 500 prisoners ill with dysentry, typhus, and small-pox; and the number is daily increasing. There is the greatest difficulty in relieving them, even in obtaining what is strictly necessary, for there is a want of everything, especially linen. Scarcely one of the fever-patients located in halls and barracks has a shirt to change, and many have no stockings. With the best will, it is impossible to do what is necessary, without clean linen, warm clothes, woollen jackets, stockings, drawers, &c., which are not to be had. The Basle charitable agency has received similar distressing reports from Marienberg, Coblentz, and other places, on the truly terrible destitution which prevails among the prisoners.

* Obtained the number of marks qualifying for the scholarship.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

Dr. Jacob, Maryboro.—Note and pamphlet received with thanks. Will be made use of next week.

Dr. Moore, Southgate.—Your letter is very acceptable and encouraging. We have entered your name on our subscription list, and thank you sincerely for your intention to influence others to support what you are pleased to term our "very practical journal."

Dr. West.—Thanks, but you did not give the address of your son in Calcutta to whom you wish the Journal regularly sent. We hope his estimate of the merits of the Medical Press will be as high as your own.

MISS GARRETT, M.D.

The women have won a decisive victory. They have carried Miss Garrett into the London School Board. Nay! more, they have placed her at the head of the poll. She distanced all competitors by 20,000 votes. No doubt, many men voted because there will be so many girl's schools under the Board, and a very good reason too, while we suspect all the women plumped for Miss Garrett. The etiquette in all new Boards is, that the member who has obtained the largest number of votes should take the chair at the first meeting. Hail then the chairwoman!

THE PHYSICIAN'S VISITING LIST.

The small pocket diary designed by Dr. Seymour Haden, and issued by Smith and Co., of Long Acre, has made its appearance in anticipation of the coming year.

We have not space to say what it contains, and we really have a difficulty in saying what, of desirable contents, it does *not* contain. It is neither meagre in necessary matter nor choked with information which would not be generally useful, and it is issued in a very convenient and at the same time, suitable shape.

MEETINGS OF THE LONDON SOCIETIES.

Monday, Dec. 12th.

Medical.—Mr. Teevan will introduce some "Practical Remarks on Stone with an Analysis of twenty-four Cases."

Thursday, the 15th.

Harveian.—Dr. Farlie Clark will read a paper "On Surgical Dressings."

VACANCIES.

Birmingham Children's Hospital.—Acting Physician. Election 27th inst.

Brixworth Union.—Medical Officer. Salary £78, with extra fees.

Stamford Infirmary.—House-Surgeon. Salary £100, with board and residence.

Metropolitan Free Hospital,—Honorary Surgeon.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Causes and Treatment of Lateral Curvature of the Spine. Second Edition. By Richard Barwell, F.R.C.S. London: Macmillan and Co.

Horses, their Rational Treatment, and the Causes of Premature Decay. By Amateur. London: Baillière, Tindall, and Cox.

The Pathology and Treatment of Venereal Diseases. By F. J. Bumstead, M.D. London: Trübner and Co.

Transactions of the Pathological Society of London. Vol. XXI.

Remarks on the Mode of Admission to our Medical Charities. By J. Thorburn, M.D.

The Chemist's and Druggist's Almanack and Diary for 1871.

British Journal of Dental Science; New York Gazette; Homœopathic Review; Food Journal; Science Gossip; The Shield, &c., &c.

APPOINTMENTS.

Adam, J., M.D., Medical Officer to the Asylum for Imbeciles, Caterham.

Blennerhassett, E., L.K.Q.C.P.I., M.R.C.S., Medical Officer for the Valencia Disensary District of the Caherciven Union, Co. Kerry.

Carter, W., M.B., Physician to the Liverpool Southern Hospital.

Caton, R., M.D., Lecturer on Comparative Anatomy and Zoology at the Liverpool Royal Infirmary School of Medicine.

Cayley, W., M.D., Assistant Physician to the Middlesex Hospital.

Chute, H. M., Assistant House-Surgeon to the Bristol Infirmary.

Dunkley, Mr. W., Assistant House-Surgeon to the Stockport Infirmary.

Harvey, H., L.R.C.S., House-Surgeon to the Hospital, Darlington.

M'Donnell, M. A., L.R.C.P.Ed., Medical Officer for the French park Dispensary District of the Castlerea Union, Co. Roscommon.

Topham, J., M.D., Honorary Physician to Torbay Infirmary, Torquay.

Townsend, Dr. Medical Officer for the Miltown-Malbay Dispensary District of the Ennistymon Union, Co. Clare.

Marriage.

Burke—O'Brien.—On the 21st ult., at the Catholic Church, Rathmines. Dublin, Joseph Burke, Esq., Deputy Inspector-General of Hospitals, to Susan Fraser, youngest daughter of the late Chas. R. Fraser Frizelle, Esq., of Stapolin, Co. Dublin, widow of the late Thomas O'Brien, M.D., Bengal Medical Service.

Deaths.

Adams.—On the 23rd ult., at Chatham, of apoplexy, Wm. P. Adams, one of the House-Surgeons of the Medway Union, aged 24.

Chambers.—On the 28th ult., F. Evans Chambers, M.R.C.S.E., of Upper Gloucester place, aged 36.

Colmer.—On the 27th ult., at Yeovil, Susan, the wife of P. S. H. Colmer, L.R.C.P.Ed., &c., aged 29.

Original Communications.

DR. CHARLES MAURIAC ON BLENNORRHAGIA IN WOMEN.

By Charles R. Drysdale, M.D., M.R.C.P.L., F.R.C.S.E.,

Physician to North London Hospital for Diseases of the Chest, Hampstead, &c.

I presume that many practitioners have found some difficulty in replying to the question put to us by some of our male patients suffering from urethral discharge—"Must this discharge have been caused by any virulent disease in the person who communicated it to me?" If this be the case, we shall, I think, be glad to hear what any person has to say on the subject, who, like Dr. Charles Mauriac, can lay claim to a wide clinical experience of virulent diseases in both sexes. That gentleman, in his translation of Dr. West's "Classical Lectures of Diseases of Women," has some really admirable remarks upon this thorny question, which I should like to introduce to the notice of English readers. The multiplicity of causes, says that gentleman, which may cause mucous or muco-purulent discharge of the internal or external mucous membranes of women, makes the question of blennorrhagia much more obscure in that sex than in men. We say that contagion constitutes the essential character of virulent vulvo and urethro-vaginal fluxes. No one denies it. It is clear that a catarrh, of which the secretion, placed in contact with the male urethra, provokes an affection of like nature, susceptible in its turn of transmission, is gifted with undeniably morbid specificity. But, if you ask whence arises this contagious catarrh, you will find insoluble difficulties arise. Can you affirm that the woman who communicates a blennorrhagia has received it herself by the method of contagion? Putting contagion aside, is it not possible that a utero-vaginal catarrh, arising under the influence of causes independent of all blennorrhagic contagion, should progress by the sole influence of ordinary morbid influences, to such a degree of virulence as to render it transmissible, and convert it into true blennorrhagia? In other words, is blennorrhagic catarrh always the result of contagion, or can it arise spontaneously?

In spite of all he has seen, Dr. Mauriac remains in doubt. Yet, he truly says, there are many doctors of great experience who affirm that any woman, whose genital secretions communicate blennorrhagia, is necessarily herself attacked by a blennorrhagia obtained from a virulent origin. They don't believe in the spontaneity of a specific catarrh. It may be admitted that this way of looking at the matter is true in the immense majority of cases. Yet, Mauriac is not so absolute as these gentlemen, and believes with others—and in particular with one of great authority in such matters, M. Ricord—that certain catarrhs of the genitals in women, whose source cannot be suspected, acquire of themselves the property of engendering that unexplained principle, that virus which makes the mucus and pus fit to cause in the male a legitimate blennorrhagia. When blennorrhagic inflammation has attacked the vulva, urethra, and vagina; when it is at its acme of acuteness, in all of its manifestations, and when the genitals are bathed with thick, greenish pus, acrid and irritating, the diagnosis presents no difficulty, especially if the antecedents bear no doubt as to the contagious origin of the disease. But, when the inflammation becomes slighter, and the secretion loses its purulence, no longer furnishing aught but a, more or less, abundant flow of mucus, whitish, and resembling the ordinary secretion in leucorrhœa, we are sometimes in doubt. In such cases, the persistence of urethritis is one of the best symptoms, one of those on which we can most surely rely when we affirm that a catarrh is blennorrhagic. When this symptom is absent (which takes place frequently enough), we have only as guides some corroborative circumstances, often of a doubtful character, especially if the woman has some interest in hiding or falsifying the truth. If the product of secretion were inoculable with the lancet, as the pus of soft chancre is, the question would be quickly solved. But this is not the case; and its application on a healthy mucous membrane, for example, on the mucous membrane

of the conjunctiva, would produce accidents too formidable for us to be authorized to seek a response in this mode of experimentation.

We all know how weak a point it is in the French system of incarceration of prostitutes with contagious diseases, that it is impossible to say when the time of contagion has gone by in many cases. Dr. Mauriac is well aware of this fact, and remarks that it would be very important, for practical purposes, to be able to fix, by means of characters worthy of confidence, the precise moment when a discharge, vulvo-urethral or utero-vaginal, which at first was virulent, had lost its specific qualities, and become incapable of reproducing a malady like that which has produced it. Unfortunately, there exists no positive sign. Doubtless, the contagious power of the secretion is generally in direct proportion to the proportion of pus it contains; and, so long as this secretion of the mucus of the genitals is greyish, or shaded yellow or green, we may be almost certain that the disease is communicable. But, when the blennorrhagic flux passes into the chronic stage, and, arrived at this phase of specific process, loses the character of clear pus to take on the aspect of leucorrhœa, it may remain contagious for a long period, or become so under the influence of great excitement, at the approach of menstruation, after excess in drinking of alcohol, or after unaccustomed stimulation of the generative organs. And, as to globules of pus, are these not met with in a multitude of discharges, of different sources, which are not at all contagious, and have never been so?

Thus, there is incertitude as to the question whether there can be, except in cases of contagion, a spontaneous generation of blennorrhagia; then uncertainty as to the characters which, with the exception of inoculation and of transmission, can permit us to affirm that a discharge is blennorrhagic; uncertainty as to the time when the alleged blennorrhagic discharge loses its virulence, and ceases to be transmissible; such is the *resumé* of what Dr. Mauriac has observed, when, leaving aside common and easy cases, he has attempted the delicate points of a problem, which has not yet been solved. In short, the partizans of absolute specificity have never demonstrated in a clear manner that it is impossible for a woman without blenorrhagia to communicate the disease. Some say, "every woman who gives a clap has received it before." This is true in 99 cases in 100. But are there not cases when the woman may create it entirely alone, and give it without having received it? So long as no one has demonstrated that the thing is impossible, Mauriac observes, he will be a specificist; but with some restrictions relating to the contagious catarrhs of women. Most will agree with this.

With regard to details, most modern authors have asserted that *virulent urethritis* is extremely rare in women. This view of the matter has been combated by A. Guerin in his work on the "Diseases of the External Genital Organs of Women." He declares that he has found urethritis in almost all women suffering from vaginal blennorrhagia. Whatever be its frequency, everyone agrees that the existence of urethritis is the most certain sign of the virulence of the disease. Simple, non-blennorrhagic, urethritis is extremely rare in women, even in little girls, when the vulva so often is inflamed, from teething, worms, or ill health, or want of cleanliness; but the functional effects which urethritis in women produces are far from being as marked as in men. Thus, it is often necessary to have recourse to a repeated exploration of the urethra to be sure that there issues, by pressure exercised from behind forwards, by means of the finger, a drop of pus. This exploration by the finger is indispensable when the inflammation, leaving the anterior portion of the canal, confines itself in the most hidden part, behind. There exists another variety of virulent urethritis, well described by Guerin as *external urethritis*. It is seated in two glands, which open close to, but external to, the meatus urinarius. It is not rare to see the inflammation of the vagina and vulva survive these. This discharge, however slight it may be, and although it may escape the researches of the doctor when the women wipe it away with a sponge or with their linen, gives the key to some mysterious contagions, whose origin we cannot trace, when a complete examination is not made.

The urethritis of women may be complicated by chancres, as is the case in men, or be symptomatic of such. For the most part, chancres of the meatus, or of the deeper parts of the canal, are infecting or syphilitic. They are not inoculable, and present an induration perceptible by the fore-finger introduced into the vagina. The hard, indolent, glandular swelling of the glands in the groin constitutes one of the most certain symptoms of urethral chancre, when it cannot be seen, or that its outer characters are equivocal.

Allied to the question of blennorrhagic urethritis, is the question of rheumatism of the same nature in women. Dr. A. Fournier, in a good memoir on this subject, relates how that, in a short time, he observed severe cases of blennorrhagic rheumatism in women as clear and as well marked as in men. All these women had urethritis. M. Fournier concludes from this, that blennorrhagic rheumatism is less rare in women than is commonly believed to be the case, and that it is connected with urethritis, and not with vulvitis or specific vaginitis. In the three facts he reports, the vagina was healthy; two of the women were pregnant.

In virulent or blennorrhagic urethritis in women, cubebs and copaiba are as useful as in the male, if administered at the epoch when the inflammatory symptoms are commencing to become less, either spontaneously, or after antiphlogistic treatment. But we may attempt in women a more energetic practice, *i.e.*, abortive cauterisation. For reasons easily divined, these are less dangerous than in males, and they almost always succeed in shortly arresting the specific inflammation, if we can touch the walls of the urethra in their whole extent. In order to allow cauterisation to touch the whole of the surface, we must press, with the finger introduced, out the vagina upon the whole length of the canal, from behind forwards. This being done, we introduce into the urethra a pencil of nitrate of silver, large enough to distend well the mucous membrane, and efface its natural folds, and this is slowly passed along the whole extent of the canal once or twice. This local treatment is without any danger, spite of its energy; it never causes retention of urine; the violent pains and slight bleeding produced diminish and stop pretty quickly. Sometimes, in a few days, it is necessary to recommence the operation, because the eschar falls, and the membrane again secretes pus. Copaiba or cubebs may be prescribed as adjuvants. If there co-exist with the urethral blennorrhagia, a vulvitis, or vaginitis of like nature, we must not count on a durable cure by this means, because the pus secreted on these two last surfaces must, sooner or later, come into contact with the meatus, and re-inoculate the urethra. To succeed in such like cases, we must treat at the same time the vulvitis and vaginitis. Urethral blennorrhagic injections, which are so useful in males, are of slight importance in women on account of the shortness of the canal.

As to *virulent vulvitis*, according to absolute specificists, it is always produced by a virus, and is the only kind transmissible by connexion. This inflammation may invade the whole vulva, or limit itself either to the clitoris, or to the internal surface of the labia majora or minora. It is superficial, deep, or follicular, &c. The liquid which bathes the diseased surfaces, at first serous, becomes rapidly sero-purulent, greenish-yellow, and sometimes bloody; it is gifted with such acridity that it determines redness or excoriations of the neighbouring parts. It exhales also, in dirty women, an insupportable odour. When blennorrhagic vulvitis is accompanied, as it is often, by a marked œdema, and when the surfaces of the mucous membranes are the seat of an irregular desquamation, and of bleeding and granular erosions, it is often very difficult to say if vulvitis is not the consequence of infecting chancrous erosions. In such cases, examination of the inguinal

glands is of great utility. If painful and swollen in non-infecting blennorrhagic vulvitis, in vulvitis with infecting chancres, they become very hard, voluminous, and generally remain indolent. When the follicles which open into the folds of the vulva ulcerate at their orifice, there result secreting surfaces, sharply cut, with greyish base, with swollen edges, and reddish border, which may be taken for soft chancres. Inoculation, in such cases, will remove doubts.

Among the complications of blennorrhagic vulvitis, we must point to the acute œdema of the labia minora, and the strangling of their base, an accident which presents an analogy with paraphymosis in males, and the inflammation and suppuration of the glands of Bartholine.

The treatment of virulent vulvitis varies according to the intensity and seat of the inflammation. When the process at once rises to a high pitch of acuteness and there is a tendency to propagation towards the deep parts, it is indispensable to have resource to an energetic antiphlogistic treatment. Local blood-letting, however, is rarely indicated; but prolonged baths, poultices, and soothing lotions are then of use. In cases, when the virulent catarrh of the vulva is accompanied by an acute œdema of the labia minora, it is good practice to make punctures on the surface with a needle or the point of a lancet. By thus giving issue to the serosity which infiltrates the interstices of the cellular tissue, we lessen, or make rapidly disappear, the phenomena of strangulation; but, before making this little operation, it is important to see that no chancrous ulceration exists.

In vulvitis of mean intensity, the above-mentioned treatment is applicable; but, perhaps, it is better to try abortive means—*i.e.*, to pass over the inflamed surfaces, after having first cleansed them, a hair pencil dipped in a solution of nitrate of silver. A solution of half a drachm to the ounce may be used, or less concentrated at first. This dressing should be used every four days, and it is useful to separate the diseased surfaces with dry lint, or lint dipped in styptic liquids, such as a solution of half an ounce of alum to the pint of water. General baths, sitz baths, frequent lotions with astringent lotions, such as a drachm of sulphate of zinc in a pint of water, with extreme cleanliness, repose and careful diet are the adjuvant means which must never be neglected. When the inflammation of the vulvar follicles has ulcerated their surfaces, it is sometimes necessary to touch the ulcerated points with a pencil of nitrate of silver, and not to allow the pus to remain on them. Abscesses in Bartholine's glands, or in the cellular tissue of the labia, ought to be opened early on the side of the mucous membranes, and by a pretty free incision to allow the pus to flow more easily.

(To be continued.)

CLINICAL MEMORANDA.

SUBCUTANEOUS INJECTION OF MORPHIA WITH CASES.

Reported by JOHN W. MARTIN, M.D., Assistant-Surgeon to Mayfield Factory Dispensary.

(*Continued from page* 391.)

CASE 6.—Mahony, æt. eighty, a farmer, suffering from *strangulated right inguinal hernia.* Notes taken Sept. 15th, 1870.

About half-past twelve o'clock, midnight, my father was called to see this patient, who resided some four miles from our residence, I accompanied him. The account given by the messenger, at once directed our suspicions to the occurrence of strangulated hernia, the accident having taken place at seven o'clock in the evening, so we went fully prepared for all hazards. About half-past one we reached the patient's house. On examining, we found a very large, tense, tumour, in the right side of the scrotum, from the neck of which, extending through "the ring," to the loins and back, severe pain was felt by the patient. There was some tenderness on making pressure.

The patient had, for a long time, been the subject of double inguinal hernia, for which he neglected to wear a proper truss. He was suffering severely from the pain already mentioned; the bowels had been slightly moved the preceding day; the abdomen was very tense and tympanitic. There was no vomiting; tongue clean and well protruded; pulse firm and regular, not much accelerated. A slight attempt to return the gut by taxis, making no impression on the extruded mass, at the suggestion of my father, I injected subcutaneously into the right groin one-third of a grain of morphia. For three-quarters of an hour, a firm and continuous pressure was kept up on the tumour, during which time the ether spray was kept constantly playing upon its surface, to promote contractions of the muscular fibres of the dartos. The full effects of the morphia not becoming apparent, another one-third of a grain was injected into the left arm, at the insertion of the deltoid muscle. About half-an-hour subsequent to the injections, the patient was fully morphianized: in the meantime the ether spray was kept continuously playing upon the tumour, which gradually contracted, and got very cold. At three o'clock, a warm water, sugar, and salt injection, was administered per rectum, part of it only returning through the tube with a little flatus. At half-past three, on my father desisting from the use of the ether spray, he again tried gentle taxis and, to our great gratification, the whole mass glided up into the abdomen.

Were it not for the *full* effect of morphine being so quickly obtained (one-and-a-quarter hours) by the hypodermic method of administration and the action of the ether spray, both my father and myself are confident that our attendance upon the case would have been greatly prolonged, and in all probability, operative measures would have been necessary for the reduction of the hernia.

CASE 7.—Patt Power, æt. sixty, labourer, *pain in the right lumbo-iliac region*, probably due to the passage of a calculus along the ureters. Notes taken Aug. 27th, 1870.

The pain was shifting in character.

1st. Felt severely over the ilio-cæcal valve.

2nd. Followed the distribution of the branches of the lumbo-sacral plexus, especially along the sciatic nerve.

3rd. In the lumbar region of the affected side, along the crest of the iliac bone, and down the course of the right spermatic cord to the scrotum, the pain was very violent, and the constitutional disturbance severe.

When first called to see him, he was almost howling with pain. The following symptoms pre-sented themselves to my notice:—

Abdominal muscles thrown into violent contraction; venous circulation engorged; marked tenderness to pressure in the region of the right kidney. Obstinate constipation; tongue furred and indented; pulse 112, weak, and general feverishness.

Treatment.—Bowels acted upon by aperients, and strong anodynes with hot stupes and turpentine applications failed to give the slightest relief. I then injected one-third of a grain of morphia, and with the immediate result of ease to the pain; the good effects were apparent in less than two minutes. This was about four o'clock in the evening; passed a good night, and next morning the bowels, which had not responded well to the aperient medicine given the previous day, were well and naturally opened; had a good day until four o'clock, when he was again attacked with pain, rendering a repetition of the injection necessary with a similar result to that previously obtained. Placed him on R Liquor potassæ, ℥j.; tr. hyoscyam., ℥ij.; doses ter die. Linseed-meal poultices over the seat of pain.

Gradually improved, but, for some time, whenever he went to pass water, he felt a pain shooting along the course of the ureter to the bladder on the affected side. Urine on examination was clear, acid and albuminous on boiling.

In this case the good effects of the hypodermic method of administering morphia were most marked.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XVI.

PRECIPITATION OF SEWAGE WITH THE SALTS OF ALUMINA AND IRON.

THE *salts of iron* have been used for more than a hundred years as disinfectants of night soil and foul water, and they have, as already stated, been the subjects of numerous patents. The most important of these were the patents of E. Brown and C. F. Ellerman, both of which were granted in the year 1847. Brown's invention dates from the month of February of that year, and it professes to be a means of "neutralising the odious and noxious gases emanating from fecal substances, or as it is sometimes termed, the 'disinfecting' of such substances, whereby they may be preserved, in order to their being manufactured into carbonic compounds applicable as manures, without injury to the public health, or to individuals engaged in such collection and manufacture;" and among the substances employed for this purpose were the sulphates and chlorides of iron. In the month of October of the same year Mr. Ellerman obtained a patent for "certain processes or methods of rendering feculent, excremental, and other matters inodorous, and of disinfecting, and also of retarding, the putrefaction of animal and vegetable substances." The chemical preparations which he used were the crude chlorides, and pyrolignates or acetates of iron. Mr. Edward Brown's invention does not appear to have commanded much attention, but Mr. Ellerman's was brought prominently into notice, and was frequently made the subject of public inquiry. We examined his liquid shortly after the date of the patent, and found that it was a strong solution of perchloride and pyrolignate of iron, having a specific gravity from 1336 to 1443, and containing from 24 to 43 per cent. of these ferruginous salts. The retail price of the preparation was eighteenpence a quart, but Mr. Ellerman offered to sell it wholesale for ninepence a gallon. Directly after the patent was obtained, the deodorising effects of the liquid were tried by Dr. Sutherland and the late Dr. Duncan, of Liverpool, and in the following year (1848) its action was still further investigated by the late Dr. Ure and Mr. Scanlan, all of whom reported most favourably of its disinfecting power, when compared with the well-known deodorising solutions of Sir William Burnett, Labarraque, and Ledoyen. Our own experiments, however, at that time did not furnish equally satisfactory results; for we found that 100 grains of Sir Wm. Burnett's solution of chloride of zinc, of specific gravity 1594, were quite as effective in deodorising sewage as 470 grains of Ellerman's solution, of a gravity of 1443. Mr. Haywood, also, the engineer of the City Commissioners of Sewers, inquired into the subject, and reported that when Ellerman's solution was used in the proportion of three gallons to a cubic yard of night-soil, it was not so perfect in its deodorising power as five pints of a solution of chloride of zinc. In the same year (1848) Mr. Hodgson reported to the Metropolitan Sewers Commission, that when the solutions were used in sufficient quantity to remove the sulphuretted hydrogen and ammonia from a cubic yard of night-soil, it required eleven and a-half quarts of Ellerman's liquid to do the work of one quart of Sir Wm. Burnett's. More recently, however, in 1859, the deodorising power of a strong solution of perchloride of iron, called Dale's liquid, was thoroughly investigated by Drs. Hofmann and Frankland, and subsequently by the late Dr. Miller, for the Metropolitan Board of Works, who were anxious to prevent as far as possible the putrefactive decomposition of the sewage in the River Thames during the hot summers of 1857 and 1860. The solution which they employed had a specific gravity of 1450, and its price was sixpence per gallon. This was compared with the effects of chloride of lime, costing £12 a ton, and ordinary caustic lime, at sixpence a bushel. When used in quantities of equal value they found that the perchloride of iron had a marked superiority over the two other disinfectants, and that chloride of lime was more powerful than quicklime; in fact, they ascertained that an immediate deodorisation of 7,500 gallons of sewage was effected by each of the three agents when used in the proportions of half a gallon of perchloride of iron, three pounds of chloride of lime, and one bushel of lime. The quantity, therefore, required to deodorise a million gallons of sewage, and the cost thereof, in each case, were as follows:—

	£	s.	d.
86 gallons of perchloride of iron .	1	13	3
400 lbs. of chloride of lime . .	2	2	10½
132½ bushels of lime	3	6	6

But the permanency of the deodorising effect of the several substances was very different in the three cases; for, they say, that after two days the sewage disinfected by lime became slightly tainted, whilst that deodorised by chloride of lime and perchloride of iron remained perfectly odourless. At the end of three days the limed sewage had become decidedly offensive, whilst the other two specimens still remained free from smell. After four days the odour of the limed sewage had become worse, but that treated with chloride of lime likewise began to exhibit an offensive character, whilst the sewage to which perchloride of iron had been added remained perfectly inodorous. Even after the lapse of nine days the condition of the latter had not changed. The chief cause of the decomposition of the deodorised sewage was no doubt the organic matter contained in the precipitate, and therefore they recommended that the suspended matters should be removed from the defæcated sewage as soon as possible. But as this was not practicable in the case of the London sewage, the proposition of Dr. Hofmann and Dr. Frankland to add perchloride of iron to it without separating the suspended matters, was objected to by Dr. Letheby and Dr. Odling in their reports to their respective local sanitary boards. Dr. Odling, indeed, was of opinion that the action of the perchloride under these circumstances would be much the same as that of lime, though perhaps a little more permanent, for it would produce a black sludge of precipitated mud which would be scarcely less liable to putrefactive decomposition, and would be more objectionable to the eye, than the undefæcated sewage; whereas the clarified sewage, deprived of this mud, might be safely discharged into the river. Dr. Letheby, in his report to the Commissioners of Sewers for the City, expressed himself to nearly the same effect, saying that the mere addition of a precipitant, without the separation of the feculent matters so precipitated, would be worse than useless. He also attached importance to

the presence of a large quantity of arsenic in Dale's solution, which, by combining with the iron, would be found in the precipitate. According to his analysis of a sample of the perchloride furnished to him by Mr. Dale, as that proposed to be used by the Metropolitan Board, there was enough arsenic in it to yield as much as a hundredweight and a-half of this poison to the Thames daily, if used in the quantity proposed by the chemical referees; and all this would be retained by the precipitated mud, giving a proportion of one part of arsenic to three thousand parts of the precipitate. This, however, was thought lightly of by the referees, who said, in their reply to his report, that it was their "deliberate opinion that even were the perchloride of iron to contain ten times the maximum quantity of arsenic observed by Dr. Letheby, its application for the purposes contemplated in our report could not afford grounds for the slightest apprehension of danger;" but in answer to this it was very properly asked,—What would have been the conclusions of these gentlemen if in their professional capacity as witnesses for a prosecution, they had ascertained that a manufacturer on the banks of the Thames was daily discharging into the river a quantity of refuse containing as much as a hundredweight and a-half of arsenic? and what also would have been the undoubted result of a legal prosecution, if the Conservators of the river had, in the exercise of their duty, applied for an injunction to prohibit such a practice? It is fortunate for the public that the question has been re-examined by Dr. Frankland, in his capacity as one of the Royal Commissioners appointed to inquire into the pollution of rivers; for he now suggests that, "any liquid which, in 100,000 parts by weight, contains, *whether in solution or suspension*, in chemical combination or otherwise, more than 0·05 part by weight of metallic arsenic, shall be deemed polluting, and shall not be admissible into any stream." In point of fact, it is manifestly of the greatest importance that the precipitate produced by the chemical action of perchloride of iron in sewage, should be carefully removed from the defæcated water, and not allowed to pass into the stream.

In the years 1859 and 1860, attempts were made to deodorise the sewage of Croydon by means of perchloride of iron. It was used in the proportion of from 120 to 140 gallons of Dale's liquid, to from 800,000 to 1,400,000 gallons of sewage; that is in rather more than double the quantity recommended for the Metropolitan sewage; but as the separation of the suspended matter was not properly effected, the results, as might have been expected, were not satisfactory; for the black precipitate of sulphide of iron contained in the effluent water, gave it a disgusting appearance, and marked in a very objectionable manner the exact course of the undefæcated sewage discharged into the river; besides which the precipitate adhered to the herbage upon the banks of the stream, and formed an offensive slimy deposit. As in the case of lime, and every other precipitating agent, it is evidently essential to the success of the process that all suspended matters should be carefully removed from the effluent water before it is discharged into a running stream; and this appears to be effectually accomplished by means of subsidence and filtration at Ealing, where the sewage is treated with lime and a cheap salt of iron made on the premises by a process recommended by Professor Way. The lime, in a slaked condition, is added to the sewage as it enters the works and is passing onwards to the subsiding tanks—where the precipitate produced by the lime and the other suspended matters of the sewage subside; and at the last subdivision of the tanks, a solution of iron salt is allowed to run into the defæcated sewage water in a graduated manner—advantage being taken of a slight fall to move a little water wheel, which assists in effecting the mixture of the iron salt with the sewage water. It then flows upwards through two filter beds, and is discharged from the works in a nearly bright and inoffensive condition. Professor Way has reported on the process, after having made more than thirty visits to the works since the month of July, 1869—two-thirds of which were during the hot and dry months of last summer; and although the state of the weather necessarily affected the process, yet he says:—"Since the system has been in good working order, I have considered the result to be very satisfactory. The effluent water, though not absolutely bright, has only a faint milkiness, which a more liberal use of chemicals would entirely remove. It is free from smell, and samples that have been kept for weeks have only in rare instances become offensive." On a former occasion, in 1868, when merely subsidence and filtration were practised at the works, the defæcation of the sewage appears to have been very effective; for a sample of the effluent water, analysed by Dr. Letheby, for the Conservators of the river Thames, was found to be perfectly transparent, and free from offensive odour. It contained only fifty-six grains of solid matter per imperial gallon, all of which was in solution, and it consisted of calcareous salts, chloride of sodium, and alkaline nitrates, with a very little organic matter and ammonia. The liquid, in fact, was so absolutely inoffensive, that, on the certificate of Dr. Letheby, the Board of Conservators permitted it to flow into the Thames; and we are not aware that any offence has been created thereby. Professor Way, in speaking of these filters, says in his recent report—"They are, in my opinion, of very great importance in carrying out any process of purification of the sewage before it is discharged into the Thames. Without them it would be impossible, by the best precipitants known, to clarify the sewage in the tank; for no matter how perfect the system of precipitation may be, there is always some portion of flocculent matter which will not settle, and which can only be removed by filtration. These filter beds are an excellent feature of the Ealing Sewage Works;" and now that the process of precipitation is superadded to that of filtration, he considers the works to be among the most perfect, if not the most perfect, of their kind in the country. The two depositing tanks, which, like the filters, are in duplicate, are each sixty-four feet long, ten feet wide, and ten feet deep. They are divided into five compartments by cross planks, having small openings at the top for the passage of the sewage, and their total capacity is about 12,000 cubic feet. The first filter is composed of gravel, thirty feet long, ten feet wide, and two feet thick, and the second filter is of fine sand, sixty feet long, ten feet wide, and two feet thick. The population of Ealing is about 8,500; and the quantity of sewage received at the works amounts to about 400,000 gallons a day, or nearly 2,000,000 gallons a week. In summer time, when the chemicals are most freely used, the weekly proportion of lime is one and a-half square yards, or about 20 cwt. (costing 20s.), and the amount of the iron preparation is 15 cwt. (costing 6l.); but in winter time less would be used. In fact, according to the estimate of the borough surveyor, Mr. Charles Jones, the average annual cost of the works

for chemicals, labour, &c., would be about £325, from which there is to be deducted the sum paid by farmers for the manure. This, at present, is about £60 a-year; but if the precipitate were mixed with town refuse, as at Northampton, it would realise much more.

Sulphate of iron, in the form of weathered shales or lignites, and copperas has also been used, either alone or in conjunction with other things, for the deodorization of sewage and nightsoil. The patent of Mr. Richard Dover, for example (1851), claims the use of acids with iron filings or oxide of iron and protosulphate of iron—the defæcated sewage being filtered through charcoal, peat, &c. Later still, in 1853, Mr. Herapath's process was a combination of one part of sulphate of iron and four parts of burnt magnesian limestone—the mixture being intended to precipitate the phosphoric acid of the sewage in combination with the magnesia, as well as the sedimentary matters. The process was tried for some time at the sewage works of St. Thomas, near Exeter, when it was found that a ton of the materials produced two tons of dry manure, at a cost of 17s. a ton; but the process was not remunerative, and was therefore abandoned. More recently, a preparation of dry copperas, called Mudie's disinfectant, has been used for the deodorization of drains, stable manure, and nightsoil. It freely absorbs the ammonia and sulphuretted hydrogen of such matters, and renders them inoffensive. It has, therefore, been extensively employed in France, for the purification of slaughter houses, ditches, drains, &c. Very recently, it has been examined by Dr. Letheby and by Mr. Crookes, who say that it is well fitted for this purpose, although it is hardly suited for the defæcation of sewage. Lastly—the process of MM. Jules Houzeau and Eugène Devedeix, of Paris, which was patented in 1866, consists in the use of lignites, containing sulphate of iron, or of sulphate of iron itself with lime and coal dust. This process has been extensively tried at Bradford by Mr. Holden, and hence it is generally called Holden's process. About 130,000 gallons of Bradford sewage are daily treated with the proper proportion of sulphate of iron, and then with caustic lime, previously slaked, and coal dust. The mixture passes into a series of subsiding tanks, where the time of flow is about twenty minutes; and thus the precipitate falls and leaves a clear, supernatant liquid, which is quite inodorous. All the sedimentary matter of the sewage is thus got rid of, as well as about half of the dissolved organic matter. The precipitate when dried in the air contains about forty-three per cent. of organic matter, and rather less than one per cent. of phosphate of lime. The organic matter is not very rich in nitrogen, and, therefore, the manure is not of much value.

Hospital Reports.

LONDON HOSPITAL.

Very considerable improvements have been lately thoroughly carried out at the London Hospital, and especially with reference to clinical instruction, which has been organised on a complete basis, and will not fail to have an influence even on so old and renowned a school of medicine as that at the east of the metropolis. Before examining fully the method of instruction, we propose to give a summary of the history of the London Hospital and its Medical College.

The establishment of the London Hospital dates from the year 1740, when a few benevolent persons (the foremost of whom was Mr. John Harrison, the first Surgeon to the Charity) opened a small Infirmary in Featherstone street. This locality was speedily changed for Prescot street, Goodman's Fields, and the need for additional accommodation soon becoming apparent, a portion of the present building was opened in 1757. Not long afterwards the Governors were incorporated by Royal Charter. The West Wing was opened in 1831; the East Wing in 1842; and the Alexandra Wing in 1866.

The progress of the Hospital as a House of Refuge for the Sick Poor may be gathered from the fact, that while in the first eighteen months of its existence it received only 227 In-patients and 2,188 Out-patients, the Registers of the twelve months ended 31st Dec. 1869 embrace a total of 4,398 In-patients (exclusive of 460 remaining under treatment at the beginning of the year) and a total of 49,976 Out-patients.

The position of the London Hospital in the neighbourhood of Docks, Factories, and Workshops, renders it, probably, one of the largest Accident Hospitals in the world.

The London Hospital contains about 570 beds, varying in appropriation according to circumstances, but at present thus allotted, namely:—

For Accidents and Surgical Cases	320
For Medical Cases	155
For Diseases of Women	12
For Children under Seven Years of Age	40
For Female Syphilitic Cases	15
For Ophthalmic Cases	11
Extra Beds in various Department as required	17
Total	570

Maternity cases are attended at their own homes in numbers proportionate to the available staff of students. 677 cases were thus attended in 1869.

The large Out-patient Departments not only embrace general, medical, and surgical practice, but have the advantage of special arrangements for the treatment of patients with diseases of the eye, ear, skin, and throat, as well as dental and obstetric cases.

The London Hospital stands out prominently as one of the most active Hospitals in the capital in the onward movement of medical education.

Mr. W. Spencer Watson read an

ABSTRACT OF A PAPER ON SQUINT, AND CASES OF FAILURE OF THE OPERATION OF STRABOTOMY.

The causes of failure were enumerated under the following heads:—

An Analysis of 103 *Cases of Convergent Strabismus.*

Age under thirty years, in		100
,, over ,, and under thirty-six years, in		3
Total		103
Family tendency traced in about ten cases.		
Hypermetropia in one or both eyes		69
Myopia in one eye associated with Hypermetropia in its fellow	2	5
Myopia in both eyes	3	
Amblyopia due to Intro-ocular causes as ascertained by the ophthalmoscope, or inferred from symptoms, such as Nystagmus, in	20	46
Amblyopia due to nebulæ of the cornea or leucomata	7	
Amblyopia due to unascertained causes, some probably from Astigmatism, and others from disuse of the squinting eye	19	

Analysis of Cases operated on for Convergent Strabismus.

Result of operations in 99 out of the 103 cases. The operation being deferred or declined in 4 cases.

One eye operated on in	38 cases,—Good results ..	36
Both eyes ,, at one sitting in ...	44 ,,	
Both eyes operated on, with an interval between the 1st & 2nd operations in	13 ,,	
	95	
Notes deficient as to whether one or both recti were divided in ...	4 ,,	
Total ...	99 cases.	

Successful result in	73
Partially successful result in	12
Slight improvement in	4
Divergent Squint (subsequently corrected) in ...	3
Results not known in	7

Operation by restoring the position of the Internal Rectus, successful in	1
Total ...	25

1. The pathological conditions were in some cases misapprehended. It had been supposed to depend, in ordinary cases, upon mechanical obstructions to the movement of the muscles or to bands of fascia. But from the free mobility of the squinting eye when the other eye is closed, this was clearly an error. From an analysis of 103 cases of convergent squint, it was shown that in at least two-thirds, hypermetropia was one of the conditions present in squint. At the same time retinal changes (in some cases due to pressure of the optic nerve against the side of the eyeball), nebulæ of the cornea, opacities vitreous, and other causes of impairment of sight in one or both eyes had a material influence in determining the permanent character of a strabismus, which would otherwise have been only intermittent, or would have been overcome by increased exertion by the accommodative apparatus, without convergence of the axes of the eyes.

2. The operation may fail from its employment in improper cases. For instance, where there is eccentric fixation from any cause, an apparent strabismus is seen, and in such a case an operation would give rise to dyspepsia, and would not probably be any improvement in the patient's condition, unless the second eye was very much impaired in its visual power. Or, again, strabismus may be apparent in cases in which one eye is very much larger than the other, from the presence of progressive myopia in one, and a normal condition in the other. In consequence of this want of symmetry, the cornea of the smaller eye appears to be much nearer the inner canthus than that of the larger, and this appearance might mislead the surgeon in a hurried view of the case.

3. The operation may be improperly performed, either by missing the bend when passing the blunt hook, or by dividing the tendon too far away from its sclerotic insertion. Cases of various kinds of failure from improperly performed operations were adduced, and some hints given as to how such accidents might be avoided.

4. The after treatment may be improper, and so cause failure. The patient may object to a second operation when the first has been insufficient; or he may object to the use of spectacles; or the reflection not having been ascertained, the surgeon may neglect to prescribe the necessary glasses; or the eye operated on may be kept covered up too long after the operation; or sutures may be omitted when required; or proper exercise of the eye after operation may be neglected; and in all these cases imperfections or complete failure may result.

Mr. Watson then stated in what cases an operation for squint should be avoided, or deferred. In particular cases of periodic squint, cases of apparent squint, squints in very young children in whom the after-treatment by glasses cannot be effectually carried out, cases of intra-ocular tumours, cases of brain disease, and cases of paralytic squint in the early stages. He then made a few observations as to the importance of adapting the kind of operation to the size of the squint, and the advantage of using the strabismometer before operating in all cases. The strabismometer of the late Mr. Zachariah Laurence being the most convenient and effectual.

* Probably the result of progressive posterior staphyloma.

ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.

The Annual Session was held on the 2nd and 3rd as usual, when much business was transacted, and some very interesting papers were read.

Dr. Richardson, who retires from the Presidency this year, and has been appointed President of the Council, delivered the address on

"THE FUTURE OF PHYSIC,"

of which we give an abstract:—

"Indulging one day in a luxurious day-dream by the seaside, it came to me that it would be a pleasing and useful task to devote occasional hours to the construction of a history of the science of medicine of the Victorian era . . . to write of the men who, moving actively amongst us at home and abroad, were worthy the pen of the honest historian . . . to narrate the natural history of diseases we see now around us in our daily tasks, that they who come after us may know with what we had to contend, and may compare our present practice with their own . . . that they may measure faithfully the course and progress of curative art, from this epoch to theirs. So vividly did the scope and character of the work appear before me that, even to minuteness of its detail, the plan was fixed in my mind; and since then I have found the labour of carrying it out a natural and agreeable pursuit, the which if I like to accomplish it, will perchance yield a work likely to live long when I am dead. As I have been writing on the past and present, a vista has often opened of the future of medicine, of the courses which medical science will take under the influences of changes of thought respecting the physical forces of the universe; of the new bases of the science, and of the perfections that will spring from them; of the greater knowledge of life and functions of life; and of the more certain modes of preventing and curing disease. Therefore I have been led to ask, what can we, who now exist, do for the future? What are we doing for it? Are we doing the best we can for it, or can we amend? In these contemplations I have founded the subject of the present discourse. At first sight the position of the present, from which we start, is neither assuring nor promising. A severe critic, with no intention of untruth, might say of us that we live and breathe in uncertainty; that, socially, we appear to dabble with questions of legislation without either teaching or influencing the legislator; that we appear to trust to Government protection for the right to apply our skill, and, instead of aiming to cast away the oppressive shield it loans to us at bitter interest, are ever wailing for the shield to be made stronger and heavier; that we appear to rise to prac-

tice on the paper wings of advertised emptiness, filling the sheet, not with painful touch of scientific industry and unsparing fact, but with the egotism of belief that each of us has done what others have not done and cannot do, though they religiously strive to follow our lead; that scientifically, we are incoherent and chaotic, and, like all chaoses, jarring, without reason; over proud of what we really do, and deaf to the demand that we must do more or be trusted less. . . . Be it my duty to indicate a leaf or two of the day-book of our life that may be revised wisely, a leaf or two that may be torn out wisely, or elaborated before that book passes into that unknown where it is ours no longer, either to cast, tear up, revise, or preserve. If we begin with what may be torn up, we come to a heap of mouldy leaves, supposed to contain some hidden virtue for making us powerful and respectable, but chiefly powerful, in the world. They are docketed as papers between the Profession and the State . . . papers that have cost us more trouble and more money during the present century than all our scientific and practical works since we became a profession. For the purpose of cultivating these leaves, or preparing soil for them, great voluntary organisations have been instituted during the era, which bodies, in one way or another—in eating, drinking, travelling, speaking, organising, disorganising, quarrelling, fraternising, writing, advertising, and printing—have, within Her Majesty's reign, disgorged themselves of not less than one quarter of a million of Her Majesty's portraits in sovereign gold. While another legal organisation, more compact, much more practical for itself, and much more determinate, has skilfully extracted by and for these same leaves some tens of thousands more. The leaves themselves have simply taken from us that patience of steady endeavour which trusts for the development of the most natural of sciences on the pure development of natural knowledge, and have produced amongst us separation of interests and galling unbrotherly bonds; they have drawn our men of genius for natural research from the noblest to the commonest work. . . . In suggesting the entire isolation of medicine from the trammels of bad legislation, I refer to the separation of science only. Present legislation leads to the existence and sustenance of rival boards, having rival powers and privileges, that induces us to make endless, wearing, and useless efforts to put down quacks by the power of law as against that of knowledge, and that fosters a stubborn belief in our security as a class, which crumbles to the dust whenever it comes in contact with the stern realities of life—with the sympathies, the fears, superstitions, and prejudices that make up the soul of human kind. For the future of physic, when we have a statesman born to us, he must be a statesman of the State, and not a statescraft man of our particular craft. . . . Of all professions and liberal callings, ours is the only one that has failed to produce a State Minister. . . . It is so because such of our body as have had the qualities and opportunities have trickled away in the miserable gutter of medical legislation, instead of plunging into the great politics of the nation, and studying the national in preference to the professional welfare. In the future we shall have great statesmen. We had at one time, and for many a year, a man who was as naturally strong as Bismarck, clear-sighted and light-sighted as Palmerston, eloquent as Peel, industrious and bold as Cavour, and who, but for the professional trammels by which he was held down, and the almost mortal professional fights in which he engaged, might have rivalled any of those ministers in fame—a man whose life I will depict in my history, be it only to show what human strength can do, and what ill-judged professional restraint can undo. . . . . The political, however, is only an accidental source of our power; the real source lies in the steady improvement, development, and simplification of medicine as a science and art. A William Harvey—he whose figure, by our sculptor, Durham, this year adorns the capitol of science of the capital of the nation—reformed medicine more than all the medical political preachers that ever lived; and this reference leads me to the leaves of our book that require, not excision, but revision. To begin with simple things, the first act required for the future of physic, is the simplification of the language in which we professionally communicate with ourselves and the world. . . . . Any man, or society of men, or council of many societies, that should set itself to work, in ever so small a way, to bring into use a simple and reasonable scientific language, would do a most important service to physic. . . . .

For the future of physic it is essential to revise our method of receiving and criticising what is brought to light as real or assumed novelty of knowledge. It is a marvel how physic is daily, and with infinite labour, rewritten; still more, how this is criticised. Now the popularity of the literary business, I cannot call it literary art, absorbs every man;] and sedentary force, force developed *in situ*, is, as compared with force *in motu*, all-prevailing . . . . while criticisms have become mere impulses—bastards of love and hate, boldness and fear, adulation and objurgation, industry and ignorance, flux of generosity and flux of selfish conceit. . . . . As a nation, we have a national fatuity for ignoring the history of our own country, and we are the most unpatriotic historians on the face of the earth . . . . . These errors of the Victorian age must be reformed resolutely. Giving due, and even handsome, credit to all fellow-workers wherever they may be, we must become, in England, just to ourselves. For the future of physic, it is essential that some revision be made in the system of training our sons for the work of our profession . . . . . I leave the subject with satisfaction here because of the prospect, clear in view, of two or three great central schools for physic in London, and one or two more in the provinces; with the prospect of professors vying with each other in celebrity, and living by their work; and with the further prospect of students from the remotest parts of the earth trooping to our Asclepian temples, where the light always burns with increasing lustre."

Dr. Richardson next proceeded to speak of the necessity of revising and extending our methods of medical observation by the light, for instance, of the laws of dialysis; of the need of an improved field of research in reference to the functions of the nervous system; the governing power of the sympathetic over the bloodvessels; the molecular changes in nervous structure; the directness of morbid impressions through the expanses of nerves; and of the primary origin of disease by instant change of nervous physical state, in accordance with the recent researches of Dr. Brown-Séquard. Speaking of curers and cures, Dr. Richardson observed:—

"The influence of race on vitality; the estimation of individual and natural life-values, on some more certain method than at the present time is known; the classification of disease geographically . . . are matters demanding inquiry; and as regards the actual cure of disease, what is our prospect touching the task that, between the first natural appearance of the human living thing on the earth to its last natural appearance, it shall not die from unnatural causes, nor from natural causes that come within the governance of man? It is good. It is good because we are learning definitely not to lose trust in remedies for the reason that we cannot apply them at once with accurate judgment, but to believe in them as powerful means of cure that are yet to be accurately employed. . . . Because we are seizing certain agents, and are forcing them to tell us what they perform on the body, what is their physiological action, and what antagonism of action they offer to the phenomena of disease. . . . Because we are learning, in respect to remedies, that their physical action on the process of animal natural dialysis, or action in controlling or exciting nervous systems, may be learned by methods of physical research, that wait but to be tried to be proved as true to us as other physical inquirers." . . .

"In the future of physic, as we advance in the directions I have tried to signalise, we shall stand firmer and fairer with the world. But our success shall not be perfect until yet another, and of all the mightiest, truth breaks upon us—namely, that the solemn and august secret of our power is, not in the amassment of wealth by our professional exertion,—not in the amassment of popularity by it—not even in the creation by it of that future fame and name in history which all men of noble instinct and noble nature would die to secure,—but in the accomplishment by it of one simple end, *the happiness of mankind*. In this accomplishment lies our own happiness, and with it all true and worthy power, all true and lasting glory. Meted out ever for this end, we require no other incentive for research, no other corrective for research, and no other protective against schismatic foes; nay, we require not even reward of gratitude, grateful though that may be when, spontaneously, it flows at our feet. It is a simple formula of living action this; but how potent! Is this professional desire, is this act, is this practice which we daily do, in desire, in act, in practice, is it for the happiness

of the individual, of the race? Shall the conscientious answer be Yes? Then is the act strong, unassailable, and, though it even partake of error, holy. Shall the answer be No? Then is the act weak, easily controverted, bad. This is not moral axiom, it is scientific truth. To many in all time it hath been known, medicine hath lived upon the knowledge; to many it is known now, and medicine is sustained by the knowledge; but in the future *all* must know it; it must be the perennial force hidden in our hearts; our unspoken secret, worthless were it revealed. It must be the bond between ourselves, holding us as brethren in such subtle sympathy that envy shall be an instantly detected deformity, repulsive and retreating. It must be the bond between ourselves and the world, by which the world shall hold to us neither from wonder, nor admiration, nor other doubtful quality of recognition, but from confiding, habitual, abiding trust. Above all, it must be the fountain of our inspiration from the Lord of nature, whose whole scheme and design of creation, however strange it may seem, and to feeble sight devious, is ever toward and for the perfected happiness of his worlds of life."

THE DINNER.

The members of the Association, and some visitors, dined together after the delivery of the address. The chair was occupied by Dr. Richardson. Covers were laid for sixty. Amongst those present were: Admiral Sir E. Belcher, Dr. Lyon Playfair, M.P., Mr. Marmaduke Bell, Mr. Hepworth Dixon, Mr. Prideaux, Q.C., the President of the Medical Society of London (Mr. J. Gay), Dr. Day, of Stafford, Dr. Ramsay, Dr. G. Ross, Dr. O'Connor, Dr. Cleveland, Mr. Frank Richardson, Dr. Thomas Ballard, Dr. Julius Pollock, Dr. Rugg, Dr. Paul, Mr. Dunn, Dr. Hayward, Dr. Day, Dr. Seaton, Dr. Wynn Williams, Dr. Day-Goss, Dr. M'Intyre, Dr. Semple, Mr. Ibbetson, Dr. Wyman, Dr. Bloxam, Dr. Whiteman, Dr. Watson, Mr. Hepburn, Dr. Frank Griffiths, and Dr. Gardiner Hill.

After the usual loyal and other toasts had been duly honoured,

The PRESIDENT proposed "the Houses of Parliament," associating the toast with the name of Dr. Lyon Playfair, M.P.

Dr. LYON PLAYFAIR, in responding, made the following remarks on various subjects connected with medical reform: the subject of medical reform was especially brought before the House of Commons last session. They were aware that the Government had a Bill which dealt with entrance examinations, but did not deal with the reform of the Medical Council. In consequence of this the opponents threw it out. He thought, and still thinks, that this was a mistaken policy. He got from the Government a pledge that if they took their Bill into discussion upon its merits, they would give a Select Committee this year to consider the reform of the Medical Council. Had they done so, the Government would have consented to modifications that would have rendered their Bill efficient, so that in this session they would have secured a second Bill for the reform of the Medical Council. As it is, the reform of that and of the standard for entrances is postponed *sine die*. For anyone who knows the difficulties surrounding such Bills must be convinced that it is impossible for a private member to carry any General Medical Bill through the House. The interests are too conflicting and too powerful to be battled with by anyone not possessing the power of a Government at his back. The Government hitherto have resisted popular representation on the Medical Council, because they view that body as representing the interests of the public at large, and not the interests of the profession. In one sense this is true, but it is not wholly true. If the Medical Council represented the interests of the public only, then the State should pay its expenses, which are considerable. But these are paid, not out of public money, but from a tax levied on entrants into the profession. The public interests ought to be fairly represented by Crown nominees, but surely the profession has a right to direct representation in a body supported by taxes on itself. This right appeared to him to be irresistible, and, he was sure, would have been conceded by a Select Committee. Another advantage would have resulted from this Committee, that it would have arranged the mode of election, so as to render it as little burdensome as possible to the candidates. The general medical constituency would be very large—about three times the constituency represented by himself in the Universities of Edinburgh and St. Andrews. But as experience has shown that such a limited constituency cannot have a contested election without an expenditure of one or two thousand pounds for each candidate, the possible expenditure of an appeal to the whole profession is very serious. It is no good saying that in practice it would not cost much, as a contest for a seat on such a board would not be carried on with the same spirit as for a seat in Parliament. So thought the candidates for the School Board this week, and yet there are few of them who have not spent as much, and some of them more than in a Parliamentary election. He was therefore very anxious that, in arranging the details of election to the Medical Council by a popular constituency, they should not cast an unexpected burden on the medical profession. A Select Committee might have obviated this. Whatever may be the reform of the Medical Council, it need not lose its present representative character of public bodies or of public interests, though it may be strengthened by a direct representation of the profession. He hoped that the Government might still bring in a Bill this session for dealing with the entrance examinations. He fully approved of a one-portal entrance, but thought that the door should be big enough to let in big cats as well as little kittens, and not like the philosopher cut small openings beside already existing big openings. What he meant was this—let the scheme encourage the entrance, by the same door, of giants as well as dwarfs in learning. A single entrance examination must be a minimum examination, one below which no one can enter. But if it qualifies, as it should, for the full exercise of the profession, it will have a tendency to make men aim for a minimum, and neglect a maximum of qualifications. He thought the Universities were quite reasonable in trying to prevent this evil. Why, for example, should a Bachelor of Science, who has passed an examination four or five times higher than that which would be required in the fundamental sciences on the one-portal system, be required to pass another lower examination? Repeated examinations are becoming an intolerable evil in all our educational systems, and are deteriorating real qualifications. He thought that every security should be taken on the one-portal system that no one can pass through it under its minimum, but that encouragement should be given for the acceptance of a maximum in the fundamental science. In the clinical and practical parts of the profession he would make no exception, as that forms the State security that a medical man was fit to exercise his profession. He strongly counselled those who were interested in medical reforms of such importance as the reform of the Medical Council, and the establishment of a one-portal system, to come to some understanding with the Government on these subjects, as it was entirely hopeless to bring them to a successful issue through the agency of any private member, however great might be his personal influence.

The PRESIDENT next gave "Prosperity to our old University." The toast was drunk with three times three.

To the toast of "Literature," Mr. Hepworth Dixon responded.

The remaining toasts included the President and the President for the ensuing year (Dr. Day), the Council and Vice-President, and the Press.

We learn from the report of the Council that the number of members amounted to 506, besides 24 associates, and 38 honorary members. During the year, death had carried off Dr. Uvedale West, Dr. Adamson, Dr. Eves, Dr. Armstrong (Armagh), Dr. Anderson (Glasgow), and Dr. Copland, F.R.S. The alteration proposed by the Association in the existing rule, and by which it is proposed to admit an unlimited number of candidates in each year to pass the degree of M.D., without residence, and subject to the passing of proper examinations, had been brought by the Assessor before the University Court, had been accepted by the Senatus Academicus, approved by the Chancellor, and now only awaited the sanction of Her Majesty in Council to come into force as a new statute. The new officers were elected as follows:—President: Dr. H. Day (Stafford). President of Council: Dr. Richardson, F.R.S. Vice-Presidents: Dr. Black (Chesterfield), Drs. Crisp, Cholmeley, Lockhart Robertson, Seaton, and Wynn Williams. Council in place of those who had gone out of office: Dr. G. Bird, Dr. Brewer, M.P., Dr. Butler (Winchester), Drs. Cooke, Wharton Hood, L. Hanwell, Nicholls, Semple, and Stedman.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 14, 1870.

THE ENGLISH MEDICAL CHARITIES SYSTEM CONTRASTED.

The English Poor-law Association contrasts the English and Irish systems of Poor-law administration with a view to prove that, were we to increase the efficiency and salaries of our Poor-law medical officers in England, we should greatly lessen the pauperism which is so threatening a phenomenon in modern English civilisation. In his recent address, the President of the Association tells us "that in Newcastle-on-Tyne, with a population of 110,968 inhabitants, there are only 8 medical officers, with a total cost of only £853 for medical relief, but a cost of no less than £43,093 for Poor-law expenditure; whilst, in Belfast, with a population of 146,529, there are no less than 18 medical men employed, at a cost of £3,700; but the total Poor-law expenditure is not half that of Newcastle, that is, it is only £22,114 12s. 5d."

Dr. Maunsell, who has paid considerable attention to Poor-law questions, states that, in England, the mean amount of paupers in receipt of out-door relief is 784,906, and of in-door paupers, 157,740. In Ireland, only 50,257 receive out-door relief, and 288,953 in-door relief. He thinks that this is owing to the fact that the vast majority of cases of out-door relief are those of sickness, which, in Ireland, come under medical charity, and, in England, are cases of out-door relief. The cost of each out-door pauper in England is £4 5s., and of the same person in Ireland is £1 per annum. The expenditure for out-door relief in Ireland on the 50,257 paupers was about forty-eight thousand pounds, and for those relieved by the medical charities about one hundred and twenty-four thousand. In England, each in-door pauper costs about £8 10s. a year, and each out-door pauper costs £4 5s.; but the latter are enormously augmented in number by the want of a Medical Charities' Act. In Ireland, the medical charity system enables budding pauperism to be arrested at a cost of only half-a-crown per head per annum; and the rates in Ireland, it seems, are about three shillings in the pound against seven shillings in the pound in England. In Ireland, the receipt of a medical order does not convert the recipient into a pauper. In England it does. In Ireland, it is called *medical relief*, costs half-a-crown a head, and does not demoralise; in England, we call it *out-door relief*, and make people paupers at a cost of £4 5s. a head. Decidedly "they manage these things better in Ireland." There is no law, too, in Ireland to prohibit out-door relief to the able-bodied more than there is in England; and it seems pretty clear that the report of the Poor-law Board recently issued is fallacious, when it states that gratuitous medical attendance would entail "great additional public burdens." The very contrary of this is shown to take place in Ireland.

It seems that, in all Ireland, there are 2,410 medical men, and of them 949, or three-eighths, are Poor-law medical officers. The number of medical men in England and Wales is 10,616. In London, there are 3,228 practitioners of medicine, or one to every thousand inhabitants; in Dublin, the proportion is greater per thousand. There are 7,000 medical men for all England and Wales, excepting London; and, if the numbers of practitioners of the large cities are again subtracted, there are, in all probability, just as few medical men in English rural districts as in Ireland. The consequence of this is, that much of the work in England is done by unqualified assistants. There are only 3,906 Poor-law medical officers in England out of the 10,616 medical men; and, in Ireland, there are 949 out of 2,410. The efficient system of Poor-law medical relief at present existing in Ireland was introduced in 1852; and in that year, according to Dr. Rogers, the gross expenditure or poor relief was £1,099,678, or 1s. 7d. in the pound, including medical relief (then only £54,289). In 1869, the total cost of poor rates was only £817,772, or 1s. 0¼d. in the pound, including medical relief, which was now no less than £124,000 on the medical charities alone.

It is stated that a very large number of cases of out-door relief are those in which the recipient has nothing more than medical relief; and many letters have been written to say that for every pauper requiring relief, the writer attends four or five requiring medical relief only. It is very common, indeed, to have an order for medical attendance on the wife or children, the husband being at work at the time, and receiving no further relief. The services of the Poor-law medical officers are not always strictly limited to the pauper class. These services are sometimes ordered and given to persons who neither require nor receive any further relief,—nay, whom the Board pronounces able to provide additional relief for themselves even in midwifery.

The Poor-law medical officer in England is greatly imposed upon. At the aggregate meeting of medical officers

in June, 1868, the late Dr. Colburne said, "Not only do nearly the whole of the rural labouring population, but labourers in the direct employ of the rich and distinguished, even Cabinet Ministers, peers of the realm, possessors of fabulous wealth, come upon us for themselves or families as patients." The facilities for medical relief to the real poor, however, are not nearly so great as they should be in England and Wales, inasmuch as they are now rendered by medical officers under a galling sense of injustice. In Ireland, the districts are fairly equalised, salaries are much larger and more uniform, all drugs are found, and the dispensary physician can rely, in the performance of his duty, on the support of the Commissioners. In England, salaries are fixed by guardians on no principle whatever, and districts are sometimes so large that no one man can attend to them. With the exception of London and a few large cities, all drugs are found by the medical officers.

Need we wonder that, with all these absurdities, the pauperism of England and Wales should be so extensive, that vaccination should be so ill-carried out, that we are threatened with an epidemic of that loathsome disease, small-pox, in London at this very moment, and that the hearts of our unfortunate brethren of the Poor-law medical service should be full of disgust and sorrow? There never was an agitation which promised more fruits towards the improvement of morality and health among the humble classes in England and Wales than that of Poor-law Medical Reform; and we feel persuaded that if the agitation be kept alive, we shall not be able much longer to say, "they manage these things better in Ireland."

Notes on Current Topics.

About the War and Wounded

We have before mentioned how the war appears to be brutalizing the Germans, who previously had in this country a reputation for gentleness, they are rapidly losing. Some of the stories of cruelty have been called in question, but the following being vouched for by Mr. Bullock, will not be questioned, and it records the murder of a medical man engaged in attending the wounded and sick. Mr. Bullock thus records the death:—"A young French doctor named Lebaude, attached to the International Ambulance at Sedan, having business which took him to Mézières, was avoiding the high road, which is occupied by the German troops, and took to the railway embankment, when a sentinel shot at him and missed. M. Lebaude at once displayed a white handkerchief, but in vain, for a second shot traversed his breast, inflicting a wound, of which he died within twenty-four hours. To a fund being raised to support the poor widow, who is temporarily left destitute, I contributed fifty francs out of a sum committed to me by Dr. Egeling, of the Hague, for the relief of distress in France."

* * *

Last week we recorded the death, from over-work, of Dr. Davis, a coloured physician, who was known to the poor people in the neighbourhood as *le bon docteur noir*, and whose memory will remain, we hope, as long as that of the suffering which developed his character. Dr. Davies was a student of St. Bartholomew's Hospital, London, where he made all his friends. He afterwards graduated at Aberdeen. The Hospital and University may both be proud of him. He was a worthy member of the most exacting profession, ever ready to do all the good he could; and he entered on the mission which put an end to his career, from sheer love to his kind, and the work. How our professional heroes contrast with the tinselled hosts of Mars.

* * *

A discussion was held on the 28th ult., in the Health Section of the Social Science Association, respecting medical organisation in war time. Colonel Lindsay, Sir J. G. Logan and others were present. We should be glad for a full discussion to take place, but we think that military surgeons are those who should chiefly speak. Their views are far more entitled to be heard than those of mere civilians, who take up the subject for a time while it is popular.

* * *

We hear that pyæmia has appeared at Orleans. This is scarcely more than might have been expected. It is also told us that disease is making considerable ravages amongst the German troops round Paris, and in other parts of France. The exposure to the trying weather would be sure to bring about this result.

Increase of Small-Pox.

At the last meeting of the West Derby (Liverpool) Guardians, the governor reported that small-pox is on the increase. There have been two deaths from that disease this week, and there are now twenty-three cases under treatment. Twelve cases of small-pox were admitted for the week ending the 29th November.

Our Glorious Constitution and the Beauties of Representative Government.

How blessed is our lot as great Britishers, and how thankful we should be that "we are not as other men are." Where is the other country where the right man or the right woman are never in the right place? Where is freedom of election so universal and where is its exercise by the happy electors so sensible and admirable? Outer barbarians may be led away by humbug and clap-trap, or meddlesome women, but *we* know better. Witness the School Board elections for Marylebone and Finsbury:—

Miss Garrett first with 47,858 votes; Professor Huxley a very bad second, with 13,494; Mr. Hepworth Dixon all but distanced with 9,031; Mr. B. Lucraft, elected. "Oh! where is wisdom to be found?" The only shop in which the really genuine article can be procured is that of Mr. John Bull, wholesale maker and mender of political constitutions.

Adulteration in New York.

It appears from a statement in the *Food Journal* that New York suffers as much from the evils of adulteration as London. This kind of fraud is largely carried on in the article of sugar-caudy, for mixture with which great quantities of kaoline, or porcelain clay, are annually sent from South Carolina. Fortunately, the imposition is easily detected, the sugar being soluble in water, while the clay remains undissolved. It is hard that the

American youngsters cannot suck their lollipops without having their insides turned into a china shop. A still worse form of adulteration prevails in the article of cream of tartar (tartrate of potash), if, indeed, it can be called adulteration at all, when there is not a trace of cream of tartar to be found in the material sold under this name, which is composed of five-sixths of plaster of Paris, and one-sixth of sulphuric acid and starch.

Co-operation between Doctors and Druggists.

There has long been more than a suspicion that, in London, a very desecrated kind of traffic is daily carried on between *practitioners of a certain grade* and druggists anxious for business, and not very particular how it is got. The mutual advantage accruing is, that the practitioner gets a second fee out of the patient in the shape of a handsome commission on the cost of dispensing his prescriptions, the druggist works his little monopoly at prices which pay both him and his doctor-patron well, and the poor patient is compelled to pay for his medicine double or treble the price for which he would get it better dispensed elsewhere.

A person of the name of Watson Bradshaw, has elaborated this principle to a nicety, and by means of a system of prescribing unheard-of preparations, makes sure that his personal druggist, and none else (but himself), will reap the benefit. His prescriptions are compounds of such *recipes* as "Ext. Nervini," "Acid Eupepiptici," "Ext. Laxative;" and respectable chemists to whom these prescriptions have been brought, have raised a legitimate outcry in the *Pharmaceutical Journal*

Dr. Watson Bradshaw (?) considers that he has a "perfect personal right" to have his prescriptions compounded by his special druggist, and that the matter is "his own private affair." Suppose we agree with him! Will he not allow us the "perfect personal right" to say that the transaction is disreputable and disgraceful to the profession. But we *don't* agree with him. A sick man who pays Dr. Bradshaw for advice gives his money and should, in honesty, get what he buys, unrestricted by any of Mr. Bradshaw's arrangements for a commission. The patient purchases intelligible information, and not unmeaning gibberish, and Dr. Bradshaw has no authority whatever to keep back what he bargains to supply, still less has he any "private personal right" to dodge the patient out of a second fee.

Supposed Impress of an Image by Lightning.

The Coroner for Sandhurst, near Melbourne, Mr. Pounds, publishes in the last number of the *Australian Medical Journal* a case of death by lightning, which appears to have been carefully and accurately observed by him. One of the observations made is very extraordinary, supported as it is by reliable evidence, and by apparent care and calmness in its record. After describing other *post-mortem* appearances he says, "having entirely removed the clothes from the body, notwithstanding the unusual *post-mortem* lividity of the neck and of the skin over the right side of the sternum, we could distinctly see the impression of a young tree of ironbark, in most parts as plainly as if photographed, and in the same sepia tint upon the white skin. Its trunk or stem was quite reversed, commencing at the neck, where the mark of the lightning from the acute angle of the lambdoidal suture at its junction of the sagittal suture, had left the distinct mark described, and extending, as I have stated, across the sternum to the left ilium, leaving upon the breast-skin the impression of the branches and leaves, although reversed, quite perfect and visible to the naked eye, even then some twenty hours after death, when it was fast fading in the increasing lividity of the parts around.

I greatly regretted that every well-informed medical man in my district had not an opportunity of seeing this case, and that I had not known of the existence of that singular phenomenon the previous evening after death, before any discolouration had set in, else I should have endeavoured to have had a photograph taken of deceased's chest. However, having quietly succeeded in taking a rough sketch, I left, and revisited the place of death; and, from the hurried outline sketch I had taken, I found the exact *fac-simile* in a young ironbark tree, growing about twenty feet high, and standing by itself on the opposite side of the road and within some sixty feet of the spot where deceased was killed, and looming as it were between the spot without any interposing objects between it and that part of the open horizon from which, south-west and by south, the storm had come the previous afternoon. I took a rough sketch there of the tree; but, upon re-visiting the place for the purpose of writing this narrative of the facts in so interesting a case, nineteen days after the occurrences, I found much of the tree's foliage had fallen off, as if it had been to such extent affected by the lightning passing above, across, or near it, as to leave its distinct impression upon the body. It remains an interesting subject for inquiry, for which I should like to find an explanation, how, through so much clothing over the body, the figure of the tree could be so mysteriously and so wonderfully impressed with its distinct and perfect form."

The same fact is testified to very unequivocally by Dr. Kieram, the surgeon who made the *post-mortem* examination of the body.

Epidemics and Endemics.

Dr. Arthur Ransome, of Manchester, says, that whilst bronchitis and catarrh, as every one knows, are most common in winter, and diarrhœa in summer, rheumatic fever is a capricious complaint, although rather more frequent in winter than in summer, the disease may come on at any time, but is commonest in autumn. As to scarlatina, it is never entirely absent, and usually is most prevalent in autumn, and least so in dry summer months. Measles is essentially a disease of winter and spring. Whooping-cough, too, is, on the whole, more prevalent in cold than in warm weather. Typhus fever is rare during the frost of winter, and the number of cases is low in early summer. There is little typhoid fever in Manchester, which is ascribed by him to good drainage and water supply.

Sulphurous Acid in Typhoid Fever.

Dr. Wilkes, of Ashford, Kent, affirms that he has had *very great success* in the treatment of typhoid fever by means of small doses of sulphurous acid. He gives the acid with syrup of oranges in water, in doses of from two

and a half to twenty minims every four hours, until the patient complains of tasting, as it were, lucifer matches. He alleges that this remedy arrests the further development of the fever-poison, and thus *exterminates* the fever. "Briefly, it is an antidote." Of 173 cases of typhoid fever treated, only two died, and these two did not take the acid.

Alcoholics Again.

Dr. Parkes has been experimenting with claret on a patient, and finds the injestion of a certain quantity, produces acceleration of the heart's action, but no marked rise of temperature. Ten ounces of the wine contained one ounce of pure alcohol. When the man took twenty ounces, he was flushed and uncomfortable and alcohol began to appear in the urine. This healthy man, Dr. Parkes says, would be better without alcohol, as it increases the heart's action too much, and might lead to alteration in its condition, or to injury to the vessels, if any degeneration in these were to take place.

Skin-Grafting.

This seems to be the pet of the hour of surgery. Dr. Gillespie, at the Royal Infirmary of Edinburgh, in order to heal a surface, the remains of a large callous ulcer, removed recently two pieces of skin about ¼″ in diameter from the upper arm, by raising them up with dressing forceps and cutting them off with scissors. These were placed on the surface of the healthy granulations and retained in position by strips of isinglass plaster. Two days afterwards the patches were found to be adherent, but one soon fell off dead. The other did well, and the ulcer cicatrised on the twenty-third day. In the Clinical Society of London, too, on Nov. 11th, Mr. I. Croft showed a patient who formerly had a sore, six inches by four, on the leg. On August 1st, a piece of skin, 1-11″ in diameter, was snipped from the thigh, and fixed on the sore. On the 22nd, an island of skin was seen, which spread rapidly, and the wound was soon nearly skinned over. Mr. Mason's own experience led him to say, that the size of the grafted pieces should be that of canary seeds. Mr. Arnott had removed the diseased structures in keloid of the neck and transplanted some pieces of cuticle. One piece slipped, but four did well. In the case of a man, who had two sloughing ulcers, which after a time improved, he transferred to one three pieces of cuticle, and left the other alone. These did well, and the sore healed, but the other did nearly as well without them. Mr. Durham mentioned the case of a boy with lupus non-exedens of the face, which he had excised, and loosening some strips of skin at the edges, he turned them in, without destroying their connexions with the cheek. All adhered, and did well, each becoming a centre of cicatrization. Small pieces, he thought, were better than large ones. Mr. Callender mentioned the case of a tertiary ulcer of the leg, on which a graft had taken root and done well.

Memoir of Sir James Simpson.

The Executors of the late Sir J. Y. Simpson are making arrangements for the preparation of a Biography, and request persons possessing interesting letters from him, or interesting information regarding him sending the same to them.

The Irish Union Apothecary.

The Irish Poor-law Commissioners have addressed a long letter on the subject, which is published in the *Journal of the Irish Medical Association*, to the Guardians of the North Dublin Union.

In declining without hesitation to withdraw the order in question, the Commissioners avail themselves of this opportunity to enter into some further explanations regarding it, in addition to what has already been stated in the Circular which accompanied the order, in a letter addressed to them by Messrs. Boileau and Boyd, from which they quote the following passages :—

"The system carried out (in making Poor-law medicine contracts) is so uncommercial and so unbusiness-like, that we feel perfectly sure that were you to be placed in the position of knowing all the facts connected with it, it could not for a moment be sanctioned."

* * * * * *

"We have always when furnishing any price list of medicines drawn special attention to quality, and made allusion to the trade artifices used in the contract system, but all our expostulations with a very few exceptions, have proved unavailing."

The Commissioners entered in 1861 into a correspondence with the Lords Commissioners of Her Majesty's Treasury, having for its object permission to appropriate a small part of the contingent funds of this department, to the appointment and remuneration of professional referees, for the examination of medicines complained of by the medical officers of unions.

At the close of the year 1866, the Commissioners received such a sanction as they could act upon, to the proposed expenditure, and immediately availed themselves of it, by establishing the form of contract now existing, which binds the contractor to take back bad medicines condemned by a professional referee, and replace them with proper ones.

In the course of the few years' experience which the Commissioners have had of the operation of this form of contract, they have obtained several valuable reports of analyses made by Dr. Apjohn of samples of medicines complained of and sent to him for examination.

These examinations have not been without result altogether, medicines condemned on analysis, have been taken back by contractors and replaced, but the punishment, if such it can be called, is wholly inadequate to the offence, and has not had, and is not likely to have, the effect of remedying the evil.

The present order therefore, has resulted from many years' experience of evils, which it has been attempted to contend with in other ways, and owes its existence to no external source, and to no motive but that of desiring to procure good and reliable medicines for the treatment of the poor.

The Commissioners felt in fact that the time had come when they ought to use every power with which they were invested by Parliament, for the remedy of so grave an evil. If the exercise of those powers should fail, they will be in a situation to apply to Parliament for further legislation on the subject.

Mr. Gohaul Chunder Roy.

This gentleman, whose name will be seen in the late lists, is the first Indian who has presented himself for examination for the Fellowship of the Royal College of Surgeons of England.

Disability of Candidates for the office of Poor-law Unions Apothecary.

It has been a subject of some debate amongst the Profession in Dublin, whether a member of the College of Physicians can be a candidate for the office of Poor-law Unions Apothecary.

It had always been understood that the College of Physicians required candidates for its licence to give up their Apothecaries Licence, if they possessed one, and to enter into an obligation not to practise as an Apothecary. We learn that, that restriction has been to a certain extent removed, and holders of its diploma are not now required to surrender their Apothecaries Licence, and, if they have already done so, they are entitled to have it returned to them whenever they claim it.

The College, however, still inhibits its Licentiates from keeping open-shop for the sale of medicines. We are anxious to see whether contracting under Government for the sale of large quantities of medicine is equally objectionable to the College with the dispensing of pills and mixtures to patients.

Snakebite Mortality in India.

The statistics of deaths by snakebite in India are given to the Profession by the *Indian Medical Gazette* in a supplement to its last issue, and they certainly establish a case for the adoption by the Indian Government of some system for the extirpation of venomous snakes. It appears that 11,416 lives were lost last year from this cause, of whom 4,146 were men of adult age. Of these deaths 2,690 are known to have been caused by bites of the cobra; and in nearly 7,000 cases the species of snake was unknown; but, from the proportion of deaths caused by the cobra, it may be assumed that, altogether, at least 5,000 deaths result from the existence of this snake alone.

This terrible mortality indicates a proportion of one death to every ten thousand of the population, and shows that snakebite is one of the most frequent causes of death in India.

The Bishop of Manchester on Female Medicine.

The Women's Rights agitators appear to have made a dangerous mistake in selecting for their Chairman the Bishop of Manchester, who would appear, from his utterances, as their president, to be a man of views too logical, and, as they would say, too antediluvian for their purpose. Instead, therefore, of singing the song set down for him in the programme, in laudation of female progress, he took an unexpected and unwelcome vein, and said as much against the extreme development of the women's rights movements as its most violent opponent could give expression to. The following is his lordship's denouncement:—

"Whilst he welcomed everything that would make the education of women sounder, more deeply cultured, ranging more over the whole of her faculties than he was convinced the education offered to them hitherto had done, he wished to keep distinct the proper functions of the woman and the man in the constitution of modern society; and he could not welcome any attempts by which women sought to intrude upon functions that did not belong to them. When he saw ladies thrusting themselves in all directions into the domains of politics and medicine, he was reminded of the Athenian Council in one of the plays of Aristophanes, where the ladies, presuming to take in hand affairs of state, found that they made a mess of them, and concluded that their duty was to attend to their own business at home. What was wanted was a strengthening of the female character on its true divine foundations. For instance, he, the other day, was in correspondence with a lady who wrote him a very admirable letter on the opening of schools of medicine to women. There were certain departments of medical practice which might with great advantage be committed to women; but if any persons thought that a school of anatomy, attended by mixed classes of male and female students, of from eighteen to twenty-five years of age, was an edifying spectacle in the midst of our modern civilisation, their notions and his were widely different."

The late Dr. Uvedale West.

Dr. Robert Uvedale West, who lately died at the age of sixty, resided of late years at Alford. He was esteemed as one of the most skilful and experienced accoucheurs. He himself attended nearly 5,000 cases of midwifery, and he had contributed to various journals several highly practical and exceedingly valuable papers in this branch of practise.

Vaccinophobia.

When the vaccinophobiacs are doing their best to increase the epidemic of small-pox amongst us, by spreading useless alarm as to the consequences of vaccination, and multiplying ignorant and false assertions, it is pleasant to see an able paper like the *Examiner* take up the subject of vaccination and small-pox in a spirit of inquiry worthy of its columns.

In a capital article last Saturday, the *Examiner* completely disposes of the allegations of the vaccinophobiacs, and if it treats them with far more consideration than they deserve, we hope they may be the more disposed to learn. We have not space at our disposal, or would cite the whole article, which sums up very well what vaccination has done for humanity. The writer says:—

"We have no objection to the matter being fairly discussed over and over again. If such were not the case, the truth of the assertions of vaccinators would soon be forgotten, even by the majority of doctors; but we earnestly maintain that Government is fully justified in compelling parents to vaccinate their children."

We are glad to find that the *Examiner* has on its staff men capable of looking at such questions, and incapable of being deceived by the constant repetition of the ridiculous fancies of fanatics.

Is any one Sane?

It has long been a saying that "one-half the world believes the other half mad," and some of our mad doctors have the credit of never being at a loss to find signs of unsoundness of mind in criminals.

We may in time get a little further, and find all the world mad if we follow the line of the *Pall Mall*, which on Saturday evening, published the following paragraph:—

"An interesting question is raised by the medical officer of Portland prison in his annual report to the Directors of Convict Prisons, which has lately been printed. After mentioning the fact that the feigning of insanity has wonderfully decreased in that prison, of which he is sincerely glad, as it demands in the detection an exercise of great care and judgment, and it is often a long time before the mind can be fully satisfied as to the real or feigned

aspect, he adds, 'it would be an abstract question for psychologists whether a man who can simulate insanity is really at the time perfectly 'mens sana in corpore sano.' This subject is one of great interest, but I could not even attempt to enter upon it within the scope of an annual report. Insanity and crime are, I have no doubt, often very closely allied; and we may hope that psychological science will at some future time be able clearly to define a line of demarcation.' It is to be hoped that psychologists, if they take up this subject, will be very careful what they are about, otherwise they may discover a line of demarcation between sanity and innocence in the ordinary acceptation of the terms. We shut up in prisons people against whom we prove guilt, and should probably shut up in a lunatic asylum any one against whom we could prove innocence; fortunately, even if we suspected a fellow-creature of being thoroughly innocent, it would be difficult to prove it against him. As society is constituted a thoroughly innocent person would, it is to be feared, be so inconvenient that we should be obliged to lock him up in self-defence; even if not violently innocent he would be utterly helpless and useless for all practical purposes. Success in any of the learned professions would be out of the question—as a mechanic he would fall a victim to some Broadhead or be starved by the action of the trade unions. It is an abstract question for psychologists whether a man who can simulate sanity is really at the time 'mens sana in corpore sano,' for there is strong ground for believing that most, if not all of us, are conscious that we are in truth only simulating sanity. We bungle sadly in the attempt as a rule; those who succeed best we call our 'great' men; and it would be satisfactory, considering the important interests with which we trust them, to know that these latter really are sane. The present condition of Europe throws some doubt on the point."

There is to be a dramatic performance at St. George's Hall on the 19th, on behalf of the Middlesex Hospital.

On Saturday the 3rd. inst., Dr. J. Broderick Barbour, was appointed resident medical officer to the Stockwell Fever Hospital by the Metropolitan Asylum Board.

Dr. Lory Marsh will preside at the next dinner of the Medical Club, which will take place on Tuesday, December 20th.

The Liverpool Corporation have requested Professor Huxley to nominate some gentleman to enquire into the causes of the towns present unhealthiness.

Dr. Brewer, M.P., has been elected a member of the Metropolitan Board of Works for the parish of St. George's, Hanover square, in the place of Col. Hogg.

Dr. Thorne Thorne has been to inquire, on behalf of the Privy Council, into the outbreak of fever at Stevington, near Bedford.

Professor Odling, M.B., F.R.S., will on December 27th, 29th, 31st, and January 3rd, 5th, 7th, deliver the customary Christmas Lectures at the Royal Institution, adapted for a juvenile audience, the subject being "On Burning and Unburning."

According to the *Western Morning News*, scarlatina, which is very epidemic in Devonport now, appeared in the *Impregnable* training-ship a short time ago, spreading rapidly amongst the boys, but the staff-surgeon has since written that it has disappeared, and that in all only sixteen boys were attacked, none of the cases being serious.

The next meeting of the Medical Society of London, on December 19, is intended to be a "Clinical Evening," and Dr. Thudichum is expected to give some of his recent clinical experience at the Seat of War.

Every effort is being made fairly to test the working of the Contagious Diseases' Act. Officers commanding at stations where it is in operation, have been directed to render weekly a return of the numbers admitted on, and discharged, from the sick list under the Act.

Several professors of medicine, of the University of Bohn, have been attending the sick and wounded in France, and Drs. Busch and Rindfleisch have obtained the Iron Cross. The number of medical students at Bohn this year is comparatively small, on account of the war.

It is said by Lord Shaftesbury, after a visit to the sick and wounded at Heidelberg, that the care taken of the poor fellows was beautiful to behold, and that the *entente cordiale* is in great force between the French and Germans, who are as cheerful as the day is long.

Dr. Doring, of Vienna, says, that he has found chloral hydrate of very great service in sea-sickness, even in long voyages. This assertion is easily tested in our "beautiful isle of the sea," and chloral hydrate is again on its trial. It has often been tried and failed in our hands in other matters.

A short time ago Mrs. Sands Cox, of Dosthill hall, Tamworth, laid the corner stone of the Church of St. Thomas-in-the-Moor, Birmingham, which is to be erected to the memory of the late eminent surgeon, Mr. Edward T. Cox, of Birmingham, and will be able to contain four hundred persons.

We hear that the Head Lectureship in Experimental Physics, Clifden College, Bristol, worth about £300 a-year, has been conferred on Mr. John Perry, of Belfast, who a short time ago won the Whitworth Scholarship for Ireland, and is also a Gold Medallist of the Queen's University of Ireland.

It has been suggested to the Newington vestry by Dr. Iliff, their medical officer of health, that some of the many railway arches in that parish, should be utilised as mortuaries, and for establishing a public disinfecting apparatus. We heartily agree with him as we consider that both of these necessaries ought to exist in every district.

According to a contemporary, Sir William Fergusson has a notion of forming a national collection of surgical instruments, in connection with the Museum of the College of Surgeons, which will illustrate the progress of Surgery in this country, and also throw light on the various improvements made at times, by which collection exact data may be provided for future comparisons and matters of priority.

The bad sanitary condition of Camelford is very properly called attention to by a correspondent of the *Western Morning News* who says, that low fever prevails to such an extent in that town, that nearly half the houses have been infected. The town-well is said to be contaminated, which is very probable if, as is said, the town drains flow close by it.

A Correspondent of the *North Wales Chronicle* put forward the suggestion, that a "Hospital Sunday" should be instituted for the benefit of the Carnarvonshire and Anglesey Infirmary. It is shown that there are fifteen hundred places of worship in the two counties, and that an average of only £1 from each would increase the infirmary funds by £1,500. We shall be glad to hear of the proposal being executed.

The general health of the troops in the Madras Presidency is considered very satisfactory by last reports. The health of the 21st regiment at Bangalore has greatly improved, as the men have shaken off the malarious fever contracted at Kurrachee. A great number have been invalided to England, and among the remainder relapses of ague are less frequent. The wing of the 76th at Thayetmyo, has also regained its health, the cholera which had infected it severely, having wholly disappeared.

Those of us who are fond of a glass of milk instead of wine or beer, have been rather terrified to hear of late, that we may easily be assailed by typhoid fever on account of our simple tastes. It is too bad that the pursuits of temperance should lead to such calamities. Nature certainly does not care much for us after all.

Dr. Robert Jolly having resigned the office of resident surgeon to Queen's Hospital, Birmingham, after having held it for five years, the students of that institution lately presented him with a handsome testimonial and an address, as a token of their high appreciation of his services and uniform kindness. He has now been appointed assistant-surgeon at the General Hospital.

A meeting of gentlemen interested in scientific education was held on Tuesday night, the 6th inst., at the Royal Institution, Liverpool, and a resolution was passed unanimously, setting forth the advisability of establishing a Science College in that town, the cost of which was estimated at about £50,000 ; and a committee was appointed to take steps with the intention of executing this object.

We are distressed to learn that a court-martial was held at Malta last month, on board H.M.S. Hibernia, to try the acting assistant-surgeon of H.M.S. Royal Oak, for remaining on shore over his leave, returning drunk, and telling a falsehood to the Commander. The first and second charges were proved ; the third was not proved. The prisoner was sentenced to be dismissed the service.

We hear that University College Hospital is about to introduce the use of hot-air and other baths into its hospital practice. This is very sensible. Rheumatism and catarrhs are admirably treated by the Turkish baths, and, although we don't believe much in mercurial and other fumigations, still, they may be tried here as well as in Paris at the hospital of St. Louis.

Dr. Basham has resigned his Lectureship in Medicine at the Medical School of the Westminster Hospital, after a term of office of twenty-two years, Dr. Anstie having been elected in his stead. Dr. Sturges will take the Lectureship in Materia Medica, left vacant by the election of Dr. Anstie ; Dr. J. Lee, of Caius College, Cambridge, will take Dr. Sturges' place, and be the new lecturer in Forensic Medicine.

A joint meeting of the Royal Zoological and Geological Societies will he held in the Museum Building of Trinity College, on Wednesday evening, 14th December, at a quarter-past eight. *Papers for the Evening :*—1. Dr. Frazer, On Primitive Mining Implements found in Iron Ochre, by Major-General Dunne, Queen's County. 2. Rev. Professor Haughton will call the attention of the meeting to the Ancient History and Habits of the Abyssinian or Yahoo Baboons, recently presented to the Zoological Gardens by Viscount Southwell. 3. Professor Traquair, M.D. On Restoration of a Lost Tail in the African Mud-fish (*Protopterus Annectens*). 4. Professor Macalister, On some Points in the Anatomy of the Chimpanzee (*Troglodytes niger*).

We observe with satisfaction that the Irish Medical Association is taking measures to encourage social intercourse and good fellowship amongst its members. At the last meeting of its Council it was resolved on the motion of Dr. Seward — "That for the purpose of making the medical men of Ireland, being members of the Irish Medical Association, more thoroughly acquainted that they should in a social manner meet each other at dinner, at least thrice a year, in addition to the annual June dinner, the charge for each dinner not to exceed ten shillings. That such member of the Irish Medical Association be admitted thereto on his having notified his intention to the Secretary, at least two days previously."

At a meeting of the Pathological Society of London, November 15th, Dr. Silver showed the supra-renal capsules of a man, aged twenty-four, who had died of Addison's disease, and whose skin had been growing dark for two years. The lungs were tolerably healthy ; but both contained masses of *obsolete* tubercle. The supra-renal capsules were adherent, and completely converted into a calcareous mass on each side. Dr. Powell showed specimens of fifteen cases of *post-mortem* examinations of false hæmoptysis. In some specimens, small sacculated aneurisms of the pulmonary artery were found. In one case, there was a thin walled cavity, in a state of active ulceration. Of the fifteen cases of fatal hæmoptysis, twelve had occurred from rupture of the pulmonary artery in a cavity ; preceded in eleven, by dilatation, and in one, by ulcerative erosion. Dr. Murchison and other Fellows related cases of rupture of the stomach occurring from railway accidents, &c. Dr. Whipman showed a morbid specimen of diseased tricuspid valves. The patient had showed symptoms of pneumonia and hæmoptysis. The tricuspid valve was ulcerated, and one of its *cordiæ tendinæ* torn. Dr. Kelly showed the heart of a child, aged three months, which had suffered from cyanosis. The pulmonary artery arose from the left ventricle, and the aorta from the right. The only communication was through the patent foramen ovale. The diretus arterious was closed. The child was not cyanotic until five weeks after birth ; it then became rather livid, and a loud systolic bruit could be heard nearly over the thorax, most distinctly at the apex. In another case, shown by the same gentleman, from a child aged six, who died in hospital, of renal dropsy, after scarlatina, there had been only a systolic bruit heard during life between base and apex of the heart. The septum between the ventricles was here defective above, so there was an oval communication between right auricle and the two ventricles. Mr.

J. D. Hill showed a specimen of a tumour he had just removed, which was adherent to the under surface and costa of the scapula of a patent in the Royal Free Hospital.

SCOTLAND.

UNIVERSITY OF EDINBURGH.—It is understood that Government intends giving an annual grant of £200 towards the endowment of a Chair of Geology. This, in addition to the endowment made by Sir Roderick Murchison, will yield, it is estimated, about £700 a year.

MEDICO-CHIRURGICAL SOCIETY.—Office-bearers for the ensuing year :—President—Professor Bennett. Vice-Presidents :—Dr. Thomas Keith, Dr. Matthews Duncan, Prof. Lister. Councillors :—Dr. Thomas R. Fraser, Dr. J. D. Brakenridge, Dr. A. G. Miller, Dr. Angus Macdonald, Dr. James Fraser, Dr. Chiene, Dr. C. H. Groves, Dr. Wyllie. Treasurer :—Dr. George W. Balfour. Secretaries :—Dr. Argyll Robertson, 48 Queen street ; Dr. Claud Muirhead, 7 Heriot row.

ROYAL SOCIETY OF EDINBURGH.

SIMPSON AND SYME.

AT the opening of the Session 1870-71, M. D. Milne-Home LL.D. Vice-president, delivered an able address, in the course of which he noticed the deaths of Fellows of the Society in the past year, dwelling naturally upon those of Professors Simpson and Syme.

Professor CHRISTISON, in proposing a vote of thanks to Mr. Milne-Home for his address, alluded to the notice that had been given of Sir James Simpson. As to the discovery of chloroform, he said the history of that had never yet been fully given. When fully given, it would constitute one of the most curious instances he knew of the gradual progress of discovery. There was one link which he thought, in justice to Sir William Lawrence, he should supply, as he could do it authoritatively. Sir William Lawrence, in the summer of 1847—the same year in the November of which Sir James Simpson made his great discovery—did repeatedly employ a solution of chloroform in rectified spirit as an anæsthetic in his surgical practice, and ascertained that it was a superior agent to sulphuric ether. Had Sir William possessed that knowledge of chemistry which Sir James Simpson very properly held that every medical man should possess, he thought there was a strong probability that he would have anticipated Sir James in his great discovery. But the article had come to him recommended by the very absurd name of chloric ether. He (Dr. Christison) rather believed there was no such thing as chloric ether known ; nevertheless there was an article which had been so called. It was recommended to Sir W. Lawrence under that name ; it was tried under that name ; and he was informed that both Sir William and his assistant saw that something more concentrated was wanted, and that they were busy considering how they might concentrate it when suddenly the discovery of Sir James Simpson came forth and put an end to their enquiries. Had they been aware that the substance in their hands was nothing else than a solution of chloroform in rectified spirit, the solution of their problem would have been very simple indeed. In giving some reminiscences of Professor Syme, Dr. Christison said that the reason why that eminent man returned from London was not disappointment in regard to practice. His practice during the short time he was in London was a great success. His reason for returning was, that he found himself uncomfortably circumstanced in several respects, particularly as a teacher in University College. He was finally determined to leave the metropolis by his having been present when two of his colleagues were grossly insulted by the students at a great public meeting, and not the slightest attempt made by the Council then present, with Lord Brougham, their Chancellor, at their head, to defend those professors from the insolence to which they were subjected.

Lord NEAVES, in seconding the motion, gave some of his early recollections of Professor Syme. One was a reminiscence of the High School, where they were schoolfellows. The question was put one day, what was the meaning of *puto* a verb which in the ordinary sense meant "to think." Young Syme seemed to be the only lad who knew that in a primary sense *puto* meant "to lop," and he illustrated that meaning by citing the derivative *amputo*, which might perhaps be supposed to indicate the bent of his mind, even at that early age, towards surgical pursuits.

SPECIAL CORRESPONDENCE.

MEDICAL MATTERS AT ROME.

(FROM OUR SPECIAL CORRESPONDENT.)

ROME, *Nov. 30th.*

Do not reproach me, my dear Editor, that I have not fulfilled for so long a time my promise to write for the MEDICAL PRESS. Since I had the pleasure of such long conversations with you in this Italy, of which our Rome is now the capital, I have been so occupied that you can scarcely imagine what my life has been. Fatigues—work—excitement. Fatigues—work—excitement. The great events that have consummated our freedom have left me no time for food and sleep, and all my private affairs are neglected now. Still, I turn back to the thought of the days when we predicted all things—when I hoped for my country, and you expressed a livelier love for Rome than your phlegmatic countrymen generally do. So few of them will take the trouble to learn our beautiful Italian. Why do you not inspire them with your zeal ? We are moving now, and medical science will not be behind, since we have freedom and all we want.

Politically, things go on as well as one can wish. The Pope will not go away, and time will do everything for us. Some think he is not free. It is false. We take no advantage. I can assure you he is as free as you are in London itself. His letters are free to come to the Vatican and go to where he likes. But our finances are our only difficulty, and of course you know our populations are not educated to public life, and that is a curse for us enlightened people. But *pazienza*. We will educate them all.

The hospitals of Rome are placed under the direction of Dr. de Pantaleoni. You must remember he was exiled from Rome by the Pope, and practised, then, some years at Nice, always waiting his opportunity to return. As soon as Rome became our capital, he returned, and the Ministry made him Inspector of the hospitals, where he has been working with his Roman zeal and patriotism, and will soon have everything in order. He will make the great, old hospital, you remember so well, of Santo Spirito the chief, and all the others dependencies. Perhaps, San Rono will retain more privileges than some. The Lunatic Asylum will be distinct. I will send you, my dear editor, and old friend, more letters for your esteemed PRESS AND CIRCULAR, to tell you what we shall do with the Medical School, the University, &c., and what is being done in practice.

You should have heard our *confrère*, Pantaleoni, address the Romans. It would have pleased such an Englishman —lover of Italy and most of all of Rome. But I should tell you, now, that he will not give up medical practice on account of official work and political excitement. He has already taken a house, and sees patients regularly. You know how well he speaks English, as well as German and French—so that Italians as well as English, like you, are linguists too. He has already many patients, and his old English clients are sure to come back to him, now that Rome will be more safe than so many winter stations. I hope to report a good season here, notwithstanding the fright of foreigners at first. But confidence now returns.

AUSTRIAN MEDICINE.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *November*, 1870.

YESTERDAY, there was a rumour everywhere that the Counsellor of the Court, Professor Skoda, will resign his post ; alas, this rumour was confirmed after inquiries.

The state of his health, his advanced age—he is to-day sixty-five years old—are the motives which compelled this star of first rank on the brilliant horizon of the University of Vienna to this resolution. The fatigues, caused by teaching and examining, are too great for the man who has already enough painful days on account of his chronic rheumatism; and if Skoda, also, will no longer be a Professor, he remains, as long as he lives, the light for medical life in Austria—one of the founders of the medical school of Vienna—one of its pre-eminent talents.

Not a very long time ago, the Turkish Government begged the Austrian Ministry to send a great quantity of military physicians, who will receive from 300 to 500 francs a month and the rank of major. Because they desire a large quantity it seems they will make a total reform of the sanitary system; also general civilisation and humanity will get a great profit. The first transport of Austrian military physicians has already reached Constantinople.

Studies and Experiences on the Function of the Prostate. By Dr. B. Krauss.

This author concludes that—1. The seminal fluid is colourless and odourless, and similar to fresh honey (like we find in the cellules of the wax), *as long as* this liquid is contained in *the testicles* and all the ducts; the reaction is alkaline.

2. It is only on the road, after its leaving the duct, that it receives the white colour and the peculiar smell.

3. *During its passing through the prostatic part of the urethra*, the prostate gives away its fluid, colours the semen white, and causes its coagulability in open air. Its reaction is alkaline. The semen extracted from the vesiculæ seminales does not coagulate in open air, but remains clear and without colour and smell.

4. The spermatic animalcules *do not* live without prostatic fluid in the mucous membrane of the uterus of mammalia; but with the prostatic fluid they live a long time in the mucous of the uterus, sometimes more than thirty-six hours.

Conclusion.—The succus prostaticus exercises a positive influence on the faculty of life of the spermatic animalcules, and keeps it up; if by the mucus, excreted by the membrane of the uterus, the faculty of life of the spermatic animalcules is in danger.

All these experiments have been made with the greatest precaution, but only on animals, which have prostates. Next Dr. Krauss proposes to proceed to the genera of animals without prostates.

Summary of Pharmacy.

By Chas. R. C. TICHBORNE, F.C.S., M.R.I.A.,
Mem. Counc. Royal Geological Society of Ireland, Chemist to the Apothecaries' Hall of Ireland, &c.

SYRUP OF IODIDE OF CALCIUM.

M. Ottsmar Eberbach in a communication published in the *American Journal of Pharmacy*, draws attention to the fact, that what is sold in America under the name of iodide of lime, is but a mechanical mixture of iodine and quicklime, containing iodide of calcium, iodate of calcium "iodate of oxide of calcium." He gives a formula for the preparation of pure iodide of calcium, which does not differ from the usual method of preparing iodides of the alkalies and alkaline earths, and which, as it is not likely to give a stable salt, is not necessary to give here.

He then gives a formula for the preparation of the syrup, which may be of use to the pharmacist, and is probably the only method by which iodide of calcium could be made available for internal administration.

It is as follows,

Take of Iodine, 4 oz.;
Iron-wire, 7½ drams.;
Distilled water, 9·8.;
Milk of lime (fresh), a sufficient quantity.;
Sugar, 28 oz.;
Simple syrup, a sufficient quantity.

Mix three ounces of the iodine with the iron, and four ounces of water, in a thin flask with a long neck, shake occasionally, until the reaction has ceased, and the solution assumes a pale green colour, filter the solution, and add the remainder of the iodine, heat to the boiling point, and add milk of lime, until all the iron is precipitated, filter and wash the precipitate with hot water, until all the iodide is washed out, then bring the whole to the measure of twenty ounces, and add the sugar, dissolve by a gentle heat, and add to the solution enough simple syrup to make it measure forty ounces, mix thoroughly and fill into two-ounce bottles well corked. The syrup is a transparent, colourless liquid, which does not tinge starch paper blue. From the directions given to fill into two-ounce bottles, we presume that the author has found that there is a limit as regards its keeping properties, and probably the use of a slight excess of lime water would add to its stability. Some of these easily decomposed iodides of the alkaline earths, might be found more active than the alkaline iodides.

ON THE ADULTERATION OF SAFFRON.

Mr. Daniel Hanbury in a paper on Saffon, published in the *Pharmaceutical Journal*, says that there is no method of testing saffron more effectual than that of scattering a very small pinch on the surface of a glass of warm water. The stigma of the saffron crocus immediately expands, and exhibits a form so characteristic, that it cannot be confounded with the florets of safflower, marygold or arnica, or with the stamens of crocus; saffron is frequently adulterated with carbonate of lime. The method of testing for earthy adulterations, is to place upon a watch glass about a grain of the saffron, and drop upon it eight or ten drops of water, lightly touch the saffron with the tip of the finger, so as to cause the water to wet it. If the drug is free from earthy matter, a clear bright yellow solution will be immediately obtained. If adulterated, a white powder will instantly separate, causing the water to appear turbid.

SYRUP OF IPECACUANHA.

The *Chicago Pharmacist* contains the following formula by Mr. Sale. The author says that this syrup will keep.

℞ Fluid Ext. of Ipecacuanha (U.S.), f. ℥xviijs.;
Sugar, ℥xxxij.;
Water, f. xij.

Pour the fluid extract on the sugar in a shallow evaporating vessel, and set aside in a warm place to dry, when dry add the water, dissolve the sugar with the aid of a gentle heat, and strain. The following, we find, is the formula for the syrup given in the United States "Pharmacopœia." The syrup is said by Parrish to be the most useful and popular expectorant in use in Philadelphia, although it is not a strong preparation. Take of ipecacuanha in coarse powder an ounce; diluted alcohol, a pint; sugar, 2½ pounds; macerate the root in the alcohol for fourteen days, and filter, evaporate the filtered liquor to six fluid ounces, again filter, and add sufficient water to make the liquor measure a pint. Lastly, add the sugar and proceed in the usual manner.

PRESERVATION OF MEDICINES LIABLE TO DETERIORATION.

The *American Journal of Pharmacy* mentions a method of preserving preparations, which is more ingenious, than it is likely to become useful. The aqueous extract it is wished to preserve, is evaporated to a syrupy consistence, and this is absorbed by a previously washed and dried sand, and the whole is exsiccated at a gentle heat. By weighing the dry mass, the proper proportion and quantity, corresponding to each ounce of tincture, may be easily ascertained. From this the tincture or infusion can be readily extracted, by stirring the required weight with a corresponding quantity of water and by decanting, or filtering, if necessary.

THE ETHYLATES AS CAUSTICS.

When one atom of the hydrogen of alcohol is replaced by an atom of potassium, or sodium, the respective ethylates are obtained as crystalline compounds. When placed in contact with the body, they gradually pick up moisture from the tissues, and caustic potash, or soda, as the case may be, is formed from the decomposition of the ethylate. Dr. Richardson proposes these ethylates as local caustics. The ethylates may be dissolved in alcohol without decomposition, and may be applied with a glass brush, or injected by a needle. The ethylate of potassium is the most active. Dr. Richardson says "they will be useful in cancer," or "in cases of mucous and other simple growths, they will be invaluable."

DICHLORACETIC ACID AS A CAUSTIC.

THIS acid is produced by the direct action of chlorine upon glacial acetic acid. It has the composition $C_2 HB^2 \left\{ \begin{matrix} O \\ H \end{matrix} \right\} O$. It is said to be the best cautery for warts known. It is applied on the point of a stopper made for the purpose, and great caution must be observed not to use too much, as it will eat a deep hole into the flesh. One application is frequently sufficient to draw away a wart.

HOFFMAN'S TEST FOR CHLOROFORM.

THIS test, says the foreign correspondent of the *Chemical News* is based upon the fact, that when chloroform is mixed with aniline, and an alcoholic solution of caustic soda, a very strong reaction takes place, and isonitrite is generated, which is readily recognized by its peculiar characteristic smell. This reaction is so delicate that when one part of chloroform is mixed with from 500 to 600 parts of alcohol, the first named substance is readily detected.

Literature.

MAURIAC'S COMMENTS ON WEST. *

It is the fashion among a good number of our fraternity in London to speak slightingly of the French School of Medicine in Paris. It is alleged that there is a want of erudition in the works of the modern French physicians and surgeons, and that they scarcely ever read any work in medicine published in any foreign language. Such criticisms are, of course, shallow in the extreme. The recent works of Lancereaux on syphilis; of Hérard and Cornil on consumption; and many others we could cite are a clear proof how industrious our French brethren are in collecting materials from all sides. But the work before us is of itself quite a sufficient proof that it is not in Germany alone that there are patient and learned physicians, ready and willing to correct their own national acquisitions, by borrowing from every foreign source the glorious lights of science. We cannot help at the very outset of our criticism of this splendidly edited volume, bearing testimony to the immense labour and profound research which the author, Dr. Mauriac, must have brought to task before him, in translating the work of the obstetrician of St. Bartholomew's Hospital. Take it in its entirety, we do not think that any work on the diseases of our sister-sex can for a long time, at any rate, venture to compete with this translation of Dr. West's work; and for this reason—We believe that that work is the soundest treatise on this subject in the English language, and this translation before us contains numerous and admirably lucid treatises on numerous points which, added to the text of this work itself, almost exhaust the subject, and render it difficult for any future writer to discover many new truths.

In the preface to the work, we find it truly stated that the art of obstetrics and the subject of diseases of women have had a good deal to contend against in England, from the "dignity" absurdities of the College of Physicians and Surgeons in London. The translation assures us that such intolerance has happily had no parallel example in France. It seems that every one was astonished when the College of Physicians of London confided to a physician accoucheur of St. Bartholomew's the task of delivering the Croonian Lectures in 1856. At this epoch, in England, as Dr. de Mauriac truly says, and even in France, ideas upon female disease were ruled over by the doctrine which Dr. H. Bennet had made his own, by propagating and defending it with ardour and talent. "At Paris, where he had been an interne des hopitaux, Dr. Bennet had become permeated by the ideas of Broussais." But the inflammatory process did not generalize itself, according to Dr. Bennet, through all the constituent parts of the genital apparatus in women. It did not attack, according to the innumerable pathogenic conditions which engender diseases of the uterus, at one time the body of womb, at another the peritoneum, at another the ovaries of the F. tubes. No, it always concentrated itself in the neck of the womb. The os tincæ, the cervical mucous membrane, became a kind of morbid focus, whence everything radiated. Ulceration of the orifice, general or partial, hypertrophies of the uterine tissue, displacements, the fluxes, the sympathetic disorders of the functions far off, &c., all had all their starting point in inflammation of the neck of the womb. Exclusiveness as to the process, and as to the localization, constituted the double error in Dr. Benuet's doctrine.

This doctrine and its consequences were assailed by Dr. West in his Croonian Lectures, and Dr. Mauriac thinks that the position maintained by Dr. Bennet was broken down, and has not since been able to raise itself again. "But (he observes) we must remark the method of cauterization of the neck of the womb, which resulted from the theory, has resisted longer than the purely speculative side of the question. The theory has vanished, and yet persons have not the less continued burning, without distinction, all ulcerations of the uterine neck, and often with very energetic caustics. It is not to be doubted that by this method, blindly applied, many practitioners create diseases of the womb in persons who were free from any such, and aggravate, or perpetuate indefinitely, insignificant lesions which would have got well if let alone." Dr. Mauriac thinks that the neck of the uterus has had much to suffer from the discovery of the speculum. For instance, Lisfranc, it seems, used to amputate annually about fifteen uterine necks, at the height of his fame. Afterwards he relented in his surgical ardours. To this succeeded the *regimé* of cautery, and few patients escaped the caustic potash, or red hot cautery, or, at any rate, the nitrate of silver. Dr. West's work has contributed to change all of this "heroism." Aran, the respected master of Dr. Mauriac, never ceased to assert that disease of the uterus ought not to leave the domain of medicine. In order to avoid causing patients undergoing great danger, it was necessary, he maintained, to reduce surgical intervention to the most simple and elementary proportions. Dr. Bernutz, as well as Dr. Aran, contributed to this progress, by counselling abstention from all violent therapeutics in a great number of uterine affections.

Another admirable part of Dr. West's lectures is that in which he combats the tendency towards considering displacement of the uterus as the cause of most of the morbid phenomena of the organ. "France (says Dr. Mauriac), I regret to say, accepted more freely than our neighbours across the channel the disastrous therapeutic consequences of the doctrine of uterine displacements. We might have imagined ourselves to exist in the palmy days of iatromechanics. There was nothing thought of but redressors, levers, sounds, pessaries, and engines of all kinds and shape. They treated the uterus with as little consideration as if it were an inert body."

Then, again, "The American Gynæcological School, recently imported amongst us, appears to push us into the path of adventurous experiments. It might take the word *auda city* as its motto. But audacity does not always succeed: it does not, besides, justify, above all, certain practices which will never be acclimatized, I hope, in France, spite of the favours which is there sometimes accorded to strange notions. I allude to certain new therapeutic methods, and, to give an example, to the treatment of dysmenorrhœa by Dr. Marion Sims. According to him, *all* dysmenorrhœas are mechanical, that is, they arrive after some morbid process which results in obstruction of the cervical canal. Such a way of looking at the question, conducts us logically to a surgical treatment. Now, we must not suppose that such treatment is a slight affair. No less is contemplated than incising extensively the neck of the womb in its whole thickness, in order that it may

* Leçons sur les Maladies des Femmes, par le Dr. Ch. West, traduites de l'Anglais, sur la troisième édition, et considerablement annotées, par Charles Mauriac, Médecin de l'Hôpital du Midi, Paris. F. Savy, Libraire-editeur. 1870. Pp. 857.

give free passage to menstruation, and to the spermatazooids. For many reasons, which it would be superfluous to develop here, I blame this operation. I believe that it rarely indicated, always uncertain, and often dangerous. I have chosen it in order to point out whether false or exclusive pathological doctrines may lead us. Well, in the work of Dr. Marion Sims, where there are excellent ideas and the reading of which is very interesting, I have seen with regret a formed determination to treat all uterine diseases by surgical procedures. I hope such a school may make but a few converts amongst us. Let us take from him what is good, but let us not depart from the grand tradition of pathogenesis and therapeutics of French gynæcology."

These excellent remarks by the translator will be perhaps the best proof to English readers how sound the other views held by Dr. Mauriac on diseases of women are likely to be. We might, indeed, expect much from that gentleman when we consider the immense opportunities for clinical observation he has had at his command. For years attached as assistant to Dr. Aran, and then as physician to a special hospital in Paris for women, and now physician to the famous Hôpital du Midi of Paris, Dr. Mauriac would, indeed, have neglected his opportunities, had he failed to become well acquainted with the subject matter on which he writes in Dr. West's book. This work is no mere translation of Dr. West's work. The translator has wished to annotate with the greatest care the *Lectures on the Diseases of Women*. All the points of internal pathology, which seemed obscure or controverted, have been, on the part of Dr. Mauriac, the object of an attentive study, and he has devoted to them detailed notes, some of which are of the nature of memoirs. He has placed under contribution many original doctrines published on diseases of women, not only in France, but in other countries, since the publication of the third edition of Dr. West's work. It results from this considerable labour of the translator, that the *Leçons* form a volume in which the element which is personal to the translator amounts at least to one-third of the whole in extent. Thus, at page 49, there is an admirable essay on the influence of climate and race on menstruation. At page 131 we have the following note: —"According to Aran, persons have much exaggerated the pathogenetic effect of sexual relations in uterine affections. In fact, it results from his statistical researches, that, except in cases of pregnancy or childbirth, affections of the womb are not very common in the first years of marriage, and that we should not estimate at more than one per cent. the cypher of the diseases produced directly by sexual relations, relatively to the total number of diseases of the womb or its surroundings met with in practice. Nothing appeared to Aran to justify what has been said as to the injurious influence of these sexual approaches, which the fear of having children renders incomplete. Persons have also exaggerated the injurious effect of sexual relations practised during the menstrual times. It is the same with masturbation. 'I recently saw perish (said Arran) of acute phthisis, a beautiful young girl, after frightful excesses of this habit. Almost on her death bed, she gave herself up with fury to this horrible tendency, and yet her uterus, as well as the attached organs, were very slightly developed, perfectly healthy, excepting a little catarrh on the neck.' But, if sexual relations only act slightly as producers of uterine affections, when the latter are once produced, they aggravate them, make them relapse, or prolong them indefinitely. Lastly, they may arrest or retard uterine involution, if they take place at an epoch too near the child-birth."

At page 183 there is an admirable note on hyperæmia of the uterus; and, at page 198, a lucid description of venereal ulcers of the neck of the womb. Again, at page 471, there is a complete treatise, headed *On Epithelial Tumours of the Womb*, giving the latest facts on the pathology of uterine cancer. Then comes in page 555 an excellent memoir on inflammation of the ovary and tubes and on pelvic peritonitis up to the last moment, as a scientific treatise. There is then an excellent classification of ovarian cysts, and at page 705 a most complete analysis of the success from operations in removing ovarian cysts. Two of the best notes on this work are upon *Syphilis in Women*, and on leucorrhœa and gonorrhœa in the female. Both of these should be studied by all who take an interest, and who does not, in obscure points in virulent diseases. In conclusion, we think that all who see this shapely volume will thank the publisher, M. Savy, for the extreme care he has taken in the choice of the paper, quite English in its character, and of the types. The printing is excellent, and the whole work does credit to the medical school of Paris, and to the printers and publishers of that paragon among modern cities.

Gleanings.

Amputation by the Combination Plan.

(*With Diagrams.*)

In the last number of the *Boston Medical and Surgical Journal*, Dr. A. T. Hudson gives some very interesting details of this operation as performed by him during the civil war in America, which possess peculiar interest at the present time. In order, therefore, that our readers may the better follow the operation, we present them with the diagrams which were drawn and engraved specially for this purpose.

The author asks, is not the "method of cutting" one prominent question to be discussed? How shall we know when we have enough, and not too much, except by some "method of cutting?" We answer, a definite rule to secure this end, without mistake or failure, is reached by the combination plan. This plan fell to me to work out while in the United States service, a few years ago, and only now fully described.

The amputations made in the First Division of the Fifteenth Army Corps, following the assault on Vicksburg, and the taking of Arkansas Post, were by the circular, by transfixion, and antero-posterior flaps, as generally made. The results, thereof, were often so troublesome, vexatious, and unsatisfactory, we resolved on a new method. Erichsen gave a hint to compromise between the circular and that of transfixion, wherein is combined the advantages of both, without their defects.

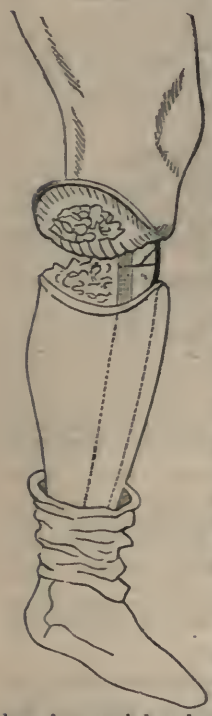
The first case operated on by the combination method, was a soldier in the Fourth Iowa Volunteers, in December, 1863, at the foot of Lookout Mountain, near Chattanooga, Tenn. Amputation below the knee as follows:—

With a scalpel or cartilage knife, an incision is commenced at the posterior side of the leg, and carried in a downward semi-circular sweep, to the crest of the tibia, just through the integument. The lowest deflection of the sweep is nearer the posterior leg. The same cut, beginning and terminating as before on the opposite side, completed, the skin is then retracted as in the circular operation, which lays bare the muscles for the space of an inch. (See Fig. 1). Then transfix the inner side and cut outward, as in other flap operations, dividing the muscles an inch shorter than the retracted integument. The scalpel or cartilage knife is used to divide the muscles on the fibular side. The saw is now applied at an angle of forty-five degrees, and a diagonal cut

Fig. 1.

made three-fourths of an inch deep; when the direction of the saw is changed, and the bones and wedge-shape chip are severed together by a transverse cut. (See Fig. 2).

Fig 2.



Removal of the wedge shape chip from the spine of tibia stump, also removes an old objection, viz., the danger of the sharp bone cutting through the thin integument by ulceration. The flaps thus obtained make a fine, smooth and conical stump, without any crowding or stretching, and without redundance. They are of equal size. The surgeon is not puzzled with the task of trying to fit a four-inch flap to a six or eight-inch fellow. This plan presents many advantages over every other "method of cutting the flaps.'

1. The avoidance of all after-trimming.

2. Quicker and more certain union by first intention.

3. Drainage is complete, and pockets of ichor and pus avoided.

4. The stump presents no puckering or pouting corners.

The operation proved so superior and satisfactory in the above case that it was adopted by several surgeons in our division of the army thereafter, for all amputations of leg, thigh and arm.

In all cases the stump is traversed by the cicatrix. Dr. Smith, and others, object to this result on the ground that it is "not firm and resisting, and not adapted to take direct support." This is a groundless fear, and has been long a bugbear, and innocent obstacle to the work of the surgeon; for direct pressure on the stump is never borne and never allowed. All successful leg makers permit no floor for the stump to touch or rest on; but support the entire weight of the body by the sides of stump, the condyles of the knee, and the tuberosity of the ischium.

In a cavalry boy at Kenesaw Mountain, Ga., in January 1864, whose leg was amputated by the above method in the lower third of the femur, it became necessary to reopen the stump to secure a bleeding artery, twenty-four hours after the operation. It was gratifying to witness how promptly the flaps had become glued together in initiatory union, requiring considerable force to separate them.

Sir. Wm. Fergusson speaks of a similar operation, as the "compromise," and thinks it appropriate for the thigh and arm. But he *transfixes* the integument and cuts the deeper parts by the circular sweep. He therefore does not describe or follow our plan, which we believe suited to nearly all amputations; and when below the knee, it is infinitely superior to all others.

Action of Thebaia.

Professor C. Falk has communicated in ("Deutsche Klinik," 1869-70) the results of his experiments with this alkaloid. Doses of one grain and a-half proved fatal to dogs and cats when injected subcutaneously. The symptoms resembled very much those produced by strychnine and brucia. In strength it was about equal to the latter.

Medical News.

Royal College of Physicians of London.—On the 6th inst., the following gentleman passed the first professional examination:— John Bartholomew Giles Gidley Moore, St. George's Hospital, S.W.

Royal College of Surgeons of England.—At a meeting of the Council held on Thursday last, the following members, having passed the required examinations on the 23rd, 24th, and 25th of November, were duly admitted Fellows of the Royal College of Surgeons of England, viz.:—Edward Mason Wrench, L.S.A., of Baslow, near Chesterfield, diploma of membership dated July, 1854; Frederic Edward Manby, L.S.A., of King street, Wolverhampton, January, 1866; William Stanger, L.S.A., of Nottingham, January 1867; William Bartlett Delby, M.B. Cantab., of Sackville street, May 1867; James Ryall Rouch, L.R.C.P., London, of Norfolk street, Strand, May, 1868; Edward Nettleship, L.S.A., of Finsbury pavement, November 1868; and Gopaul Chunder Roy, licentiate in medicine and surgery, Calcutta, of Calcutta, May, 1870. Four other candidates were examined, but not approved.—The following members were admitted fellows of the college by election, on the 8th inst., viz.:—Peter Marshall, L.S.A., of Bedford square, and John Emilius Mayer, of Her Majesty's Indian army.

University of Cambridge.—At a court of examination held on Thursday last, the following gentlemen obtained the degree of *Bachelors of Medicine*.—Francis Edward Image, Trinity; Charles Edward Underhill, Caius; Lyttleton Stewart Winslow, Downing.

University of London.—The following is a list of candidates who passed at the recent examination for the M.D.—Bryan Holme Allen, University College; Evan Buchanan Baxter, King's College; John De Liefde, Guy's Hospital; Ethelrid Dessé, University College; William Richard Gowers (Gold Medal), University College; John Grimes, B.Sc., King's College; John Harward Hooper, M.S., St. Thomas's Hospital; Henry Franklin Parsons, St. Mary's Hospital; Edwin Rayner, B.A., University College, and Paris; Frederick Thomas Roberts, B.Sc., University College; Frederick Taylor, Guy's Hospital.

The cultivation of Cinchona in Java.—Prof. Hasskarl reports that the weather, on the whole, has been favourable, and the growth of the plants leaves nothing to be desired. The number of plants grown from seeds and layers is upwards of one and a half millions, by far the greater number belonging to the species *C. calisaya*, a good many to *C. officinalis* and *succirubra*, and a very few to *C. lancifolia* and *micrantha*. In addition to these, 870,000 plants have been transplanted, and the whole shows an increase of nearly 200,000 plants since the commencement of the year. 460 kilogrammes of the dry bark were sent to Holland in December,, 1869, and sold at from two to three florins per kil.; 900 kilogrammes have since been exported, and more than 1,000 were ready at the date of the despatch. *Nature* says Prof. Hasskarl reckons the total produce of 1870 at no less than 4,000 kilogrammes of dry bark for exportation, besides some hundreds for home use in the island. An important branch of industry in the colony is now formed by the stripping, cutting, drying, sorting, and packing of the Cinchona.

Bequests to Medical Charities.—By the will of the late Thomas Thornton, Esq., of Brixton, each of the following Institutions receive the sum of £200. London Orthopædic Hospital. Hospital for Incurables, Hospital for Diseases of the Chest, Victoria Park, City Truss Society, and the Brixton, Tulse Hill, and Herne Hill Dispensaries, all free of legacy duty

A Novel Sewage Method.—The Bingley local board of health have been placed in a peculiar position by the Home Office. The board experienced some difficulty in providing for the drainage of the town, and brought their difficulties under the notice of the authorities in London. A memorial was prepared, and in it a suggestion was made that it was desirable to hold a local inquiry in order to reconcile certain differences of the parties interested. The Home Secretary sent down Mr. Robert Morgan in September last; and he has reported to Mr. Bruce that sewers should be constructed throughout a good part of the town at a sufficient depth to prevent all sewage matter from entering the streams or watercourses, such sewers to convey all sewage matter to land suitable for its utilisation by irrigation. The Bingley local board have decided to carry out the scheme.—*Bradford Daily Times*.

Death of Mr. Toogood, F.R.C.S.—The death of Mr. Jonathan Toogood is announced at the age of eighty-seven. The deceased was the founder, and for many years surgeon, to the Bridgwater Infirmary, Mr. Toogood was the senior fellow of the Royal College of Surgeons of England. His diploma bears date May 4, 1804.

Extraordinary Number of Sudden Deaths.—During the past week Dr. Lankester, coroner for Central Middlesex, has held no fewer than forty-three inquests. Of these a no less number than twenty-seven were cases of sudden death, and of these twenty-seven five were inmates of St. Pancras Workhouse. In the course of the inquiries the coroner remarked that the first week or two of cold weather at the commencement of each winter produced more cases of sudden death than any other period of the year,

The Medical Society of the College of Physicians, Ireland, will hold its third meeting, on Wednesday, 14th December, when the following communications will be read:—1.—Dr. Cameron—"Is the flesh of diseased animals unwholesome food." 2.—Dr. H. Kennedy—"On the views of Niemeyer regarding Phthisis." 3.—Professor Moore—"On Stimulation in Fever."

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

We have read the "Chemist's and Druggist's Almanack and Diary for 1871," which seems to be full of information that is sure to be useful to those for whom it is designed. Professor Attfield gives an introductory article entitled, "Pharmaceutical Chemistry, 1870;" Mr. Tilden adds one on the "Gravimetric Tests of the Pharmacopœia;" and there is also a full account of the "Chemical Tests for Medicinal Substances," by Mr. Sydney Rich. It will be very useful to lie on the dispensing counter.

An article on "The New Rules for the Government of Irish Lunatic Asylums" is in type, but is unavoidably held over.

Dr. Tucker, Sligo, must surely be aware that the Irish Medical Association is bound to disclaim personal support of any candidate. The letter was printed from your own copy. If there are errors in it, they shall be corrected on your pointing them out to the Editor.

Dr. Atkinson, Athlone.—The degrees are not the least use as qualifying to register or hold any public appointment. They confer no right to practise, but a person holding them can evade the law and practise at the risk of prosecution just as a person with no degree whatever may do. Except that they give the holder a couple of letters to attach to his name, which he would probably be better without, these degrees are not the least use.

A Dublin Correspondent complains to us that the British Medical Association has billed him for subscription for three years—our correspondent represents that, like many other practitioners in Dublin, he joined the Association in the year when its meeting was held in that city in order that he might be entitled to attend the meetings. For that year he received the "Journal of the Association," but, at its termination, it ceased to come to him, and he has not since then been aware that he has been considered a member. He finds, however, that his name appears on the published list of last year, though he was unconscious that he enjoyed such privilege. It does seem rather a one-sided method of business to demand payment while withholding the only real value for the money.

L.S.A.—By all means take the college diploma. It is more difficult to read up later, and you will always feel the want of a double qualification.

Auctor.—The book has not been received. Your publisher should be instructed to send it, if you wish it reviewed.

AN AMERICAN VIEW OF OUR NEW POSTAL ACT.

"Our English and Irish exchanges come to us (*Boston Med. Journ.*) this week in a state nearly approaching disorganization, that we are led to investigate the cause. We find that the retaining thread which has hitherto bound together the various sheets of the foreign periodicals has been cut by an *absurd* order from the British Postal Department, a species of red-tapeism which is, to say the least, a matter of inconvenience to the readers of the Journals. In future, all stitched periodicals are excluded from the mail rates provided for newspapers, and our contemporaries are forced to incommode their patrons or else subject them to an exorbitant postage rate." Our readers will, we are sure, fully endorse this opinion, for a more absurd restriction was never imposed.

THE COST OF DIMPLES.

Can any of our readers kindly inform us what connection there exists, or is supposed to exist, between dimples and the supply of Hambro' sherry, and other wines? Last week a contemporary indulged its readers with an article upon the supply "after the Spanish model," of wines to the sick and wounded, and the public generally, with the above extraordinary heading. But what we wish particularly to draw the attention of the writer to is, a new rule in arithmetic which he has for the first time to our knowledge, introduced; he says, "six imperial quarts do fairly make up a gallon." Our boyhood "Weights and Measures Table" taught us that "four quarts make one gallon." Perhaps our contemporary the *Brit. Med. Journ.* will kindly set us right with the above queries as we are anxious to keep ourselves *au courant* with "things new and important."

BOARDS OF GUARDIANS.

It appears that the annotation upon this subject, which appeared in our issue for Nov. 30th, has raised the ire of the Worcester Board to such a pitch that a resolution was passed on Thursday on the motion of Mr. Minchall, "That the clerk be requested to write to the *Medical Observer* (a new name by the way, for the Medical Press and Circular), to ascertain whether the observations where the Editor's own remarks, or whether they were suggested by any correspondent, and, if so, who?" We would have written, and, "if so, by whom." However, as a knowledge of "Lindley Murray" is not usually considered a necessary qualification for parochial Boards, and the foregoing motion had not reached us at the time of going to press, we may state, for the edification of the Board, that the article in question was written by a member of our staff, and the opinions founded upon reports which appeared in the Worcester journals. Mr. Minchall objected to the term "mercenary" as applied to the body of which he was a member, when "their *most important* duty was to take care of the rates." We would take the liberty of reminding this gentleman in the most friendly way possible, that the care of the poor *should be* the chief aim of Guardians, and that those who wilfully neglect their duty in this respect, by tying the hands of their medical officers, or disregarding the wants of the sick and destitute, simply for the purpose of "taking care of the rates," are guilty of a most flagrant and cruel breach of trust. In the course of our former article, we remarked that the Worcester Board "had lately made a public bid for this distinction"—(*i.e.*, mercenary). We did not say it attained to that degree of notoriety, as the good sense of some of its members, rescued it from such an unenviable position, upon which non-homogeneous character, we did and do now congratulate the Board. Our remarks were written purely in the interests of the profession and the public, and we have nothing more to, add to or withdraw from, our previous comments.

VACANCIES.

Castlebar Union.—Medical Officer for the Dispensary District No. 2. Salary £110, exclusive of fees. (See Advt).

Dublin Fever Hospital (Cork Street).—Temporary Physician. (See Advt).

Liverpool Dispensaries.—Assistant Resident House-Surgeon. Salary £103.

Preston Royal Infirmary.—Senior House-Surgeon at £80 per annum, and a Junior House-Surgeon at £60 each, with board and residence.

West Kent Hospital Maidstone.—Resident House-Surgeon. Salary, first year, £100, second year, £125.

St. Pancras, Middlesex.—Medical Officers for each of Districts 1 to 8. The Salaries for Districts 1, 2, 6 and 7, are £100 each per annum. District 3, £120. Districts 4 and 5, £110 each. District 8, £130 per annum. Drugs and medicines are provided by the Guardians. Election the 15th.

St. Marylebone, Middlesex.—Public Vaccinator. Average fees per annum £165.

County Down Dispensary and Fever Hospital.—Registrar and Surgeon's Assistant. Salary 60 guineas, with board and residence. (See Advt.)

APPOINTMENTS.

Barbour, J. B., M.D., L.R.C.S.Ed., Resident Medical Officer at the Stockwell Fever Hospital.

Bloxam, Professor, has been elected Professor of Chemistry at King's College, London, vice Dr. W. A. Miller, deceased.

Debus, Dr., F.R.S., Examiner in Chemistry at the University of Lond. vice Dr. Matthiessen, F.R.S., deceased.

Drake, Mr. A. J., House-Surgeon to St. Thomas's Hospital.

Franklin, Mr. G. C., House-Surgeon to St. Thomas's Hospital.

Goss, T. B., M.R.C.S., Medical Officer to H.M.'s Post-office, Bath.

Gordon, Mr. J., House-Surgeon to Gray's Hospital, Elgin.

Green, Mr. J., House-Surgeon to the Ophthalmic Wards of the Royal Infirmary, Edinburgh.

Hardino, T. H. G., L.D.S.R.C S.E, Dental Surgeon to the Dental Hospital of London.

Hughes, R., F.R.C.S., Consulting-Surgeon to the Staffordshire General Infirmary, Stafford, on resigning as Surgeon.

Jolly, R., F.R.C.S., Surgeon to the General Hospital, Birmingham.

Lomax, H. T. M.R.C.S., Surgeon to the General Infirmary Stafford.

Macdonald, John E L., Haswell Colliery, Poor-law Medical Officer and Public Vaccinator, Thornley District of the Easington Union.

M'Cann, C., M.R.C.S., Resident Medical Officer to the Stockwell Small-pox Hospital.

O'Reilly, R., L.K Q.C.P.I., Medical Officer for the Ballyduff Dispensary District of the Lismore Union, Co., Waterford.

Osborn, Mr. Samuel, Resident Accoucheur to St. Thomas's Hospital.

Owen, O. E., L.R.C.P.Ed., Medical Officer for the Llanidan District of the Carnarvon Union.

Pinder, G. H., M.R.C.S., Senior House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester.

Rickards, E., B.A., F.R.C S., Resident Registrar and Pathologist at the General Hospital, Birmingham.

Ross, J., M.D., Medical Officer to the Elgin District Lunatic Asylum.

Steven, Mr., Dental House-Surgeon to the Dental Hospital of London.

Turner, H. G., M.R.C.S., House-Surgeon to the Brighton Dispensary.

Wade, W. S., L.R C.P.Ed., Medical Officer for the Sandal Magna, Walton, and Chevet Districts of the Wakefield Union.

Way, J. P, M.R C.S., Medical Officer for the Laudport District of the Portsea Island Union.

The Medical Press & Circular.

HYDRATE OF CHLORAL.—ITS POSITION IN MEDICINE.

By Robert Uniacke Ronayne, L.R.C.S.I., &c.,

Youghal Infirmary.

It is a vice to be deplored, yet not exclusive in our age, that almost every new agent which refined chemical research calls into existence, or extended botanical investigation reveals to our knowledge, is eagerly hailed as likely to prove an almost universal panacea, and supply in medicine the place the philosopher's stone was hoped to fill in alchemy. For a time it runs a brilliant and seemingly successful career; then follows a short period of flickering distrust and neglect, and then the new meteor which has dazzled the medical sky out of its propriety, and casts some of the steady old fixed stars into shadow, dies obscurely out, and we are not a whit better lighted than before its advent. This moth and candle mode of seeking an exit from our darkness, by dashing frantically after the first bright novelty that crosses our path, does an incalculable amount of mischief to our young practitioners, many of whom after meeting frequent and vexatious disappointments in the trial of new remedies, run the risk of becoming slovenly routinists by discarding real improvements, and holding too tenaciously to what they have found good in the old ways. On the other hand, very many useful drugs which, if introduced to notice with modest impartiality, might have retained a third or fourth rate permanent position, have sunk into comparative disuse by the reaction produced on their falling short of realizing the bombastic expectations which heralded their appearance. I am led to these considerations by noticing a tendency lately in certain professional circles to question the right of the hydrate of chloral to a standard position, since it has failed to attain results, the accomplishment of which would simply make it an "elixir of life," and because many disappointments in the trial of new medicines caused me at first to view its introduction with little interest, therefore, as I know that some of my brethren who are still similarily apathetic, I think it right to make record of the change which careful observations of the drug have wrought in my views; and, as my experience of its powers are derived from having prescribed it over five hundred times, I am able to speak with confidence of many of its benefits, peculiarities, and shortcomings.

Chloral is an artificial organic chemical compound composed of C_2 HCL_3 O, it combines with water and is soluble in the same element, both hot and cold, but insoluble in dilute sulphuric acid. It was discovered by Liebig in 1832, but was not utilized in medicine until very lately, when Liebreich, of Berlin, pronounced it to possess anæsthetic and hypnotic properties in no ordinary degree. M. Bouchut's investigations soon followed, and resulted in his declaring it a sedative to both motor and sensitive nerves; and since then the observations of many British and foreign physiologists have confirmed these reports. The manner in which chloral achieves its medicinal action is peculiar. According to Liebreich, Personne, Bussy, and Richardson, its narcotic effects are due to chloroform, which is slowly evolved in the system—the chloral being acted on by the alkalies of the blood and chloroform with formate of these alkalies being the products. This hypothesis has been verified by numerous experiments on animals. In therapeutic doses chloral is spoken of as possessing two marked properties, namely:—anæsthesia and narcosis; but I hope to be able to show that it is also capable of instituting other and important actions in the system. As an anæsthetic its power is very restricted, and from the prolonged nature of its sleep, together with the absence of complete insensibility to inflicted pain and the presence of the power easily to awaken the patient, unless where toxic doses are had recourse to, it seems never likely to be much employed; yet Bouchut speaks of drawing teeth and applying Vienna paste painlessly under its influence. As a hypnotic, on the contrary, there seems no limit to the extent or variety of its uses. In this capacity, it possesses great energy, power, and safety of action—rivalling opium in its pain-relieving and

rest-giving qualities, whilst it shows marked advantages over that drug in celerity of result, simplicity of physiological effect, and freedom from after ill sequences. The rest it affords, which sets in a few minutes after its administration, is not a dull heavy torpor with congested brain and laboured breathing, such as that effected by opium, but a light, calm, easy slumber, free from cerebral or pulmonary oppression, from which the patient is easily waked, and which leaves no after sting on waking, to detract from the comfort it confers.

Thus, then, the characteristic peculiarities of the hypnotic action of chloral seems to be rapidity of access, and length of duration, absence of congestive influence, non-arrest of natural secretion, and non-inducement of after-unpleasant effects; and it is the possession of all these which gives it in my judgment the great advantage over opium and other allied medicines. The rapidity with which the chloral sleep sets in is very remarkable; ten minutes is about the limit of the stage of incubation, before the recipient of a moderate dose drops into slumber; but it is generally much shorter, and in some cases the patient is off before the nurse has well left the bedside; in fact, it is the speediest of all narcotics, and this quickness of affording relief from pain, renders it a most grateful and popular remedy. A special feature in the chloral sleep is the ability to cast off its influence for the time under the pressure of internal or external circumstances. A patient under its control wakes to the call of nature, or the irritation of severe cough, or he can be easily aroused by his attendant to receive such nutriment or medicine as his state may require, and after the disturbing excitement is removed he relapses into a calm repose again. Although in the sleep of chloral, the pupil is contracted, as in natural sleep, it instantly dilates on waking, and the concentration of intelligence on being roused returns as quickly as after ordinary slumber—leaving no drowsy, besotting effect like its half-sister, opium—and the sleep is more prolonged and quieter than that of the last named anodyne. Some assert, however, that it is disturbed by frightful dreams; this has never come under my notice, and, if it be so in some instances, it is hard to charge the medicine with the visions which a mind over wrought by illness and anxiety is capable of conjuring up. Further, should the dose of chloral prove inert as an hypnotic, no mischief is done, and no terrible unrest effected such as that which awaits the partaker of a stimulating dose of opium. It has been asserted by some writers that there is a transitory stage of excitement before the complete action of chloral takes place, and that unless the patient sleeps there is no relief from pain manifest. Careful observations have satisfied me that the first is only the case where the drug is given in doses too small to procure immediate slumber, or where surrounding circumstances, such as excess of light, or noise, tend to oppose its invasion; then the patient may find it getting into his head, but even this slight action requires some constitutional peculiarity to aid it, as I have not seen it present in more than five per cent. of my cases. And, with regard to the second, I have verified the contrary in a very large number of instances where severe neuralgic or inflammatory pain has been almost instantly removed by fifteen or twenty grains of chloral, and kept in check—in some cases driven completely off by similar repeated doses, without sleep resulting as an immediate effect. The total absence of any tendency to congestion of the brain, or lungs, during the sleep of chloral, is perhaps its most important attribute, as this property enables us to use it in a number of inflammatory and organic affections of the brain, spinal cord, lungs, and heart, where opium is especially contraindicated, although its soothing influence is often sorely needed. On this point, Sir James Simpson says—"I am not aware of any special contraindications to the employment of chloral when used for somniferous purposes, even in head and chest affections, where I should have been chary of having recourse to opium as an hypnotic, I have employed chloral with perfect success." In this respect, chloral supplies a want which the scientific treatment of disease has long deplored, and in it we find a safe and certain friend to aid us, where before we had dubious or treacherous ones; and in numerous cases where a dose of opium means little less than death or recovery, chloral is certain safety. In no state is this more clearly displayed than in the sleeplessness of typhus; rest is the sufferer's salvation, yet we are comparatively powerless to induce it. Opium is much too risky an agent to be employed, except by those who are very heroic practitioners indeed. The douche, hyosciamus, ether, leeching, and bromide of potassium often fail, and we are driven to see our patient die, or to the unwilling use of opium; here chloral is a safe and comparatively sure remedy. It has been successful in a few such cases in which I have employed it; and Dr. James B. Russell says, that it was successful in almost every form of cerebral excitement incidental to febrile disease with remarkable uniformity and rapidity. It is well to remark, however, that the extreme alkalinity of the blood in fever render the patients easily acted on by even small doses of chloral. In combating functional or organic disturbances of the brain and nervous centres, chloral appears to develop its most valuable resources; its hypnotic and general soothing properties, together with its freedom from congestive tendencies, confirm to make it peculiarly adapted to this purpose. It has been resorted to in acute mania, chorea, spasm of the portio dura, epilepsy, delirium tremens, puerperal mania, melancholia, sleeplessness, convulsions, and insanity, and over all these it asserts a highly beneficial agency; its calmative effect on the excited brain being often remarkable and readily produced. On this point, Dr. A. M. Adams observes—"That chloral will almost instantly induce sleep where the brain is functionally or organically disturbed; but acts with great uncertainty on a sound brain where pain is the exciting cause of sleeplessness." With the latter part of this remark, however, I cannot completely agree, as I have found it, with a very few exceptions, exercise a despotic power in expelling pain, whether sleep be produced or not, and in neuralgic affections, in which Dr. Adams states, he found it "rather uncertain." I have, happily, experienced the opposite result. It is not necessary to detail the effects recorded of it in all the above affections, and of them I have, as yet, only treated chorea, epilepsy, and melancholia with it, but in these I have found it undeniably useful. The medicinal introduction of chloral seems to open up an entirely new era in the treatment of *delirium tremens*, and now opium is no longer likely to goad the watchful and exhausted patient to further frenzy, or run the case between the Scylla and Charybdis of sleep and effusion on the brain, but with the bromides of ammonium and potassium and chloral we may fearlessly face the monster, keeping the old drug in reserve as a forlorn hope should they fail.

(To be continued.)

DR. CHARLES MAURIAC ON BLENNORRHAGIA IN WOMEN.

By Charles R. Drysdale, M.D., M.R.C.P.L., F.R.C.S.E.,

Physician to North London Hospital for Diseases of the Chest, Hampstead, &c.

(*Continued from page* 477.)

With regard to *virulent vaginitis*, there are cases when the vaginitis at once extends to the whole surface of the vaginal canal; others which are local from the outset, or when the first fire of inflammation has died out. Most generally the process goes on from before backwards, from the vulva towards the deep parts of the canal; but it may take place in an inverse order, that is, from the cervical

portion of the vagina towards the vulva. This last fact is rare. When vaginitis is anterior or vulvar, it provokes, if violent, an inflammation, or rather a sympathetic engorgement of the inguinal glands. These glands may even suppurate, but the pus they furnish is not inoculable like that which is developed in the case of soft chancres, and the blennorrhagic bubo nerves spontaneously become chancrous. The vaginitis, or the deep parts, of the canal does not affect the inguinal glands. We find the explanation of this fact in the distribution of the lymphatic vessels: those of the posterior half of the vagina go to the glands of the pubis; those of the anterior half to the internal glands of the inguinal region. When vaginitis passes into the chronic stage, it is rare that it confines itself in the vaginal *cul-de-sac*. It is then habitually complicated with blennorrhagic inflammation of the neck of the uterus and cervical cavity. These two affections, acting one on the other by contact and reciprocal contagion, are perpetuated indefinitely. They may coexist in the sub-acute stage, with a healthy condition of all the other parts of the genital mucous membrane. Frequently, they are not suspected, but because a woman who believed herself healthy gives a clap, and they are only discovered by means of a minute exploration of the *cul-de-sac*. The speculum in such a case, after undoing the folds of the anterior and middle part of the vagina, falls into a kind of cloaca filled with purulent viscous mucosity, in the midst of which the uterus is bathed. These mucosities are constituted by a more or less intimate combination of the pus which belongs to the blennorrhagia and of the viscous, stringy, limpy liquid, which is the usual product of uterine cervical catarrh. When the neck is wiped clean, we perceive on its surface, and on the *cul-de-sac*, the following lesions which may make us suspect the existence of a blennorrhagic affection, but which, however, have nothing characteristic. In the *cul-de-sac* the mucous membrane is thickened, and of a dusky red colour; in places the epithelium is absent, and there are very superficial erosions. These bleed easily, and secrete muco-pus. These alterations are almost always much more marked in the posterior *cul-de-sac* than in the anterior one; and for this simple reason it is into the posterior *cul-de-sac* that these fall continually, the mass of vitreous mucus, striated with yellowish purulent streaks arising in the cavity of the neck, which is specifically inflamed. The mucous membrane covering the neck is congested, erythematous, of a cherry-red, violet, or wine-colour, according to the chronicity of the disease. Its papillæ are prominent, turgescent, bristling, and give it a velvety appearance. The whole organ is congested and elastic to the touch. There exists almost always on the mucous membrane ulcerations occupying the whole of the circle of the orifice or posterior lip of the os tincæ. Sometimes these are disseminated upon the whole external surface of the neck, and become united to those which exist in the vaginal *cul-de-sac*. The ulcerations which leave bare the superficial layer of the mucous derma are caused solely by loss of the epithelium. They are multiple, irregular, festooned, and sometimes not distinguishable from the surrounding parts, except by the deeper colour they possess, and especially by a dull want of polish, easily remarked when the viscous mucus covering them is rubbed off. In some cases their surface is covered by a thin, pseudo-membranous layer of one kind of false membrane of the same kind as all febrinous exudations. As these ulcerations get old, they become salient, unequal, and mammilated, because the little wrinkle of the surface of the mucous membrane despoiled of their mucous membrane are converted into true fleshy granulations.

Amidst these lesions we sometimes see, here and there, rounded prominences, about the size of a pea, of a more or less dusky hue, formed by the follicles of the cervical mucuous, which secrete and retain some blennorrhagic muco-pus. This is the blennorrhagic folliculites of the neck. As we have seen, the preceding alterations do not much differ from those we find in certain catarrhs of the neck, which have no blennorrhagic origin. Thus, Dr. Mauriac maintaining that the diagnosis of specificity without the effects of contagion is impossible. But *à propos* to these kind of cervico-vaginitis, the question always occurs: Is it impossible that a woman exempt from all blennorrhagic contamination, and nevertheless presenting, as may happen, the lesions just described, should communicate a discharge by connection? If you answer that she may, but that this discharge has nothing to do with true blennorrhagia, and that it cannot be transmitted, &c., you are a well convinced specificist. But your conviction will not prevent another person from believing that you would have been wiser if you remained in a methodic doubt, until very positive and irrefutable experiences had been made.

As to granular vaginitis, if it is sometimes the effect of blennorrhagic contagion, we must also recognise that it is often developed under the influences of other causes, among which we must mention, first of all, pregnancy, then catarrhal affections of the uterus and cervix, which keep up a continual condition of hyperæmia in the vaginal mucous membrane. Some have remarked it in women with abundant leucorrhœa, and who yet have not communicated any contagion. These granulations are often met with on the neck in specific cervico-vaginitis. They have the form of a hemisphere and volume of a grain of millet; their colour is rather dusky red. They give a raspberry look to the parts they occupy, when they are confluent. Blennorrhagic inflammation, when concentrated in the vaginal *cul-de-sac* and in the neck, is a cause of cervico-uterine catarrh. But, in its turn, secondary cervico-uterine catarrh, by provoking a more considerable afflux of blood towards the diseased parts, and irritating by contact of its products the ulcerated surfaces, prevents the specific inflammation from subsiding.

In vaginitis, as in urethritis and vulvitis, we must have recourse to antiphlogistic treatment by baths, emollient injections, sothing drinks, repose, moderate diet, and slight purgation, when the inflammatory phenomena are very violent. When the acute period, which is generally but of short duration, has passed away, we ought to have recourse to truly heroic remedies, among which Guerin places among the first of all a plug of lint filled with powdered alum. As to injections, we may use a table spoonful of alum in a quart of water, or a solution of a drachm of sulphate of zinc to the pint of water. As to nitrate of silver, we should apply dressings on the whole of the walls of the vagina, without omitting any point. The solution ordinarily used is fifteen grains to the ounce.

Blennorrhagia relapses with greater facility in women than in men perhaps, because there remains either in the folds of the vagina, or in the muciparous follicles, or more frequently again in the cavity of the neck, points of specific inflammation, which have escaped the action of the agents employed. These localised inflammations remain sometimes latent for a long time and as if unoffensive; then, under the influence of unaccustomed excitation, they awaken, extend, and bring on a true blennorrhagia, which is taken always for an ordinary catarrh, because the specific catarrh is supposed to be cured a long time. The blennorrhagia has the same complications of rheumatism and ophthalmia in women as it has in men. The vaginal inflammation is propagated to the neck and body of the womb as it attacks the pustule. It attains by means of continuity the ovaries, and attacks them by a kind of metastasis, precisely as it does the testis. Lastly, the Fallopian tube, the analogies of the vas deferens, may become indurated, voluminous, and rigid and painful, absolutely like the chord in male blennorrhagia. If the bladder and kidneys are more often spared in women than in men, in revenge, the pelvic peritoneum is more frequently affected. This admirable summary of modern researches on blennorrhagia in women, by Dr. Mauriac, seems to me to be of much practical importance to all practitioners, and to be, perhaps, the most complete statement of the nature of the disease as it occurs in women, yet written.

CLINICAL MEMORANDA.

SUBCUTANEOUS INJECTION OF MORPHIA.

Reported by JOHN W. MARTIN, M.D., Assistant-Surgeon Mayfield Factory Dispensary, &c.

(*Concluded.*)

CASE 7.—*Incipient Symptoms of Pneumonia.* — Mrs. Deasey, æt. twenty-five; notes taken, August 28th, 1870. Had always been a strong, healthy subject. On the Wednesday preceding my visit, August 24th, 1870, she had had a severe headache, pains in the bones, and general feverishness, the result of a chill, which she had got the previous evening whilst out walking.

Symptoms at time of visit.—Four o'clock, Sunday, 28th August, 1870.—Pain in the region of the apex of the heart, the action of the latter being greatly excited. First. Sound exaggerated and roughened; dyspnœa, the respiration being greatly hurried; headache; pains in the legs, and weariness of the body; face flushed; respiration, 36; pulse, 120; temperature, 104 4-fifths. The skin dry, hot, and *very pungent* to the touch; tongue clean and well protruded; no abdominal pain, or uneasiness; bowels acting freely. A deep inspiration induces a smart attack of pain on the left side; slight dulness and tubular breathing, apparent on the left side, in the middle lobe; no rusty sputa or cough.

Treatment.—Turpentine stupes, followed by poultices applied to the left side. A mixture, containing aq. acetatis ammoniæ and nitrate of potash, given every fourth hour. On visiting her at nine o'clock, she felt lighter, skin moist and perspiring; pulse, 120; respiration, 28; temperature, 102 2-fifths. Pain about the apex of the breast easier. She felt very restless and disinclined to sleep, so I injected one-quarter grain of solution of morphia into the arm. No change took place in the temperature after the operation, as shown by the thermometer.

Monday, August 29th, 1870.—About twenty minutes after my leaving her, on the preceding evening, she fell asleep and had a pleasant night's rest. To day, skin cool and moist; face losing the flushed appearance it had; all pain about the heart gone; heart's action quiet, both sounds distinct, no murmur; appetite returning; temperature, 98 2-tenths; respiration, 20, tranquil; pulse, 72; the bowels constipated, and the tongue somewhat dirty; ordered a dose of castor oil.

Tuesday, August 30th, 1870.—Bowels well acted upon by the oil. Tranquil; slept well; tongue clean, and well protruded; appetite improved; pulse, 80; respiration, 20; temperature, 98 2-tenths. Ordered quinine mixture; convalescent.

The foregoing cases illustrate, I think, in a marked degree, the usefulness of this method of administering remedies, especially those by which we seek to relieve pain, where immediate action is the great desideratum. In addition to the above, I have used it largely in cases of colic, of rheumatism where ordinary anodynes failed to procure rest, of sciatica, and in one case of well marked coxalgia, in all with good effect. In the case of coxalgia, however, I only used it as a palliative; as such it proved most beneficial, giving the patient lengthened intervals of rest from pain, after all other remedies had failed to procure such. A word as to the method I observe in administering it, I use a solution of gr. ij. of muriate of morphia in ℥ 40 of warm water, *using no acid* to assist in its solution. Having charged the syringe with six minims of the solution, I generally select as the place for injection the insertion of the deltoid, pinching up a fold of the skin in the long axis of the limb; I introduce the needle from above downwards rapidly and steadily to the full length of the canula, then, withdrawing slightly, I gradually throw in the required quantity. After taking the instrument out, I secure the opening by a small bit of adhesive plaster. *Up to the present I have never seen any bad result follow the puncture;* on the contrary, in every case in which I have used the hypodermic syringe the patients have invariably experienced *immediate and decided benefit* from the morphia so administered. *In no case have I seen sloughing or inflammation follow the operation.*

NOTES ON SPERMATORRHŒA.

By ABBOTTS SMITH, M.D., M.R.C.P. Lond., M.R.C.S.,

Physician to the Finsbury Dispensary; late Physician to the North London Consumption Hospital; Physician to the Metropolitan Free Hospital, and to the City Dispensary, &c.

FOR many years past, I have had extensive opportunities of observing, at the various institutions with which I have been connected, as well as in private practice, the frequency of cases of spermatorrhœa, and I have been especially struck by two facts, namely,—1. The remarkably helpless and dejected state of patients suffering from this affection, and 2. The relative facility of cure, as compared with numerous other disorders of the genito-urinary organs, if the patients remained under treatment for a reasonable period, and if they, at the same time, relinquished the bad habit which, in a certain proportion of the cases had brought on, or tended to perpetuate the ailment.

A third feature presented itself with almost uniform regularity, and this was that in most of the cases (at any rate, in something like two-thirds of the whole number under observation), the patients had, before applying for hospital advice, foolishly placed themselves in the hands of ignorant, unscrupulous quacks, who, acting on the principle of the old highwayman's maxim "your money or your life," had rapaciously extorted as much as they could of the former, while their victims ran no small risk of also losing the latter. To a certain extent, some of the sufferers could scarcely be blamed for their apparent want of discrimination in going to such men, as they had, in the first instance resorted to medical practitioners, who had told them, either that their disorder was imaginary, or, rushing into the opposite extreme, that it was incurable, or only to be removed by the progress of time.

It is not a little singular that the medical profession should have assumed such an apathetic or indifferent position, as regards this disorder. There can be no doubt of the existence of spermatorrhœa in a large number of patients, and, in fact, it would be found to be much more common than it even appears to be, if it were more generally recognised as a distinct affection. Many of the cases which now fall into the hands of empirical pretenders, would then come within the range of observation of qualified practitioners. And this must, sooner or later, be the case when the false delicacy which is at present allowed to surround the subject of spermatorrhœa is removed. It is the conscientious duty of medical men, standing as they do in the position of guardians of the public health, to grapple resolutely with this, as with every other phase of disease, instead of leaving unfortunate sufferers exposed to any charlatans who may happen to seize upon it as a fertile field for deception and extortion. I write thus earnestly, because many instances have been published in the medical journals of patients—often of superior education, intelligence, and social position—who have suffered severely at the hands of quacks, partly through their complaint having been treated too lightly by medical practitioners, to whom they had previously applied for advice, partly through the *mauvaise honte* which induced them, misled by the specious promises held out, to fall into the traps set by quacks. "*Omne ignotum pro magnifico*" is an old and true axiom concerning the credulity of sick people, who, like drowning men, readily snatch at any proffered assistance without waiting to form an opinion as to whether it is worthless or sound. With regard to the almost culpable distaste for dealing fully with the subject, I am of the same opinion with that which

was recently expressed to me by the editor of a medical journal, that there can be no more real reason for ignoring the functional disorders of the male, than those of the female sex, upon which so much has been written and said of late years.

The general symptoms of spermatorrhœa need not be dwelt upon, and I shall purposely pass over the minutely detailed and grossly exaggerated symptoms, which the quacks carefully and persistently parade before their victims' imaginations, such as, "involuntary blushings," "loss of vigour," "gradual decay of nature," and the like.

Suffice it to say, that the general symptoms are similar to those which are present in all cases of disease where the patient is subjected to the effects of continuous exhaustion of the system. He becomes languid, weak, and unfit for any sustained physical or mental exertion, disposed rather to brood in solitude over his misfortunes, than to join in social conversation and amusements, thin, pale, and anæmic in appearance.

In the majority of cases, especially of those which are connected with masturbation, the patient is unwilling to speak of his ailment, and is particularly reticent concerning its causes and nature. To this peculiarity may be attributed, in great measure, the uncertainty and difficulty of treatment. A physician may go on for a long time, treating a case of this kind by general measures, but unless he should eventually suspect its real character, and satisfy himself, by closer questioning, of the accuracy of his suspicions, no improvement will be manifest in the condition of the patient. In fact, the patient will be further off from a cure than ever; the physician, unconscious of the "*fons et origo mali*," will get baffled and disheartened at the continuous want of success, while the patient, becoming more reticent, and it may be more addicted to the bad habit, will fall into an almost hopelessly chronic state of illness and despair. How much better would it be for the patient's health and happiness, if he could face the matter boldly, and at once disclose the nature of his case to his medical adviser. "Half-confidences are bad," remarked one of our most distinguished judges, Lord St. Leonards, with reference to legal consultations; what then, must half-confidences be in a medical consultation where the real nature and origin of the case are known only to the patient himself?

If the patient gives a fair history of his ailment, the physician will usually be enabled to mark out a definite course of successful treatment.

In all instances, however, where any doubt exists, or where the physician suspects the patient of reserve in stating the facts of the case, the microscope will be found a most valuable assistance towards the formation of a proper diagnosis. A mere ocular inspection of the urine, or submitting it to the ordinary chemical tests, will not furnish so certain a means of diagnosis in spermatorrhœa as in most other disorders of the genito-urinary organs. For instance, when only a small proportion of spermatic fluid is present in the urine, it may, upon superficial examination, be mistaken for mucus, and thus escape detection. In some cases, chemistry may be sufficient to demonstrate the nature of the disorder. "If," wrote my learned predecessor at the Finsbury Dispensary, Dr. Golding Bird, "we have a specimen of urine passed by a man, which is cloudy and opalescent, reddens litmus paper, and does not become clear on the application of heat or of nitric acid, the presence of spermatic fluid may be at least suspected. Should a larger quantity of this secretion be present, it subsides to the bottom of the vessel, and may be recognised by its physical character." But, it is only in extreme cases, that spermatozoa can be thus detected, and it is better in any circumstances, to have recourse to microscopical investigation.

For this purpose the urine should be permitted to stand for some hours in a conical-shaped glass, so that the spermatozoa may be separated from the fluid, and settle with the mucus at the bottom of the glass. The upper portion of the fluid should be then carefully poured off, and two or three drops of the sediment be placed upon a slip of glass, covered with another slip of glass, and afterwards put under the microscope. The little thready spermatozoa and the spermatic granules can then be recognised. When they are recent, the spermatozoa have a spherical form, with a well-defined tapering tail, resembling very minute tadpoles, and are capable of spontaneous motion. If the urine is very acid or alkaline, they soon lose their movements, and undergo a change of form, owing to the rolling up of the tail part towards the body of the animalcule.

Urine which contains spermatozoa soon becomes alkaline. Octahedral crystals of oxalate of lime are often found in company with spermatozoa; in fact, according to some writers, the appearance of these crystals in the urine of the male subject, affords strong presumptive evidence of the co-existence of spermatozoa.

The causes of the admixture of spermatozoa with the urine are various. They may remain in the urine after emission, and be subsequently discharged with the urine. They may also be present, owing to an irritable condition of the vesiculæ seminales, in connection with sexual excesses or onanism, with paraplegia, and some other disorders of the nervous system, diabetes, inflammation of the bladder, stricture, constipation, and hæmorrhoids.

An affection to which the name of spermatorrhœa is sometimes, but improperly, applied, is a discharge which takes place from the urethra, when the patient is at the closet, particularly if the bowels are much confined. This discharge, which gives rise to great alarm in the mind of the patient, may not be seminal, or be only slightly so, and consists principally, or entirely, of a mucous secretion from the vesiculæ seminales. It is the result, usually, of over-excitation of these organs, or is produced by urethritis and epididymitis, so that it is then a kind of gleet. A similar discharge may take place under the effects of mental excitement arising from impure thoughts, or reading lascivious books.

Another phase of the affection, which is often very difficult to treat, and produces the most disastrous consequences upon the patient's health and spirits, has an existence chiefly in the mind of the sufferer, who fancies himself to be rendered impotent, and thereby disqualified for marriage: sometimes a patient of this class will brood over his sufferings until he becomes a monomaniac.

The treatment of spermatorrhœa will consist—1. In the administration of such general remedies as will improve the patient's general health; 2. In preventing the continuance of the involuntary discharges; and 3. In promoting a higher moral tone.

As most of the patients who suffer from this exhausting disorder are in a low, anæmic condition, tonics are especially indicated. Foremost amongst these are the preparations of iron and zinc, and quinine. The tincture of the perchloride of iron may be given in doses of fifteen to thirty minims; in cases where this preparation is badly borne by the stomach, and produces indigestion and nausea, the compound iron mixture or pill, the *Ferrum reductum* of the "British Pharmacopœia," or the ammonio-citrate of iron may be substituted for the perchloride.

Zinc may be administered in the form of either the sulphate in doses of one to three grains, or the valerianate in half-grain to two-grain doses. The best mode of giving these salts, is by making them into a pill, with extract of anthemis or hyoscyamus.

When quinine is indicated, the tincture is the preparation which I consider preferable. As is also the rule during the administration of ferruginous remedies, aperients must be given occasionally to prevent the headache, &c., which are apt to occur if the patient's bowels should be confined during its employment.

If the nervous depression is strongly marked, and especially in patients of cachectic constitution, phosphorus, or its compounds, may be resorted to. Pills containing phosphorus may be made according to the following formula (*vide* "Druitt's Surgical Vade Mecum"):—Take of crumbs of bread, a drachm; of distilled water, as much as may be

sufficient to render the mass of a proper consistence, then add one grain of phosphorus. Mix the mass well together, and divide into twenty pills, of which one may be given three or four times daily. A more convenient method of administering phosphorus is either in the form of an ethereal tincture, composed of four parts of phosphorus, dissolved in two hundred parts of ether; or of phosphuretted oil, consisting of ten grains of phosphorus, dissolved in an ounce of almond oil. The dose of these preparations is from five to ten drops, given in emulsion. With regard to the chemical compounds of phosphorus, I have found the hypophosphites of soda and lime very serviceable, in doses of ten to fifteen grains, given in some bitter infusion.

In other cases, again, particularly where the emaciation has been excessive, considerable benefit may be obtained by the administration of cod-liver oil, with equal parts of lime-water. I may here remark that I have frequently seen amongst the male patients at the Consumption Hostal, cases of supposed phthisis occurring in youths between fifteen and twenty-five years of age. Not having been able to discover any positive signs of consumption, I have been induced to make further inquiry, and have learned that the emaciation and debility were due to the spermatorrhœa, which in these cases generally arose from self-abuse. It is in this class of cases that I have observed the most decided benefit from the administration of cod-liver oil, with lime-water, and of the hypophosphites.

When the appetite is bad, and the tongue furred, and the patient suffers from occasional profuse perspiration, the dilute mineral acids are indicated, or the aromatic spirits of ammonia, with the compound infusion of gentian. It is in similar cases that the affection is most commonly associated with oxaluria, so that I give the preference over other mineral acids to dilute nitro-hydrochloric acid, owing to its valuable power in diminishing the quantity of oxalate of lime in the urine.

In spermatorrhœa the bowels are usually confined, and their regular action should therefore be insured by the administration of some mild aperient, the disorder being always aggravated by any tendency to constipation. Podophyllin, in small repeated doses, fulfils this indication better than most remedies of this class. Aloes and colocynth should be avoided, in consequence of their irritating effects upon the lower portion of the intestines.

Sedatives are necessary, in order to allay the excessive nervousness of the patient, and the local spasmodic irritability. Amongst these I place the most reliance in the bromide of potassium, given in full doses. When the unhappy sufferer is in a low, desponding state of mind, when he is a prey to irritable brooding over his troubles, or when he is attacked by vertigo or epileptiform convulsions, no remedy appears so readily to calm the nervous system, and to effect such speedy improvement in the patient's health and spirits, as the bromide of potassium.

The preparations of opium have been favourably mentioned by some writers on this subject, but they are apt to disappoint the expectations of the physician through their tendency to produce disturbed dreams during sleep, as well as by the constipation to which they often give rise. The *liquor opii sedativus*, and the salts of morphia, are less liable to these drawbacks than other opiate preparations. The same objections do not hold with respect to conium and cannabis Indica. The compound conium pill, given every night, in five or ten grain doses, either alone or combined with camphor, is a very useful remedy. The hydrate of chloral has also been productive of very good results in cases for which I have prescribed it.

If there should be any degree of scalding when the patient passes water, or if there should be frequent micturition, with an irritable condition of the bladder, and scanty, high-coloured urine, uva ursi, buchu, or pareira may be given, in combination with carbonate of soda or potash, and tincture of hyoscyamus, bromide of potassium being substituted for them as soon as the urine becomes more copious, and less highly coloured.

Instrumental interference is always attended with risk, and often with positive injury to the patient, notwithstanding the assurance to the contrary which is made by those who advocate the treatment of spermatorrhœa by the application of caustic to the urethra, or by powerfully astringent injections.

The employment of elastic, or non-elastic rings, by means of which pressure is exercised upon the course of the urethra, with the idea of mechanically restraining the discharge of spermatic fluid, is still more to be deprecated. Such appliances cannot cure, nor can they even check the progress of the disorder, while the constant irritation which they keep up is, of course, very injurious to the patient.

It not seldom happens, where the affection has been brought on by masturbation, that the patient unfortunately remains so much enslaved by this body-and-soul-destroying habit, that, despite of all curative measures, the progress towards health is seriously retarded. In such cases the application of a small quantity of blistering fluid to the penis, so as to form a ring around it, is an excellent adjunct to other treatment, by its rendering that organ tender to the touch, and consequently seconding the efforts made by the patient to discontinue the injurious practice.

The diet should consist of plain, wholesome food, easy of digestion. Spiced or salted dishes should be avoided, as should also the excessive use of alcoholic stimulants. The dinner-hour should be early, not later than three or four p.m. A glass or two of good beer may be taken with this meal, and the patient may also have a couple of glasses of port wine after dinner. Late suppers are objectionable. At breakfast and tea-time, the best beverages are cocoa and milk, neither tea nor coffee being advisable. The patient should retire at an early hour to bed, and rise proportionately early in the morning.

A moderate amount of out-door exercise should be taken daily. Walking is the best form of exercise; riding on horseback is inadmissible in most cases, owing to the tendency to increase the local irritability.

Bathing can scarcely be spoken too well of. The patient should, if not previously accustomed to the regular habit of daily bathing, commence by sponging the whole body every morning in tepid water, gradually decreasing the proportion of warm water, until at last cold water is alone used for this purpose. Cold bathing is beneficial by its improving the action of the skin, invigorating the body generally, and astringing the relaxed local structures.

Lastly, the patient's mind should be agreeably occupied, in order to divert his thoughts as much as possible from his ailments. In many instances, if a more healthy tone of mind can be established, a more healthy state of body soon follows, and a speedy cure may not unfrequently be obtained.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XVII.

PRECIPITATION OF SEWAGE WITH THE SALTS OF ALUMINA AND IRON.

CHLORIDE of iron and lime were formerly employed as precipitating agents for the sewage of Northampton, and when the process was conducted in a proper manner the results were highly satisfactory. At the time of our first visit to the place, in 1862, the sewage was only about 400,000 gallons a day, the town being but partially drained, and it flowed by gravitation to the works, which are upon the banks of the River Nene, about half-a-mile from the town. As it entered the works it received a dose

of lime and chloride of iron from two small tanks, which were charged in the following manner:—Each tank contained its own material in a solid form, and it was supplied with water from a small tap that was constantly running. The solution and suspension of the materials in the water were effected by means of revolving stirrers moved by a boy, and the overflowing water carried the solutions into a common pipe, which discharged them into the sewage. The solutions, therefore, became mixed, and were decomposed before they reached the sewage. There was no contrivance for agitating the sewage after the chemicals had been added to it, but it flowed onwards to the first subsiding tank, which was 40 feet long and 30 feet wide, and from this it passed through the openings of a cross wall into a second subsiding tank 60 feet long and 30 feet wide, from which it escaped by a weir a little under the surface of the liquid, into an outfall channel nearly a mile long, which conveyed it to the River Nene. The subsiding tanks had an average depth of five feet, but the bottoms of them sloped from the sides to the centre, where there was a gutter with an Archimedian screw for driving forward the precipitate to a central well, from which it was lifted by an endless chain of buckets. Each set of tanks worked a fortnight before the sludge was removed, and it was conveyed into properly prepared pits, where it was consolidated by mixing it with the town refuse. In this manner about 7,000 tons of manure were annually produced, and sold for 1s. 9d. per load. The quantity of chemicals daily used were from 60 to 70 lbs. of solid chloride of iron, and from 10 to 12 bushels of lime. Dr. Letheby investigated the process for the Town Commissioners, and we gather from his published report that he recommended an entirely different method of working. "The chloride of iron," he said, "should be dissolved in the water and allowed to run by a graduated stream into the sewage before it reaches the lime. A contrivance should also be used for effecting a perfect mixture of the iron solution with the sewage. This having been accomplished, the sewage should then receive its dose of lime-liquor, and be again well agitated, so as to be thoroughly mixed. In this manner a heavy clotty precipitate will be produced which will rapidly fall in the subsiding tanks, and leave the supernatant liquor perfectly clear and inoffensive. The proportions of chloride of iron and lime should be about 4·5 grains of the former, and from 14 to 15 grains of the latter per gallon of sewage, and the quantities should be so regulated as that the supernatant liquor at the outfall shall be clear, colourless, and but faintly alkaline." This improvement of the process was adopted by the Commissioners, and after it had been in operation for about a year the engineer of the works reported that the results were satisfactory, and that a manure was produced at a cost of 1s. a ton, which was readily saleable at 4s., and which by chemical analysis was valued at 15s.; for, according to Mr. Harris, the analytical chemist of Northampton, it contained 12·1 per cent. of organic matter (with 0·916 nitrogen = 1·112 ammonia), and 0·454 of phosphate of lime. At a later date, in consequence of the difficulty of procuring chloride of iron, the salt was manufactured on the works from native oxide of iron, at a cost of £6 a ton; and it contained about 9,400 grains of the mixed chlorides of iron per gallon. It was used in the proportion of six gallons to a million gallons of sewage, to which about 12 bushels of lime had been previously added. These are in the proportion of only 0·006 of a grain of chloride of iron, and 5·88 grains of lime per gallon, quantities which are manifestly insufficient for the perfect defæcation of the sewage. Nevertheless, at the time the works were visited by the Royal Rivers' Pollution Commissioners, they reported that "the effluent sewage, after a flow of a mile and a-half through a culvert, in which it becomes mixed with about one-sixth of its volume of spring water, is discharged into the River *Nen*, in a nearly clear and apparently innocuous condition. We examined the stream for about one-third of a mile below the outfall, and could perceive no sewer fungus or other sign of sewage pollution." In their opinion, however, the decomposition was merely delayed, as the effluent sewage water contained about 1·245 grains of organic nitrogen. At a subsequent visit to the works, in the month of April of the present year, we found that the sewage was treated in the following manner:—The present population of Northampton is about 40,000, and the sewage amounts to about a million gallons a-day. Instead of being precipitated with chloride of iron and lime it is defæcated with crude sulphate of alumina and iron made from a ferruginous clay and sulphuric acid. Two tons of clay are mixed with three cwt. of crude sulphuric acid, of chamber strength. The mixture is effected in wooden troughs, and as there are six of these troughs, one being almost entirely used out daily, the materials stand in chemical contact for about a week. It is then fit for use, and is diluted with water by placing it in another trough, set upon an incline, and having two cross breaks for checking the flow of the water, which runs into it at the rate of five or six gallons a minute. The dilution is effected by hand labour assisted by a shovel, and the crude chemicals are carried forward into the sewage as it enters the works. There is no contrivance for agitating the sewage before it enters the subsiding tanks, and hence there is but an imperfect flocculation of the suspended matters; besides which, the acid of the chemicals acts upon the carbonates of the sewage and produces a notable effervescence, thereby causing the suspended matters to rise and form a thick scum. This accumulates to a large extent in the first subsiding tank, and is kept back by cross walls with floating planks. From this tank it passes over a weir into the second subsiding tank, already described, and which has alternating cross walls that reach nearly to the end. By this means the sewage is made to take a circuitous route before it passes over the weir into the covered outfall channel, which carries it for rather more than a mile, and then discharges it into the river. At the time of our visit about 15 cwt. of the sulphated ferruginous compound were used to the million gallons of sewage per day, and it was evident that it eventually defæcated the sewage very effectually, for the effluent water was remarkably clear and inoffensive, and gave the following chemical results:—

Constituents per gallon.	Raw sewage	Effluent water from 1st Tank.	Effluent water from Outfall.
	Grains.	Grains.	Grains.
Solid matter in solution -	73·60	70·16	70·65
Chloride of sodium -	18·39	17·78	17·32
Organic matter - -	18·16	15·62	12·81
Ammonia - - -	4·980	4·190	3·247
Ditto organic - -	0·313	0·233	0·200
Oxygen required to oxydise - -	2·265	1·980	1·243
Matter in suspension -	13·85	4·97	1·74
Organic matter - -	8·48	2·91	1·11
Mineral ditto - -	5·37	2·06	0·63

These samples were taken continuously over a period of twenty-four hours; and the examination of the river below the outfall showed that the results must have been generally very effective, for the bed of the stream was quite free from sewage matters, the aquatic vegetation was clean and healthy, and the fish were abundant. It is possible, however, that occasionally, as the process is entirely managed by hand labour, the sewage might not be thoroughly disinfected, and therefore it was considered advisable to improve the works by a more perfect system of machinery. At present, about 400 tons of solid matter are removed from the subsiding tanks every week, and these, with about 48 tons of sifted ashes, and 20 tons of the burnt refuse called soft core, are made into a compost which sells for 3s. a ton, thereby realising about £600 a-year.

At Stroud, in Gloucestershire, the sewage is treated with crude sulphate of alumina and iron obtained by adding 120 lbs. of sulphuric acid to 6 cwt. of powdered clay, and allowing the mixture to stand for several days. The process is known as Dr. Bird's, and the sewage works are managed by a private company. The population of the place is about 37,000, but only from 150,000 to 200,000 gallons of sewage are dealt with by the Company daily, and these are mixed with the above-mentioned quantity of sulphated clay, the proportion being from 28 to 37 grains per gallon, and this is regulated in its delivery by two small water-wheels, which are turned by the sewage itself. The material falls into the sewage immediately before it enters the settling tanks, and the effluent water is filtered through three coke filters before it is discharged from the works. In this manner the whole of the suspended matters are removed from the sewage as well as a large portion of the dissolved organic matter. The precipitate is dried and then mixed with sulphate of ammonia and phosphate of lime, by which means a valuable manure is obtained.

Dr. Anderson, of Coventry, has lately recommended crude sulphate of alumina with lime for the precipitation of the sewage of that city. He produces the sulphate by adding one part of common sulphuric acid to two parts of ordinary clay, and then mixing it with its own bulk of water. The materials are allowed to stand in a warm place until they appear white upon the surface, which is the sign of proper chemical combination. They are then used in the proportion of one pound of the sulphated mixture to every one hundred gallons of sewage, and, after being well agitated, they are precipitated with a quarter of a pound of lime, previously slaked and diluted with water. Instead of working the depositing tanks in the usual manner, by a constant flow of sewage, he recommends that the tanks should be sufficiently large to hold a day's sewage, and that when the precipitating agents have been added, and the sewage has been well stirred, it should remain at rest for twenty-four hours, in order that the precipitate may entirely subside. He then draws off the clear supernatant water, and removes the precipitate. In our own experiments with the material, we found that it defecated the sewage in a very satisfactory manner, and yielded a good precipitate. The process has been recently tried on a large scale at Coventry by Dr. Anderson, who has made use of one of the tanks at the sewage works of the town. The tank contained 100,000 gallons of sewage on each occasion, and these were treated with nine and a-half hundredweight of the sulphated material, which, after thorough agitation, was precipitated with one and three-quarters of a hundredweight of lime, previously slaked. The mixture was allowed to stand for twenty-four hours, when it yielded a clear supernatant liquid, which was analysed for the corporation by Dr. Odling. He found that a large portion of the dissolved organic matter, especially that which is rich in nitrogen was removed. The following, in fact, were the chief constituents of the raw sewage and the effluent water:—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	42·77	56·28
Chloride of sodium . .	7·58	5·95
Organic matter . . .	8·33	6·30
Ammonia	0·77	0·84
Ditto organic . . .	4·00	0·77
Matters in suspension . .	89·74	1·61
Organic matter . . .	51·66	0·91
Mineral ditto . . .	38·08	0·70

In another experiment the effluent water was analysed by Dr. Voelcker, who found that it contained 62·51 grains of soluble matter per gallon, and of this quantity 9·31 were combustible (organic, &c.) Besides which, it contained 1·74 grains of suspended matter, 0·3 of which was organic matter. Dr. Voelcker says of it that, "It is so thoroughly deprived of obnoxious impurities, that, in my opinion, it may be discharged into a running stream or water course without risk of creating a nuisance."

Dr. Anderson calculates, from his experiments on the night and day sewage of Coventry, that about twenty-two tons of dry manure will be obtained from every million gallons of sewage. The manure has been carefully analysed by both Dr. Voelcker and Dr. Odling, and the following was its composition on three occasions:—

Constituents per cent.	Dr. Voelcker.		Dr. Odling.
Moisture	12·01	15·70	20·16
Organic matter . . .	26·89	31·86	22·98
Bone phosphate . .	2·60	2·55	2·20
Other mineral salts . .	6·61	10·33	16·47
Siliceous matter and clay .	51·89	39·56	38·19
Total . . .	100·00	100·00	100·00
Ammonia from Organic matter . .	1·39	1·22	1·41

According to Dr. Voelcker, the two samples have practically the same commercial value, and "will probably find a steady sale at about 30s. a ton." Dr. Anderson has gone very fully into the subject of cost in working his process, and he says that the total expense of producing a ton of manure from the sewage is eleven shillings—7s. 6d. being for the chemicals, and 3s. 6d. for labour, &c.; and for the sewage of Coventry, which amounts to about 1,500,000 gallons a day, the sum required for the erection of works would be about £7,000.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

DECEMBER 5TH, 1870.

JOHN GAY, Esq., President.

INCONTINENCE OF URINE, TREATED BY BELLADONNA.

MR. STREETER related a case of "Nocturnal Incontinence of Urine in a young lady, aged seventeen years, which had existed for four years," and which had been arrested by tincture of belladonna in five drop doses, three times daily; the dose was subsequently reduced to two drops, and Mr. Streeter believes the cure to be now complete.

MR. DE MERIC could testify to the value of tincture of belladonna in the incontinence of urine in children; he gave this remedy in as small a dose as possible, as he did not like giving such powerful medicine to young children. In one family, of four children, every one was affected with nocturnal incontinence, here belladonna was found a good remedy.

In reply to the PRESIDENT, Mr. STREETER could not say how many drops of the tincture would be equal to a grain of the extract, the tincture he used had been kept for seven years. He did not think there was paralysis of the neck of the bladder in these cases, the affection often occurred in strumous children, and Mr. Streeter had found iodine set free from iodide of potassium by a feeble acid, as for example by the slight excess of acid in the spiritus ether is nitrosi, a useful remedy, some vinum ferri might be given with this form of iodine.

MR. HENRY SMITH showed a specimen of a lobulated tumour removed by him two days previously from the back of a healthy man, aged forty-five years. The point of interest was, that three years ago Mr. Smith had removed a simple fatty tumour from the same part of the same patient. In eighteen months' time the tumour returned in the cicatrix, and when removed, was found to be a fibro-fatty tumour, and now the one that had been removed recently, presented all the characters of recurrent fibroid growth.

The PRESIDENT remembered a case where he removed a sebaceous tumour from near the spine of a young man; a small portion, being firmly adherent to the vertebræ, escaped excision. The wound would not heal, and though this remaining portion was afterwards completely excised, the wound still remained open, and was presently filled by a true malignant growth which increased both outwardly and inwardly, and eventually the man died paralysed.

MR. PETER MARSHALL asked for the experience of the Fellows concerning chloral in the treatment of after-pains of labour, his own had not been favourable.

DR. BRUNTON could confirm Mr. Marshall's experiences as to the inutility of chloral in after-pains. In false pains he had found it a very valuable medicine, but in after-pains he would not give ten drops of opium tincture for all the chloral in the world.

DR. BRUNTON then read the paper of the evening,

ON PROLAPSE OF THE FUNIS UMBILICALIS, AND ITS TREATMENT BY THE POSTURAL METHOD.

The Author reviewed the method of treatment advocated in obstetric works, and showed that all of them were deficient in applicability, and in good results when compared with the postural method. He reviewed the difficulties that stood in the way of the ordinary method, and showed how absurd it was to think of carrying about an instrument for the reduction of the prolapse, when that accident occurred about once in 276 confinements. He showed how the postural method was, in accordance with the principles of common sense, always applicable, the hand was the only instrument required, there was no danger to the mother, as in version, and out of ten cases thus treated by him, eight were born alive, of the two that were dead, one died before he arrived, and in the other case there was an extensive disease of the placenta. The operation consists in altering the direction of the uterine axis or plane, which is downwards and backwards, when the mother lies on her back, and nearly level when she is in the usual obstetric position, by placing the mother on her hands and knees in the attitude of an Eastern worshipper, the axis is made to pass upwards and backwards, then the cord can be returned by the hand during the intervals of pain or by its own weight, it slips up beyond the head—the fingers are made to irritate the os uteri by rotation till pain comes on, then the lower segment of the uterus clutches the head or presenting part firmly and no prolapse occurs. The difficulty being thus overcome, the patient can now assume the usual obstetric position. Dr. Brunton showed some of the instruments usually employed for the reduction of the cord. He illustrated his subject by drawings, and suggested a modification of the postural method by applying the same principle, the action of gravity, in the usual obstetric position, when the uterine plane had been altered by propping up the pelvis by pillows, so as to give the uterine plane an inclination by which the cord might slip up. Dr. Brunton had not seen the postural method described in the manuals of obstetrics, except cursorily, as the knee-elbow position was the method more generally known, and followed infant mortality in cases of prolapsus funis would be reduced to a minimum.

DR. ROUTH said he believed that it was at one of the meetings of the British Medical Association, that he heard the late Sir James Simpson say that the treatment of prolapsed funis by the postural method originated with Dr. Hamilton, of Edinboro'. Dr. Routh was content to use merely the postural method without any aid from the fingers, and had been uniformly successful. In one case the patient had convulsions, and these were brought on by the slightest touch of the hand in the vagina, here on placing the patient on the knees and elbows, not only did the funis return, but the convulsions also ceased.

THE MEDICAL SOCIETY OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, DEC. 14TH.

Dr. CHARLES A. CAMERON, Professor of Hygiene in the Royal College of Surgeons, and Analyst to the City of Dublin, read a paper

ON THE DISEASES OF ANIMALS USED AS FOOD, THE MALADIES IN MAN OCCASIONED BY THE USE OF DISEASED MEAT, AND THE SYSTEM OF MEAT INSPECTION ORGANIZED IN DUBLIN.

In Ireland the epizootic which is most prevalent, is contagious pleuro-pneumonia, or lung distemper. About eight or ten per cent. of the dairy stock of Dublin, are annually carried off by this disease. Professor Cameron described at considerable length the symptoms of this disease, and the *post-mortem* appearances. In healthy oxen, the lungs weigh only about eleven or twelve pounds, but in lung distemper they attain weights varying from twenty to seventy pounds. In one case Dr. Cameron found them to amount to one hundred pounds. A specimen was exhibited weighing above seventy pounds. The whole of one lung and a large portion of the other, were hepatized, and presented an appearance like sienna marble. Enormous amounts of purulent matter occur sometimes in the lungs; on many occasions, about one gallon of it was found in those of a cow. Dairymen cannot be convinced of the contagious nature of this disease, and it is only under compulsion that they can be induced to disinfect their premises, after infected animals have been removed from them. The insanitary conditions of dairy yards, were also forcibly pointed out. Amongst other contagious diseases affecting Irish live stock, Dr. Cameron describes that termed the soldier in pigs, which closely resembles scarlatina. The poison of anthrax affects all the farm animals. It is the cause of the so-called splenic apoplexy (the *maladie de sang*) of the French veterinary; the "black leg," or "quarter evil" of calves, and young cattle, the glass-anthrax of swine, the "broxy" of sheep, the carbuncular cynanche, or anthracoid angina, the hæmorrhoidal anthrax and the gangrenous erysipelas of pigs. Panzootic apthæ affects pigs, sheep, and swine. Eczema, epizootica, or foot and mouth disease, was prevalent last year in Dublin, but assumed a mild type. Variolous diseases affect sheep and oxen, but not swine. Dr. Cameron gave an account of his experience of the effect upon man produced by the use of diseased meat. After quoting various writers who affirmed, or denied the dangerous properties of the flesh of diseased animals, he described a number of cases of disease, and which came under his own observation, and which were undoubtedly due to the use of flesh, which was not putrid, but which had the appearances of being diseased. Choleraic diarrhœa was the common symptom present in all these cases. Attention was drawn to the very greatly increased mortality from phlegmons in these countries since the introduction of pleuro-pneumonia in 1841; and stress

was laid upon Dr. Livingstone's statement, that in South Africa the use of the flesh of oxen affected with pleuro-pneumonia produced fatal carbuncular maladies. Dr. Cameron explained the machinery which, under his directions, restricts the traffic in unsound flesh, fish, and vegetables in Dublin. Four policemen are employed as animal-food Inspectors under the directions of a "Deputy Clerk of the Markets." The five officers are commissioned as Inspectors of Nuisances under the Sanitary Act of 1866, and they are all paid by the corporation. Eight "Sanitary Sergeants" also assist in this matter, and the whole force (numbering 1,100 men) have general directions to aid in the detection of sick cattle, unsound fruit, or fish, &c. During the present year, nearly 50,000 pounds of diseased and unsound meat have been condemned monthly, and several persons connected with the ownership of it, have been imprisoned and fined. All doubtful cases of disease, are referred to Dr. Cameron, and the prosecutions are undertaken upon his certificates.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 21, 1870.

SMALL-POX IN LONDON.

Last week this subject occupied the attention of the Epidemiological Society, at which Dr. Seaton made some important statements. He considered the present epidemic might have been expected, as London generally suffered from an outbreak every third year. There had been epidemics of small-pox in London in the years 1851-2, 1855-6, 1859-60, 1863-4, 1866-7, and this of 1869-70. In other large towns an interval of four or five years might occur; but in London, the accumulation of susceptible individuals was so rapid, that the outbreaks occurred more frequently.

The present outbreak is chiefly confined to the East End, because there vaccination has been neglected.

Some unions have been undergoing reconstruction, or the process of amalgamation has been going on, and thus the permanent arrangements for carrying out the Vaccination Act have been postponed. Further, there have been difficulties about the fund to which the expenses were to be made chargeable. And so it comes to pass that two precious years have been in some districts wasted. The worst unions seem to be Bethnal Green and Mile End Old Town, and in these some of the Guardians have abetted the fanatical opponents of Jenner's beneficent discovery. Nearly half the mortality from the small-pox epidemic has fallen upon these two parishes,—an awful lesson to the Guardians who have neglected their duty and encouraged the people to resist the law.

Dr. Seaton told the Society that out of 281 deaths in nine weeks from the small-pox, 135 had taken place in those two unhappy parishes. When an inspector was appointed, he received a list of 4,000 children about whom no return had been made. It was then publicly asserted that the parents of that number objected to have the operation performed; but such an assertion is most unreasonable. Neglect, not resistance, is to be seen here, and the public will consider the Guardians to blame. For our part, we think some machinery might be devised to instruct parents on the importance of the subject. It would be far better to vaccinate the thousands whose parents would not object if the object were explained properly, than to prosecute the half dozen vaccina-phobiacs who are unable to reason on the matter.

Having mentioned the worst unions, we may also name the best,—again on Dr. Seaton's authority. He predicted to the Epidemiological Society that, when the epidemic is over, Poplar, St. Luke's, and the Clerkenwell division, Holborn, will be found to have reaped the benefit of their prudence.

In former epidemics, Poplar has suffered severely. In this it has only contributed 11 deaths to the 281. In St. Luke's, the mortality has been also small, though formerly it suffered in the highest degree.

Dr. Seaton also referred to Paris, which he visited just before the siege, and he attributed the epidemic of this year to an "appalling" neglect of vaccination. For twenty years London had not had in a quarter as many deaths from small-pox as Paris was said to have had per week.

Before leaving this subject, we may advert to the rapid filling up of the temporary hospital provided at Hampstead by the Asylums Board, and the enlargement now taking place. Sixty more beds will be ready in three weeks, making a total of 190; and the permanent hospitals at Homerton and Stockwell are being pushed forward as fast as possible.

There have been nine deaths in the Hampstead Hospital; seven certainly unvaccinated, and the other two could not be certainly ascertained. It is to be hoped the increasing mortality will rouse the public to the importance of vaccination, and that we shall hear no more of the foolish fanatics who seem to have no care for the lives lost through neglect of a trifling operation, from which they fancy some injury has now and then arisen. Well would it be if their credulity were manifested in some more sensible way.

Notes on Current Topics.

About the War and Wounded

The following are the German arrangements for treating the wounded :—There is a staff at head-quarters of medical officers, with assistants. Every army *corps* has three sanitary detachments, and when a division goes into action, one of these sets out immediately. On an average—some being greater and some less—each detachment is composed of about 120 soldiers to carry the wounded, and 16 orderlies, who act as dressers sometimes. Half-a-dozen waggons, with stretchers and straw inside, accompany it to the field. As well as its own sanitary detachment, a division can have the use of either or both of the two others attached to the same *corps*. They bring in any wounded man who can be reached in the heat of the battle. Four orderlies, with a stretcher, proceed to the ground, one of them having a bag round his neck, containing tourniquets, bandages, plaister, and other appliances, if it was necessary to staunch the wound temporarily before removing the patient to the dressing-place, where, on his arrival, if immediate treatment was indispensible, he was treated on the spot ; if not, he was removed in a waggon to one of the field lazarettes, or hospitals. In addition to the above arrangements, every field lazarette has the use of ten ambulance carriages.

* * *

It must be very difficult to form an estimate of the numbers of the wounded lately either round Paris or on the Loire. The condition of the interior of Paris is still less known, and the contradictions to be daily met with in the papers only illustrate how wide the guesses are. It seems certain, however, that the numbers have been very great ; and when thousands are put *hors de combat*, there must be hundreds whose wounds are serious. As to the food supplies of Paris, still less can be actually known, and we shall therefore make no attempt to reconcile the opposing statements, for we place no confidence in any. A good many editors must possess strong notions as to the gullibility of their readers, seeing the exact information they profess to have obtained by *ballon monté*.

* * *

The Septuagenarian Ricord has carried high the banner of the Profession. An eye-witness says, that in the sortie of the 30th ult., he amazed everybody by his prolonged exertions and his "ubiquity." The same praise may be paid, and will be, to many others of our *confrères*.

* * *

Dr. Heyfelder, of St. Petersburgh, has, at Nieuweid, 150 German wounded under his care in huts and tents.

* * *

While so many are rivalling each other in doing good, it is idle to deny that the Geneva Convention has not succeeded so well as was expected, and the outcry for its revision will probably grow louder and louder. It is easy enough now-a-days to declare treaties void. Will it be as easy to amend the one effort to ameliorate the sufferings caused by war ?

* * *

We have already spoken of the numerous deaths of surgeons who are freely expending their lives to aid the sick and wounded. The untimely death of Dr. Davis—*le bon docteur noir* as the poor starving peasants called him—is but an incident constantly repeated, and of which many more will be told.

In the same week died Dr. Thomas at Sedan, exhausted by the toil to which he had given himself up.

The infamous murder of Dr. Debaudre has also been chronicled in these columns. The chief physician of the Sedan ambulances, Dr. Duplessy, delivered the following address over his grave :—

"Citizens,—A youth of twenty-five years—Dr. Debaudre, of the International Association, bearing our inviolable badge—whilst fulfilling a medical duty, has been murdered ! It is our painful duty to bury the victim of this infamous action. What a cruel irony of the Lord of Hosts, whom tyrants invoke ! This victim was for ever ready to comfort, to heal, even the man who deliberately, in a dastardly manner, has killed him, without caring for the signal of this poor physician, who was waving his handkerchief, without looking at his pass—without taking the trouble to observe our badge ! The murderer has fired on the Red Cross. I protest, as a physician, as the delegate of the International Red Cross Association of Brussels, against this barbarous deed, which will find a painful echo in every heart. Do we not suffer enough, then, already—far from our families, far from our friends, far from our children ? Do we not die quickly enough then—of typhus, of infection, of hospital gangrene, as is proved by our lamented colleague, Thomas, and by so many others, whose martyrology would be too long ? Must we whilst fulfilling our duties as volunteers of benevolence, whilst carrying our help far and near, have to fear to be shot as are shot wild beasts ? If the Geneva Convention is a dead letter let it be told openly ! Then we shall arm ourselves—we also, we who now carry the weapon which heals those who are wounded by weapons ! It would ill become us to speak of vengeance over a grave, for we are men of peace, and already there are but too many victims in this dreadful war, against which every man who has a heart protests. We hope that justice will be done. Whoever the murderer is, he will have to bear the penalty of a crime against humanity. His conscience, if it be accessible to remorse, will cry out to him, 'Murderer, your bullet has struck an inoffensive man ! Murderer, you have taken aim against a neutral ! Murderer, you have killed, pointblank, a physician, an inviolable man, a benevolent man, who was without means of defence, whose mission it was to brave death in order to bring life to you !' And you, unfortunate colleague, had you not suffered enough in prison, exile for a sacred cause, under a cursed government ? Was it our destiny, when you left us, full of life, to meet your wife in tears, near your corpse bathed in blood ? Farewell, my colleague ! Farewell!"

The Medical Administration of the Turkish Army.

Doctors of the Imperial School of Medicine for the Army are divided into three groups, and have the titles of chief doctor, doctor, aud assistant doctor (*médicins-en-chef*, *médicins*, and *aide-médicins*).

Médicins-en-chef form two classes, with the rank of Colonel for the former, and Lieutenant-Colonel for the latter.

The *Médicins* form three classes, the first having the rank of Major, the second that of Lieutenant-Major, and the third that of Sub-Lieutenant-Major. The *aides-médicin* have the rank of Captain.

There are besides two classes of medical inspectors having the rank of *Général de brigade* in the first class, and of *Colonels* in the second, Each of these classes consist of three members.

Apothecaries from the Imperial School of Medicine are divided into three groups, with the titles of Apothecary-in-chief, Apothecary, and Assistant Apothecary.

There are two classes of Apothecaries-in-chief :—1st. Apothecaries-in-chief of the first class, having the rank of

Lieutenant-Colonel; 2nd. Apothecaries-in-chief of the second class, having the rank of Major.

The Apothecaries are divided into three classes, and have respectively the ranks of Lieutenant-Major; 2nd, Sous-Lieutenant-Major; 3rd. Captain. The Assistant Apothecaries have the rank of Lieutenant.

Leicester.

It is proposed to establish an hospital for small-pox and scarlet fever at Leicester, as these diseases are not admissible into the existing institutions, and they are quite epidemic. Scarlet fever is said, at present, to be prevalent in a very malignant form; and the sanitary condition of the town generally is described as very bad.

Detection of Methylated Spirit.

In the course of a paper recently presented to the Royal Society of London by Dr. I. Emerson Reynolds, Analyst to the Royal Dublin Society, an easy mode of detecting acetone, is described as resulting from some researches "on a new class of colloid bodies—mercuric compounds of certain retones." Acetone being invariably present in considerable proportion in the wood spirit of commerce, the reaction below described becomes virtually a test for the presence of pyroxilic spirit in any mixture. The ordinary "methylated spirit" of commerce is such a mixture with pure alcohol; we are, therefore, now in a position to detect the presence of this methylated spirit, by means of the following characteristic reactions of its invariable constituent acetone. 400 c. c. of the suspected spirit are to be placed in a retort, and rapidly distilled until 100 c. c. have passed over. The distillate should be diluted with its own volume of distilled water, and the mixture very gently warmed with addition of a few cubic centimetres of caustic potash solution. On cautious addition of solution of mercuric chloride, the mercuric oxide at first thrown down is quickly redissolved, if acetone be present. Any excess of the mercury salt must be carefully avoided, as a white insoluble compound is then formed. The alkaline liquid containing mercury, must now be filtered clear, and then divided into two portions. One part is to be violently boiled for some time, a yellowish-white gelatinous precipitate will suddenly make its appearance if the resolution of oxide of mercury in the first instance was due to the presence of acetone. In the second portion dilute acetic acid, when added in slight excess, should produce a bulky gelatinous white precipitate, containing, when carefully washed and dried, between 78 and 79 per cent. of mercury. Though acetic aldehyde combines with mercury, it does not yield a solution possessing the above character. In examining medicinal tinctures by the new method, it is absolutely necessary to test the suspected sample against a specimen of the particular kind of tincture of known purity. Certain volatile oils extracted by spirit from plants pass over during distillation, of course tincturing, and by their action on the mercuric oxide, in presence of caustic alkali, might mislead an inexperienced operator. Contrast of the pure tincture with a suspected sample guards against the source of error.

Professor Bloxam, as recorded in our last issue, succeeds the late lamented Professor Miller in the Chair of Chemistry at King's College.

Persistent Delusions in Small-Pox.

An interesting case communicated by Dr. Mathew, appears in the last issue of the *Indian Medical Gazette*, of the occurrence of hallucinations as a persistent symptom of small-pox.

"During the primary stage of eruption, the patient, as not unusually happens, without being actually delirious, was troubled with delusions of various kinds. Outside his hallucination, the patient answered all questions intelligently and sensibly. The chief among my patient's delusions was, that a photographic amateur, who had previously lodged in the room immediately above this, had spent a whole day photographing him through the ceiling. Another was, that a sore throat, from which he suffered, was the result of some magnetic machination of a band of spiritualists. After a few days he ceased to allude to these delusions; the disease ran through its regular stages favourably, and in due time he became perfectly convalescent. Then, to my great surprise, on my chancing to mention his early fancies, he declared that it would be his first business on getting out of doors, to hunt up the spiritualists and punish the photographer. Some days later, when able to sit up, he acknowledged that he might have been mistaken as to the former, but not as to the latter, though he could not explain how a photograph could be taken through the ceiling. The delusion ultimately passed away, but not before he was so far recovered as to be able to walk in the verandah. He must have been very tired at the time, for he told me, that having failed to stop the operation by covering his face with a handkerchief, he wrote, as a last resource, the following appeal to his tormentor on a page in his note-book, and held it up for the photographer's perusal:—

"Will you please understand that I had no sleep for forty-eight hours, and very little nourishment; so I am unable to sustain the present species of entertainment for the present."

Brighton Museum.

The valuable museum at Brighton is being utilised by the delivery of conversational lectures in the geological, entomological, antiquarian, economical, and sanitary departments. The object is to explain the specimens, and we learn from the *Brighton Examiner* that the plan has been well carried out and has proved very attractive.

The Edinburgh Female Medicals.

The London evening newspapers—the most interesting organ of its party, the *Globe*—writes as follows on this subject:—

"The students attending the Surgeons' Hall at Edinburgh who wish to exclude the ladies have, at length, dropped rowdy demonstrations and addressed their complaint in sober language to the heads of the college. Their main grievance is that 'the presence of women at the classes of anatomy and surgery and in the dissecting-room of the College, gives rise to various feelings which tend to distract the attention of the students.' This is quite a fair argument; and had it been properly conveyed at the beginning of the session, we have little doubt that arrangements would have been adopted for the instruction of male and female students in separate class-rooms. But see what comes of rowdyism! Who will listen to the petitioners' invocation of 'delicacy' after the riot of the 18th of November, in which four 'gentlemen' were

arrested as ringleaders, and for which they have since done penance? With what consistency can they appeal to the 'sense of decorum' after their disgraceful conduct towards the lady students? If any one in those 'mixed classes,' of which the petitioners complain, should feel the awkwardness of the position, it should be the lecturer himself. But that functionary makes no such avowal: nay, rather, he thinks the presence of ladies should put 'gentlemen' on the point of honour to attend to nothing but the purely scientific aspect of the subject in hand. *Mundis omnia munda!* Neither ladies nor lecturers are conscious of 'indelicacy' or 'breach of decorum.' Can it be that the unruly students are 'nice' only upon Dean Swift's principle, because they are 'nasty.'"

Medical Reform.

Dr. Rumsey has written a letter in the *Journal of the British Association*, which has been answered by Dr. Waters, of Chester, who was furnished with proofs for the purpose. Ditto with the rejoinder. Dr. Waters, with all his advantage as an official of the Association is, of course, just nowhere against such a State Mediciner as Rumsey, who, however, lets off the Chairman of the Direct Representation Committee very easily. The Chairman asserts that the votes of the general meetings represent the Association. Everyone knows better, and we have repeatedly pointed out that the only time a vote was fairly taken the Chairman and his Committee were thrown overboard. But the next day the wire-pullers got a rider added in a thinly attended meeting of their own clique, when no one but those whipped-up for the occasion dreamed that the subject would be resumed. This is a blot on the whole Association which suffered itself to be thus degraded, and Dr. Rumsey might very well have burnt it into the memory of those who will read his letters when they pass over others.

Dr. Waters took offence at the expression of "trade-union" as applied to the Association. Dr. Rumsey did not apply it to the Association, and explains this, even calling the notion a "monstrous" one, and saying he neither holds nor has even intimated it.

What a queer turn for the controversy to take. If the Association is not a "trade-union," and if it does not exhibit "trade-union proclivities," will Dr. Waters kindly tell us what it is? and what "proclivities" are concealed under its striking resemblance to a weak "trade-union?"

The Epizootic at the Cattle Show.

The outbreak of foot and mouth disease at the Agricultural Hall is a calamity that might have been, to some degree, expected. We were glad to note the active measures adopted by the Privy Council, and we hope the relaxation of the restrictions at first imposed may not be followed by any spread of the disease. The relaxations in question seem to have gone no further than is reasonable; and certainly the country had a right to expect that the powers with which the Privy Council is armed should be used on such an occasion. With the disease so common in London dairies, it might have been well to consider whether no means could have been adopted to prevent the infection being conveyed by persons connected with them likely to visit the show.

Dr. Russell has been appointed to the Chemical Chair at St. Bartholomew's Hospital. Leaving St. Mary's for this appointment, he thus follows the career of the late Dr. Matthiessen, whom he succeeded at St. Mary's.

Science in Liverpool.

A conference of gentleman interested in scientific education was held in the Royal Institution, Liverpool, on Tuesday, the 6th inst., and passed unanimously a resolution declaring the advisability of establishing a Science College in that town, the cost of which was estimated at about £50,000. A committee was appointed to take steps with a view of carrying out the object.

English Medical Students.

From the returns which have just been completed for the Government Inspectors of Anatomical Schools in the metropolis and in the provinces it appears that at the eleven recognised hospitals in London there are at the present time 1,324 gentlemen pursuing their professional studies, all of whom, in pursuance of the regulations of the London College of Surgeons and other examining bodies, have passed a preliminary examination in arts, &c., and many add to their other qualifications "B.A." and "M.A." Oxon., Cantab., Lond., &c At the eight recognized provincial schools there are 378 gentlemen pursuing their anatomical studies, making, with those in London, a total of 1,702, being an increase over the corresponding period last year of 141. For the preliminary examination in arts, &c., for the diplomas of Fellowship and Membership of the London College of Surgeons, commencing on the 20th inst., and which is conducted by the staff of the College of Preceptors, there are already 350 candidates.

A Hint for Mr. Mill and the Small Family Party.

The record of vital statistics of the State of Massachusetts for the past year, developes some interesting facts. There were twice as many American marriages as foreign ones. There were double the number of births to foreigners, that there were to natives. In Boston the proportion was seven births to the former and three to the latter. It is not hard we think to tell the cause for this.

The Suggestions of the Conference of Irish Licensing Bodies.

We understand that these suggestions, which we printed at length in our last issue have been under the consideration of the Council of the Royal College of Surgeons and of the Fellows of the College of Physicians. The Council of the College of Surgeons have expressed their opinion that a measure founded on the suggested principles would not be likely to prove satisfactory. The College of Physicians, on the other hand, has adopted and approved of them.

Diaries.

The appearance of diaries, almanacs, and pocket books for 1871, reminds us how soon the present year will have passed away, and brings before us numerous candidates for favour; for professional men really need a good diary, and it is time to choose. We have been using this year Letts's Medical Diary, and have been so satisfied with it, that we intend to employ the same pocket book for 1871. It contains a large number of most useful memoranda to which any practitioner may be glad to turn. One of our colleagues prefers Letts's Appointment Diary, as it provides an hourly arrangement by which punctuality is ensured.

It is just the thing for those who do not care for so large a pocket book as the *medical* one, or do not wish for a regular visiting list, but to keep daily appointments, or lay out their day's work beforehand. For carrying instruments, Letts's Instrument Wallet is most useful, and combines the Diary with it. In one of Letts's Medical Diaries for 1871, already out, we observe spaces for a Diagnostic Record, that in some cases must be very convenient. Altogether, Messrs. Letts, Son and Co., seem to have provided a variety that cannot fail to suit every professional man.

The Irish Unions Apothecary.

Three new candidates have taken the field in the competition for the Irish Apothecary nest-egg, viz.:—Dr. Moore, Member of the Court of Examiners, Apothecaries' Hall, and Medical Officer, South City Dispensary; Dr. Henry Fisher, for the past ten years Proprietor and Manager of the firm of McMahon and Co., Chemists, Limerick; and Dr. Wheeler, of Carrickmacross.

Birmininghham Water.

On the occasion of the visit of the British Association to Birmingham, Dr. Hill read a very able paper on the characteristics of the waters used in the town. The *Food Journal* says, that the revelations then made as to the qualities of the shallow well-waters are such as to shock the feelings of any thoughtful man. The table is too long to quote in full, but a few facts from it will suffice. The total solid impurities per gallon figure in enormous amounts, such as 256, 380, and even 507 grains per gallon; while the organic contamination runs through a rising scale till it reaches the almost incredible figure of 48·16 grains per gallon, in the very water holding 507·92 grains of solid matter in each gallon!

Health of Dublin.

In the Dublin Registration District the births registered during the week ending December 10th amounted to 137. The average number in the corresponding week of the years 1864 to 1869 inclusive, was 153.

The deaths registered during the week were 147. The average number in the corresponding week of the previous six years was 161.

Five deaths from fever were registered, viz.:—1 from typhoid, and 4 from simple continued fever.

Five deaths resulted from whooping-cough and 1 from measles.

Scarlet fever caused 13 deaths, 6 of which occurred in No. 4 South City District.

Six deaths were attributed to diarrhœa.

Bronchitis proved fatal in 33 instances, and pneumonia, or inflammation of the lungs in 7.

Three deaths were ascribed to apoplexy, 2 to paralysis, and 1 to epilepsy.

Seven children died from convulsions.

Four deaths were referred to heart disease.

Three deaths were attributed to liver disease, and 3 to kidney disease.

Eleven deaths resulted from phthisis, or pulmonary consumption and 4 from mesenteric disease.

Two accidental deaths—1 from fractures and 1 from burns—were registered.

London School Board.

The Board has opened its work in a manner to cheer every one. By thirty-two to fourteen, it decided that the chairman shall have no salary. Thus, London is not to make a great job of education. There will never lack men who will be ready to take so honourable a post even if require hard work, and we therefore rejoice that there is a chance for disinterested patriotism open. It is such a fashion to cry out for pay that honour seems likely to go a begging. What nobler thing can a well qualified man, with means do, than give his time to his country? The next business was the election of a chairman. Lord Lawrence was elected, and his administrative abilities and success promise well for the choice. We congratulate his lordship on obtaining the suffrages of his fellow-members of the Board, and on accepting the post without a salary.

Railway Accidents.

Public attention has been so engrossed with the horrors of the war, that there is some danger that the numbers of railway accidents may not be so closely scrutinised as at other times. Not only the several terrible ones that have startled people with their sudden horror, but many minor ones have lately occurred, and will, no doubt, crop up in the law courts in course of time.

Why is not the block system absolutely adopted? It is quite certain that the worst accident of all could not have occurred had it been in operation on that line. It is time to indict for manslaughter directors who refuse to interfere to prevent death by such a simple regulation. To convict a traffic manager and a chairman of a company and send both off to the cells, might effect what remonstrance will not.

Explosions.

Birmingham has seen another explosion. The General Hospital has presented a scene that can only be equalled in these terrible catastrophes, or in those brought about in war. This scene, indeed frankly may be attributed to war, for it was in the preparation of cartridges it took place. Severe burns of various kinds occurred—of course, mostly about the exposed parts of the body. The eyes were, in many cases, destroyed. Falling beams caused fractures and other injuries. The list of dead is probably not yet even complete. Of course, the whole staff of the hospital rendered every assistance possible to the helpless sufferers. Beds had to be placed in the chapel, and cases nearly convalescent were sent away to make room for the sufferers.

Pepsine.

Messrs. M'Master and Hodgson have introduced a preparation under the name of Vinum Pepsinæ Porci, which possesses agreeable qualities, and appears well suited for general use. We have also examined some from the laboratory of Messrs. Bullock and Reynolds, which is of very fine quality. Pepsine may be prepared from the stomach of various animals, but the Pepsinæ Porci is said to be five times stronger than that made by Boudault. Since the introduction of pepsine into Britain by Mr. Squire in 1855, it has held its place in medical practice, and, within the last few years, has been rather extensively used.

The favour it has met with is one instance out of many of the constructive and restorative tendencies of the medicine of the present day.

The National Hospital for the Paralysed and Epileptic has received £1,000 from "W. X."

"R. G. Y." has given a second £1,000 to the Royal Hospital for Incurables, and "B," £500.

"W. R. T." has given a second £1,000 to the Westminster Ophthalmic Hospital.

The Children's Hospital, Birmingham, becomes entitled to £300, under the will of Mr. A. S. Evans.

The next Quarterly Examination of the Royal College of Surgeons in Ireland, will be held on Tuesday, the 10th, and Tuesday, the 24th January, 1871, at Three o'clock, P.M.

Alexis St. Martin, the Canadian who was shot through the stomach, and upon whom Dr. Beaumont experimented, is still living at Dutonsville, Vermont. He is married and has a family.

The poisonous dose of hydrate of chloral has been accidentally tested recently in a London hospital, A patient received in mistake 160 grains of the agent, and recovered with little other effect than a very prolonged sleep.

Sir William Fergusson's proposal for the formation of a collection of surgical instruments and appliances, both ancient and modern, to be added to the Museum of the College of Surgeons has been submitted to the Council by the President and approved.

Dr. Stein, of Dresden, when lecturing lately on the preservation of food, opened a tin canister of meat which had been preserved by him by Apert's method in 1851, and the meat, on examination, was found to be as fresh as when placed in the canister nineteen years ago.

Mr. Thomas Thornton has bequeathed £200 to each of the following institutions,—namely, the Asylum for Idiots, Earlswood; the Orthopædic Hospital; the Royal Hospital for Incurables, Putney; the Hospital for Diseases of the Chest, Victoria Park; and the Brixton, Streatham Hill, &c., Dispensary.

Mr. E. Backhouse, Mr. James Hartley, Mr. G. Spark, Messrs. Backhouse and Co., Messrs. Lambton and Co., Messrs. Woods and Co., and Messrs. Wilson, Bros., have each given £100 to the Sunderland Infirmary Building Fund, and thus cleared off the debt.

The Irish Court of Bankruptcy has been called upon to give judgment as to whether a dentist making sets of artificial teeth for his own patients is or is not a trader. The question arose as to whether a dentist, thus managing his business, came within the provisions of the Bankruptcy Act, or was simply an insolvent.

The Court delivered an elaborate judgment to the effect that a dental surgeon, under the circumstances, is a trader, and liable to the provisions of the Act.

The level of morality and decency, to which a certain class of the American Press has fallen in their attitude towards medical swindling, is painfully illustrated by an account published by the *New York Star*, of the gastronomic bribery to which the Yankee editors unblushingly confess. One of the fed informs us that :—

"*The renowned* Dr. Helmbold last night paid a felicitous compliment to the agency through which his wonderful medicines have been heralded to the world, by giving a dinner to the Press. Amongst those present were the representatives of the New York *Standard;* Associated Press; Press Association; *Journal of Commerce;* New York *Post; Sunday Herald; Sunday Gazette;* Boston *Journal; Republican;* New York *World;* Philadelphia *Ledger; Alta Californian; Commercial Advertiser; Chronicle; Star*, and others.

"The dinner was worthy of the man who can afford the luxury of a six-in-hand team, and who has palatial residences at all the watering places, and a winter palace in New York City. The invincible doctor was then and there put in the field as the candidate of the press for the Presidency, and it was stoutly maintained that a man who had the brains to make a fortune by the use of printers' ink was the man of all others for them to sustain. It was all very well to talk about generals and statesmen, but give us the man who can invigorate a whole nation by his bracing medicines.

"After brilliant speeches, the company adjourned, with three cheers for Dr. Helmbold, and with the hope that the strength of his wonderful Buchu may never grow less."

LONDON EPIDEMICS.

A meeting of the Association of Medical Officers of Health was held at the Scottish Corporation Hall, Crane court, Fleet street, on Saturday the 17th inst., at 7.30 P.M. Dr. Stevenson made some observations on the "Properties of Chloralum." Dr. C. J. B. Aldis read a short paper on "Scarlet Fever for Ten Years in the Parish of St. George, Hanover square." A paper entitled "The Milk-Supply for Towns," was read by Prof. John Gamgee. Dr. Ballard read "Notes of a Case of Pemphigus, following upon inoculation from an eruption upon Milch Cows."

Referring to the epidemics, Mr. Liddell thought that it was of no use to check those diseases by means of disinfectants, as long as the bodies of persons who had died were allowed to remain for days in rooms and houses in which many poor people had to live. This dangerous habit was often practised. There were at present several cases of small-pox in the London Hospital among persons who were first taken in on account of accidents. At a recent meeting of the London Hospital Board he had suggested that there should be also in readiness a shed for the reception of such cases, and he had reason to believe that that suggestion would be carried out.—Dr. Aldis stated that small-pox was extending very much in the district with which he was connected, namely, St. George's, Hanover-square. He thought it was of immense importance that some energetic steps should be taken to provide for the reception of cases of this shocking disease as they occur among the poor, and hoped that the Medical Profession and the public generally would quickly see to it.—Dr. Gibbon considered the suggestion made by Mr. Liddell respecting the permanent erection of sheds in connection with our hospitals very valuable, and hoped that it would

be generally put into practice. Dr. Aldis read a paper on "Scarlet Fever for Ten years in the Parish of St. George, Hanover square," with the view of creating a discussion on the subject rather than advancing anything new respecting it. He considered that every district should have carriages specially fitted up for the conveyance of fever patients to the hospitals, and that the authorities should provide the people with full facilities for disinfecting. He believed that at the present moment much sickness was spread through fever cases being carried in cabs from their homes to the hospital. Isolation was the great secret for the prevention of the spread of either small-pox or scarlatina. Dr. Tripe said that it could not be made too well known that isolation could be very effectually accomplished in a room. The system of isolation in a room he had adopted was to hang sheets, saturated with carbolic acid, across the room, and he found it to be a very good precaution.

SCOTLAND.

EDINBURGH.—The subject of mixed classes has again been raised in connection with a memorial presented to the President of the Royal College of Surgeons by sixty-six students attending the extra-academical lecturers, requesting his influence to procure the removal of the following grievances :—

Firstly—That several of the lecturers at the Royal College of Surgeons have admitted women into their classes without the least endeavour to ascertain the opinion of the male students, and, as now appears, directly contrary to their desire.

Secondly—That the presence of women at the classes of anatomy and surgery, and in the dissecting room of the College, gives rise to various feelings which tend to distract the attention of the students from important subjects of study.

Thirdly—That as the institution of mixed classes had not been determined upon when many of the present students attached themselves to this school of medicine, we are of opinion that those gentlemen who commenced their studies under the old system have suffered a certain breach of contract, inasmuch as a new element has been introduced which would have demanded consideration in their choice of classes.

Fourthly—That the presence of women in the classes of the Royal College of Surgeons has produced and cherished a feeling of discord which threatens to lead to very serious consequences.

The following is the President's reply :—

GENTLEMEN,—I have brought your petition under the notice of the Royal College of Surgeons, and have been instructed to reply that the College is not a teaching body, and though it recognises, and is interested in the success of, all the extra academical classes, it has no direct control over them, and is not responsible for the decisions of the lecturers.

The College, therefore, with every disposition at all times to promote the interests of the students of the Medical School of Edinburgh, cannot interfere with the teachers who have adopted mixed classes ; it can only indicate that the proper quarter to which the petitioners should apply is the Association of Lecturers, who occupy the premises at Surgeons' Hall, and are merely tenants of the College.—I am, your obedient servant, JAMES D. GILLESPIE, M.D.,
President R.C.S.E.

The Royal College will hold a special meeting on an early date to consider a motion, proposed by Dr. Andrew Wood, condemnatory of medical teaching in mixed classes.

THE prevalence of fever in Edinburgh has induced the Town Council to purchase the Canongate old Poor-house for a fever hospital. Fortunately, little or no alterations require to be made in the wards, so that patients will be admitted at once. Without any overcrowding, 120 cases can be easily accommodated. The want of accommodation in the University Buildings, especially felt by the Professors of Anatomy and Chemistry, will soon, it is hoped, be obviated. The sale of the Infirmary Buildings to the University authorities, though not formally ratified, may be regarded as virtually concluded. The purchase price is over £20,000.

Literature.

ST. THOMAS'S HOSPITAL REPORTS.*

THE first article in this volume is from the pen of Dr. W. H. Stone, and contains a short but interesting account of Old St. Thomas's from its foundation, in the year 1215, up to the modern days of the Coopers, Green, Travers, and South. We are treated to some of the formulæ of the old pharmacopœia of the hospital, and learn how the aqua limacum or snail-water might be economically prepared for hospital use.

Earthworms enter largely into this water, and we would commend it to the consideration of homœopaths as likely to prove a valuable vermifuge in their hands.

Modern St. Thomas's appears to great advantage in Dr. Peacock's able remarks on the different kinds of Pulmonary Consumption. Acute constitutional phthisis is well described, and then illustrated by well selected cases. In Case I. the symptoms appeared first on May 14th, and on June 1st, the young lady died. Both lungs were found infiltrated with miliary tubercles. This case was fatal by by apnœa ; another case also of a female, aged twenty-four, was fatal in about the same period of time as the first, from capillary bronchitis, and both lungs contained a copious deposit of small miliary tubercles. The article concludes with valuable practical remarks on the treatment of phthisis by climate, diet, and medicine. Among the numerous other contributions to the volume of reports, may be mentioned the two papers of Dr. J. S. Bristowe, the first "On the Mechanism of Articulate Speech," the other "On Disease of the Skin, due to the Growth of Vegetable Parasites."

Mr. Barwell contributes an essay "on Infantile Paralysis" and draws a parallel between this kind of paralysis and that due to spinal congestion. The points of difference are pointed out between infantile paralysis and the paralysis of spinal congestion in two parallel columns. Mr. Barwell has met with good success, in treating infantile paralysis by the injection of a solution of strychnine, having frequently injected in quite young children, in fact in babies, five and even seven half minims of strychnia solution of which each half-minim contains 1-100th of a grain of the alkaloid. In several cases the action of the strychnine was aided by the use of the constant current. It appears that if a few fibrillæ can be got to respond to the current, others join in, and, becoming themselves regenerated, propagate the influence still further. Mr. Barwell is strong against temporizing and delay in these cases of paralysis in children, a spontaneous cure may come, but if it does not, then hopeless lameness may be the result of delay and inaction.

Dr. Clapton, in his paper "On the Action of Quinine," explains the curative action of this body in ague, on the highly probable hypothesis, that it replaces the animal quinodine which has been destroyed by the ague poison ; the withdrawal of this animal quinodine is the cause of the ague, and not its substitution by some materies morbi generated in the blood. In epilepsy, quinine has been found valuable in averting the fits, given during the period of mental aberration and "fidgetiness" which may precede the epileptic fit. A list of seventy cases is given, illustrating the treatment of epilepsy, by quinine, arsenic, and bromide of potassium.

Among the surgical contributions, we have a paper "On Cases of Lumbar Colotomy" by Mr. Allingham. The results attained in relieving the distress and pain attendant on cancerous affections of the rectum seem remarkably good, life was prolonged, and the patients were unceasingly grateful for the relief afforded by the operation. In one case where the operation was performed for a stricture of the rectum, the patient is able to attend to his business, and suffers very little inconvenience from

* St Thomas's Hospital Reports. New Series. Vol. I. 1870. John Churchill and Sons.

the artificial anus in the loin. It is remarkable that in this case No. 5, a portion of the gut, apparently sigmoid flexure, of the length of five inches, came away as a slough from the wound.

Mr. Allingham's paper is followed by one by Mr. Spencer Wells "On Operations for the Cure of Vaginal Fistulæ"; here the reader has much of Mr. Well's valuable experience, and the various procedures are fully illustrated by well executed woodcuts.

The contribution of Dr. Barnes "On the Pathology of Effusions of Blood in the Peritoneum," with special reference to the so-called retro-uterine hæmatocele, is a most important and instructive paper, after reading which, much light may be gained by most men on cases that may sometimes have rather perplexed them.

The very excellent and practical paper by Mr. Carr Jackson "On Lithotomy." Mr. Jackson aims at safe lithotomy, rather than at brilliant style of operating, he prefers the use of a probe-pointed knife for the section of the prostate, using the pointed knife only for the first incision and section of the urethra as far as the apex of the prostate. Mr. Jackson uses a large staff with bold sweeping curve, and deeply grooved on its posterior aspect.

The Surgical Treatment of Diseases of the Joints is ably dealt with by Mr. Sydney Jones, and Mr. W. W. Wagstaffe furnishes a carefully compiled paper "On the Temperature of Shock in Surgical Cases." The record of the obstetric department of St. Thomas's, by Dr. Gervis, and also those of the medical and surgical cases entered at the hospital, appear to be prepared with great labour and care. Space permits us to notice, that among other contributors of good work to this really excellent volume, are found Dr. Carpenter, of Croydon, who writes "On the Causation of Epidemic Disease." Mr. J. Croft, Dr. L. Sedgwick, Mr. Rainey, Mr. West, Dr. Barker, Dr. F. Churchill and Dr. Ord, who contribute papers "on Surgical, Obstetrical, Physiological, Chemical, and Medical Subjects."

Mr. Solly and Dr. J. Lockhart Clarke, give a very complete account of "a Case of Locomotor Ataxy." The *post-mortem* microscopical appearance in the cord, being described and illustrated.

Correspondence.

"A VAN FOR TRANSMISSION OF LUNATICS."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In these days every part of the public service is being critically examined. At one time, a defect is discovered in the military and naval systems of the country, and the heads of these departments are held up to vituperation and all sorts of abuse; at another time, the Civil Service, in its multiform parts, is mentioned as requiring reform; and in this sad country we are accused of all sorts of inconsistencies, and told at one time that religious strife is the cause of all our woes, and at another that political contention keeps us in perpetual broils—thus wasting our energies, and leading us to neglect our social improvement. I believe there is truth in both statements, and confess that I think almost every part of the public service in Ireland is marred in efficiency by party strife. Take a Board of Guardians—are not most of the appointments made from a purely political point of view. A schoolmaster, or master, or clerk to a workhouse is to be selected, and in nine cases out of ten the appointment is made from political bias, and not from the merits of the candidate; and so, also, with reference to the appointment of the medical officer under the Poor-law. Even here—where it is so important a proper choice should be made in the interests of the sick poor—the man goes in whose political sentiments are in unison with the majority. No matter how distinguished at college, no matter how intimate his knowledge of his profession—all this is nothing to them; but it is everything whether he goes with priest or Orangeman!

Every abuse, however, is *not* due to political and social causes. Sometimes in departments, where it is least to be expected, defects are found to exist, and remain unredressed (I think partly from oversight). I am certain it will be conceded that a manifest and grave defect exists in the last Act relating to lunatics in Ireland. It is there enacted that the medical officer of any dispensary district in Ireland shall go, examine, and certify before two magistrates as to the state of mind of any person supposed to be of unsound mind; and *thereupon* the deranged person (if a poor person) is to be removed in custody of the *police* to the Lunatic Asylum of the County, if the friends are unable or unwilling to do it. There is no provision as to the *mode* of transmission of the lunatic, and here is the great *defect*.

What is the effect as the law now stands? A pauper lunatic is brought before magistrates, probably in Petty Sessions—the medical officer attends, examines, and certifies; and there and then the constabulary have the custody of the patient, and forthwith are, as best they can, obliged to have him conveyed to the asylum. The police are utterly unsuited to such a duty. No one respects that force more than I do; but how can a couple of young constables know how to treat an afflicted lunatic or a violent maniac?

I have seen how! By binding the hands together, then the feet; then strapping the poor sufferers on the top of an outside car, if not quiet enough to walk, and then starting off a distance of twelve or twenty miles to the County Asylum!

Is this proper? Is this humane? And yet the constables do the best they can in fulfilling a painful and trying duty. This is no exaggeration. I have seen a poor lunatic female strapped on an open car in the manner I have described—poorly clad, and the rain falling in torrents, and hurried away in this miserable plight to the asylum. I think there is a remedy for this. Let each asylum in Ireland be provided with a "van," built expressly for removal of lunatic patients. Let two experienced attendants or asylum servants be sent out with this van for every certified lunatic to the residence of the patient, if the relatives cannot accompany the transmission, who, on receiving the medical certificate and the magistrates' order, are to be responsible for the safety and removal of the lunatic. This course would do away with all those disgusting exhibitions through the country districts, and along public roads which are now occasionally witnessed on the transmission of pauper lunatics—not only this, but it would avoid the cruel injuries sometimes unavoidably inflicted upon the wrists of the more violent. These experienced officials should be well chosen for this special work, and should go out provided with all the safe means of restraint, such as a straight-waistcoat, so that the poor afflicted maniac would be removed to hospital in a perfectly safe way.

"*The van*" should have no side windows, but should be lighted from *above*.

I have spoken to several medical gentlemen connected with asylums in Ireland, and they all agreed with me that the present mode of transmission of lunatics is very objectionable. It may, by some, be wondered that the Government Inspectors have not yet recommended a change in the law such as I have now proposed; but, I am satisfied their not having done so is explained by the probability that they have never been made aware of the exposures, indelicacies, and cruel hardships attending the present mode of removal of pauper lunatics. Now that Government will be supplied with large sums of money from the Church Act, and have intimated their intention to apply some part to the benefit of idiots and lunatics, I propose that each asylum in Ireland be supplied out of these or other funds with a covered van,* properly constructed and properly officered, to be used for the purposes mentioned in this letter.

I am yours, &c.,

WILLIAM WAUGH LEEPER, M.D.

Loughgall, Dec. 1870.

CAIRO AS A WINTER CLIMATE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mrs. Appleton, a lady whose name is now familiar to many of us, from the energy she has shown in carrying out her plans of assisting those suffering from chest diseases to winter in Cairo, has kindly sent me the following description of her location there, which may prove interesting to some of your readers:—

"New Hotel, Cairo,

"November 25th, 1870.

"I arrived here safely on the 16th, and found everything very satisfactory. The rooms large, well furnished, and fitted

* Hired horses are always to be had.

with grates; the table good, and the servants Europeans and attentive. The weather is like June in England; the roads are good, and well shaded with trees. We had a very comfortable journey hitherto, *viâ* Liverpool, for which we paid £16 16s. The rail from Alexandria to Cairo is £1 1s. Those with me are already much better, and seemed charmed with the result; and when we think of the winter you now, no doubt, have at home, it is a subject for thankfulness that invalids can find such winter quarters as these. The bath rooms are beautifully arranged, and everything is very clean—a great attraction in this country."

It seems to me that very few winter resorts could prove so agreeable to invalids as Cairo. I know Malaga and Spain well; but the climate of Cairo is far better in bronchitis than Spain is or France. In asthma and in incipient consumption, too, it is an excellent resort.

I am, &c.,

Charles R. Drysdale, M.D.,

Physician to North London Hospital for Consumption.

THE CONTAGIOUS DISEASES PREVENTION ACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Disclaiming any present intention of discussing the merits and demerits of the Contagious Diseases Prevention Act, I would request space in your columns for the consideration of some difficulties and objections which I think present themselves in carrying into effect the views and measures which some of the opponents of that Act propose as a substitute for it.

Desiring not only to get rid of this enactment, in their opinion so objectionable, but also hoping to strike at the root of an evil which continues to exist in defiance of all checks and remedies, religious, moral, or social, as at present administered; they propose to supplement if not to supersede them by two very comprehensive expedients: (1) Universal marriage, with limitation of the number of children to two; (2) Increased facilities for divorce.

The first of these must have its necessity and justification in the supposition that all, or at least the vast majority of, men are under the yoke of an imperative and inexorable law of incontinence, the behests of which they are unable to resist. If resistance be out of the question, an immediate or early satisfaction of sexual appetite in a *quasi* lawful, and regular manner, plainly affords the only escape from the evils of unregulated and unlawful incontinence. In order, however, adequately to suit the remedy to the necessities of the case, it is necessary that we should keep in view the period when that appetite awakes and becomes imperative. In many males (for I confine my remarks to my own sex) sexual passion, even without undue stimulation, discloses itself at 13 or 14 years of age; in a still greater number at 15 or 16; and in most healthy males it is in full activity at the age of 18. Between the ages of 18 and 24 or 25 it is generally more importunate than at any subsequent period, so that if it were possible for a man to contain till 25, he would be able fully to master the passion afterwards. Now, if the existence and predominance of sexual craving is to be the one determining condition and reason for marriage, all men should marry at 18 years of age, if not sooner, for discretion is then weak, and passion is strong. The advocates of marriage, so conditioned, may be ready and able to obviate the objections social, domestic, economic, and even moral to which it is obnoxious; but to me they appear insuperable.

It is true they propose to obviate one, and I think by no means the greatest of these objections, by limiting the number of children to two. Such a restriction, however, appears to me utterly inconsistent with the presumed necessity which has compelled the marriage. If it be true that under the existing relations between the sexes, the great majority of men and boys will rush into the unlawful gratification of sexual appetite, regardless of the checks interposed by religion, morals, prudence, and due regard for character and health, can we expect, when in condescension to such frailty, provision has been made for the lawful gratification of that appetite, that mere conjugal discretion will limit conjugal indulgence? I have a very high opinion indeed of the beneficial change in feelings and habits which well-assorted matrimony is capable of producing, but I do not expect it to work such a moral and physical miracle as this would imply, though rating a man's powers of self-restraint more highly than the advocates of universal marriage do.

We have, indeed, heard of certain unnatural precautions, which render conjugal indulgence consistent with the defeat of its natural results; but as I do not believe they have found advocates in the course of this discussion, I merely glance at and pass them by.

As the dreadful effects of prostitution, and of its attendant disease on our soldiers, have forcibly arrested and excited both official and public attention, the necessity of universal marriage for their safety, and the protection of the victims or partners of their vicious indulgence, has been more vehemently urged than on behalf of others. Instead of an army of celibates, we are to have an army of married men. Are we, then, to refuse to enlist bachelors? or are the functions of the minister of religion, or of the registrar, to be made necessary adjuncts to those of the recruiting sergeant? Where shall we find women who would worthily fulfil the duties of married life, and also be willing to cast in their lot with too many of those who can be induced to enlist?

But all other difficulties, and I might enumerate many more, fade into insignificance in comparison with those interposed by financial considerations. The constant society of the wife will, of course, be necessary for the incontinent soldier, if we are to obtain the benefits expected from his marriage and escape the evils of illicit intercourse. Deprived of that society for even a short time, he will have understood that self-restraint is not expected from him and therefore, self-indulgence is scarcely criminal. Whether on home or foreign service the wife must accompany her husband, or we may expect him to realize the picture drawn by the satirist—"Venerem incertam rapiens more ferarum." But will the nation be willing, if able, to meet the enormously increased expense of barrack and transport accommodation thus rendered necessary? One or ten thousand soldiers, with as many wives, and some hundreds or thousands of children, which may not be left behind, unless baby-farming be extensively adopted, necessarily under Government supervision, if we are to escape the horrors that would otherwise attend it. Again, what would be the fate of such a lumbering and unwieldy host under the exigencies and vicissitudes of active service? I think when the advocates of a married army take into calm consideration these and other obstacles to the adoption of their scheme, they will find them to be insurmountable.

The second ingredient in the panacea for the removal of prostitution is, in my opinion, greatly more objectionable than even the first. Facilities for divorce exist pretty extensively in other countries, with results of which we have heard and still hear; but amongst those results I have not noticed the abolition of regular professed prostitution.

It is, no doubt, an indulgence to human frailty, and in the opinion of those who believe we have to choose between universal incontinence and universal matrimony, contracted mainly at the dictates of appetite, it would no doubt be a necessary addendum to the latter, followed, as it surely would be, by frequent alienation and mutual disgust resulting from satiety, caprice, incompatibility of temper, and many other causes, any or all of which would, in consonance with the original reason for wedlock, require to be consulted and yielded to. I confess it brings to my memory the tinker's invitation to his doxy in Burn's "Jolly Beggars":—

> "This hour we meet, in rapture sweet,
> Wi' mutual love and a' that;
> But for how lang the flee may stang
> Let inclination law that."

If matrimony, restrained or restricted as to the number of children, may be called matrimonium strictum—matrimony, relaxed by increased facilities for divorce in compliance with "the law of inclination," may be called matrimonium laxum. I have already expressed my doubts whether it would lessen prostitution *eo nomine*, and as I feel sure neither the morals nor even the health of society would be benefited by the substitution of the one for the other, even were such substitution possible, I am equally sure society would not sanction the exchange.

I remain, Sir, your obedient servant,

John Elliott, A.M., M.B.

Waterford, Dec. 9, 1870.

Obituary.

FRANCIS TAYLOR, Esq., of Romsey, M.R.C.S., L.S.A.

Francis Taylor was born at Hull, on July 25th, 1811, and, at the age of nineteen, came to London to be apprenticed to a medical practitioner, and to finish his course of study by "walking" one of the hospitals. He attended University College and the Middlesex Hospital, where he distinguished himself highly, and obtained gold medals in the classes of Materia Medica and the Principles and Practice of Medicine. Having completed his studies, merely for recreation and a change of scene, he took the post of assistant to Mr. (afterwards Dr.) Beddome, of Romsey, Hampshire. Francis Taylor came out as a new light in Romsey; established a Scientific and Literary Society; was himself the centre of it, organised a course of instruction; delivered very valuable courses of lectures on chemistry and physics, illustrated by numerous experiments performed with his own admirable apparatus. He shortly married Miss Brounger, Mr. Beddome's step-daughter, and it was no doubt this event, in conjunction with his becoming Mr. Beddome's partner, which occasioned his stay in Romsey. He became a member of the Corporation, an Alderman, several times Mayor of the Borough, and was up to the time of his death one of the magistrates of the borough. In all town matters his advice was sought eagerly. He took a foremost part in restoring the Abbey Church, and completed the last step by fixing the cross. We may here observe that as an inventor, he first made india-rubber tubes for infants' feeding bottles, turned with his own hand a boxwood shield for a cracked and lacerated breast, and afterwards had this simple yet invaluable instrument made in glass, and fitted with the india-rubber tube. As a surgeon he was remarkably skilful, sympathetic, and successful. His manner at once inspired confidence, and he was always firm in resolutions and earnest in his undertakings. He was never so happy as when engaged in toiling for the well-being of his mankind, and, relieving poor suffering humanity. He died on Friday, Nov. 18th, the cause of death being heart-disease, and he was buried in Romsey cemetery on the 25th, a week after his decease. He worked to the last, and his great exertions in past years perhaps laid the foundation of the disease which terminated his mortal career. He lived and died a Christian without doubt or fear, and of him it may be fairly said, that he died as a good man should die "at his post."

Medical News.

The Modern Russian Soldiers must be a Jack-of-all trades if half the stories about him are true. Thus we learn that in Russia boots are issued in the piece, and made up by the soldier himself. The whole Russian army consists, therefore, of cobblers, and we believe that among them are to be found many excellent bootmakers. The idea of a Russian soldier employing a tradesman to make his boots is out of the question, as his small pay is scarcely sufficient to keep body and soul together. *Apropos* of this, we may mention that the commanding officer of a Russian battery of artillery receives about three-halfpence per day per man to provide all food, with the exception of flour and cabbages. The Russian soldier grows his own cabbages, and this excellent vegetable forms a large portion of his diet. His dinner consists of a thick soup, made of a little meat and quantities of cabbage and black bread. Many English soldiers know nothing of the miserable pay, diet, and equipment in foreign armies. A modern English soldier is, comparatively speaking, a millionaire. He is well paid and clothed, has not to make his own boots, and gets three good meals a day. The uniform of a Russian soldier does not belong to him until it has been in use for two years. When he goes on parade he must don his new clothes, which belong to the Government; but when off parade he must wear his two-year old clothes, which belong to himself. The Russian knapsack weighs about twenty-three pounds, and among other things contains a case of blacking for dying the moustache when in review order!—*Globe.*

Aid to the Sick and Wounded.—Several large cases of splints, bandages, field tourniquets, amputating and other instruments, supplies of chloroform, morphia, &c., with every modern appliance in medicine and surgery, have been recently dispatched to the head-quarters of the force under the orders of General Garibaldi. The cost was defrayed through the impartial humanity of the National Aid Society. The stores &c., were selected under the personal supervision of Dr. H. Scott, Professor Partridge, and Mr. Henry Spicer, and are being conveyed by the instrumentality of the latter gentleman to the scene where there is urgent need of such alleviations to human suffering. A large box of hospital clothing, linen, &c., was added by the kindness of Mrs. Chambers.

Pauperism.—The army of London paupers seems at length to be diminishing when season is compared with season. A slight turn for the better commenced nine or ten weeks ago, and the divergence between this autumn and the last became more marked with the advance of the quarter. On the first week of October there was a decrease of one per cent. as compared with the corresponding week of 1869; on the first week of the present month the decrease had risen to five per cent. We may feel the greater hope of the continuance of this satisfactory change, because the following figures, which are abstracted from Mr. Goschen's weekly tables, show that it has been steadily progressive hitherto:—

Number of Indoor and Outdoor Paupers (exclusive of lunatics in asylums and vagrants) relieved in the metropolis during the ten weeks ended with the first week of December, 1869 and 1870, respectively.

	1869.	1870.	Decrease in 1870.
First Week, Oct. - - -	128,880	127,673	1,207
Second ,, ,, - - -	127,533	127,036	2,497
Third ,, ,, - - -	131,186	129,806	1,380
Fourth ,, ,, - - -	133,711	131,200	2,511
Fifth ,, ,, - - -	136,182	132,537	2,645
First Week, Nov. - - -	138,236	133,751	4,485
Second ,, ,, - - -	139,928	135,251	4,677
Third ,, ,, - - -	142,436	137,413	5,023
Fourth ,, ,, - - -	144,788	138,470	6,318
First Week, Dec. - - -	147,467	139,969	7,498

Whether the decline may be due to a greater demand for labour than in 1869, or to a more wholesome administration of relief by the guardians, there is nothing before us to prove. Probably both factors have been combined in the production of the result. The change, cheerful though it be, nevertheless leaves about one in twenty of the metropolitan population on the pauper relief lists, if the vagrants and lunatics in asylums are counted in.—*Pall Mall Gazette.*

Contagious Diseases.—The Contagious Diseases Acts Commission met on Wednesday and Thursday, at 13 Great George street. The Commissioners present in the course of the two days were—The Right Hon. W. N. Massey (Chairman), the Right Hon. Viscount Hardinge, Right Hon. Sir J. S. Pakington, Bart., M.P., Right Hon. Lieut. General Peel, Sir J. S. Trelawney, Bart., M.P., Vice Admiral R. Collinson, Charles Buxton, Esq., M.P., A. J. Mundella, Esq., M.P., Peter Rylands, Esq., M.P., the Rev. Canon Gregory, the Rev. J. F. D. Maurice, the Rev. J. Hannah, J. H. Bridges, Esq., M.D., G. E. Paget, Esq., M. D., Holmes Coote, Esq., F.R.C.S., G. Campbell, Esq., G. W. Hastings, Esq., Mr. R. Applegarth, and J. Anstey, secretary.

Gleanings.

On the Air in Workshops.

The *Bowdoin Scientific Review* contains an article from Dr. Sigerson, in which he says of the air of iron works:

Although a quantity of this iron, carbon and ash must daily pass in and out of the lungs, and besides, although a certain percentage must remain in them (as shown by Pouchet's dissections and Professor Tyndall's experiments), it is difficult to find a healthier body of men than those who work in such factories, Dr. Sigerson observed one exception, a young man whose lungs were weak, and who had suffered from blood spit-

ting, with cough, contracted in an American foundry, where the heat was excessive. He inquired whether the atmosphere heavy with dust did not affect him injuriously. The artisan replied in the negative ; he said that he found himself well in it, his cough came on at home on rising and lying down. These facts seem to indicate that the carbon poured into the air of cities from gaslights and fires may not have so injurious an effect as sometimes fancied.

In the air of a shirt factory, fine threads and fragments of cotton and linen were found, with a few ova which were translucent. In this factory the girls had become snuff-takers.

In the air of an oatmeal mill, fibres were seen present in unexpected numbers, together with minute fragments of the hull, and a few starch granules. Some spores and acari were detected. Near a threshing mill some smut balls were found in the air.

The air of flax mills was found to be especially deleterious. Fine particles of the flax, together with pointed particles of the hard bristly wood tissue, so that direct injury was done to the lungs by these, and concretions formed by the filaments. The mill people were great sufferers.

The air of printing offices contains minute particles of metal, particularly antimony. Dust taken from a rafter eleven feet above the floor of a printing office was analyzed by Professor Sullivan, and found to contain antimony but no lead.

The air of a hair-dressing room contained scales and minute hairs. In rooms where the machine brush is used, the amount is increased.

The air of the dissecting room contained fragments and fibres with the mark of the dissecting knife upon them! They were fibrils of muscles, yellow and white fibrous tissue, some cells, scales and corpuscles. The air of stables was found to contain moth scales, a few spores, hairs and fragments tinged blood-red.

Tobacco smoke, examined by the microscope, was seen to hold little globules of nicotine twirling and flitting about in it. The statement is made by Dr. S. that "some remained on the walls of the mouth ; when the smoke is breathed (by novices) more globules are retained in the lungs, and nausea and illness supervene. These globules, if found in the air distributed by a tobacco smoker, might be taken for germs."

The air of the rooms of "tea-tasters" was examined, but no report is given. An interesting observation, however, in regard to the avocation of the tea-taster will be quite new to our readers. The tea-taster has to take a sip with a quick inhalation, and thus a small shower of fine tea-drops enters the lungs. On examination of such tea-drops, a considerable quantity of tissue from the leaves was found, which might aid to tease the lungs. But the real agents of mischief were numerous little drops of essential oil, very plentiful in Assam tea, which was particularly severe on the tea-tasters. Nausea, derangements (or as Dr. S. says, dis-arrangements) of the nerves and sometimes syncope afflicted them.

Cyanide of Potassium in Pulmonary Affections.

Dr. G. Mazza ("Ann. Univers.," p. 592, 1869) has found the cyanide preferable to hydrocyanic acid on account of the great volatility of the acid, and its consequent variability in strength. He describes it as a sovereign remedy in many forms of lung disease, but especially valuable in tuberculosis. In order to combat the sleeplessness due to the harassing cough, he combines the cyanide with small doses of morphia. In the early stages of the disease, he has frequently seen complete recovery, and when more advanced a mitigation of the symptoms is apparent.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

Dr. L. Wangford.—We regret we cannot insert the letter of our esteemed correspondent. The subject was closed some few weeks since, and space forbids us to re-open a question that has been already so well and ably discussed.

BOARDS OF GUARDIANS.

Since our last issue, we have been favoured with an official letter from Mr. Knott, clerk to the Board of Guardians for the Worcester Union, in accordance with a resolution passed at a recent meeting, demanding the name and address of the writer of the article which appeared in our columns on November 30th. Of course, we decline to accede to such a request. Our remarks were written without prejudice upon the proceedings reported in the local papers, and we most certainly decline to furnish such information or withdraw anything however unpalatable, which, upon a careful review, was simply the truth,

VACANCIES.

Clonmel District Lunatic Asylum.—Assistant-Physician. Salary £100 per annum, with board and residence. (See Advt.)
King's College, London.—Assistant Demonstrator of Chemistry.
Charing Cross Hospital.—Assistant-Physician and Assistant-Surgeon.
Middlesex Hospital.—Medical Registrar and Superintendent of Post-Mortems. Salary £50.
Queen Charlotte's Lying-in-Hospital, London.—Medical Officer.
Marylebone Dispensary.—Resident Dispenser. Salary £85 per annum.
Clayton Hospital.—House-Surgeon. Salary £99 10s., with residence.
University of Durham.—Medical Tutor. Salary £120 per annum.
Alderbury Union.—Medical Officer. Salary £80, with fees extra.
Newcastle-on-Tyne Lunatic Asylum.—Medical Superintendent. Salary £250, with board.
Delting and Northmavine, Shetland,—Medical Officer for the two parishes. Salary £54, exclusive of private practice. (See Advt.)

APPOINTMENTS.

Baker, Dr., Physician to the General Dispensary, Marylebone.
Baker, Mr. H. F., House-Physician at St. Bartholomew's Hospital.
Branson, H. J., M.D., Resident House-Surgeon at the Doncaster General Infirmary.
Buchanan, G., M.D., Professor of Anatomy in Anderson's University, has been elected Consulting Surgeon to the Glasgow Maternity Hospital.
Drake, Mr. A. J., House-Surgeon to St. Thomas's Hospital.
Fausset, H. J., M.B., a Medical Officer to the Poplar Union.
Franklin, Mr. G. C., a House-Surgeon to St. Thomas's Hospital.
Hewetson, Mr. R., Assistant-Surgeon to the York County Hospital.
Hind, H., M.R.C.S., House-Physician to St. Bartholomew's Hospital.
Hornby, G., M.R.C.S., a Surgeon to the York County Hospital.
James, Prosser, M.D., M.R.C.P., to be third Physician to the Hospital for Diseases of the Throat.
Jones, C. S., M.R.C.S., Surgeon to the West Sussex General Infirmary.
Lyne, H., L.R.C.P., Resident Surgeon to the Farringdon Dispensary.
Mackenzie, Morell, M.D.Lond., M.R.C.P., to be Senior Physician to the Hospital for Diseases of the Throat.
Moore, J. W., M.B., C.M., L.K.Q.C.P.I., Physician to the Molyneux Asylum for Blind Females, Dublin.
Osborn, Mr. S., Resident Accoucheur at St. Thomas's Hospital.
Ravenhill, E. B., M.R.C.S., Resident Obstetric Assistant at the Queen's Hospital, Birmingham.
Semple, R. H., M.D., M.R.C.P., to be second Physician to the Hospital for Diseases of the Throat.
Symons, Mr. H. E., Surgical Registrar at St. Bartholomew's Hospital.
Tannahill, R. D , M.D., Accoucheur to the Glasgow Maternity Hospital.
Thompson, J., M.B., L.K.Q.C.P.I., Surgeon to the Police, Leamington.
Tosswill, Mr. L., a House-Physician at St. Bartholomew's Hospital.
Wilson, J. G., M.D., Professor of Midwifery in Anderson's University, elected Physician-Accoucheur to the Glasgow Maternity Hospital.

Birth.

Kean.—On the 11th inst., at Newry, the wife of H. I. Kean, M.D., Q.U.I., of a son.

Marriages.

Lynch—Oliver.—On the 10th inst., at St. Philip's Kensington, J. Roche Lynch, L.R.C.P., only son of the late J. Roche Lynch, M.D., to Marian, eldest daughter of J. Oliver, Esq., of the Inner Temple.
Martland—Waddington.—On the 15th inst., at St. John's Church, Blackburn, by the Rev. J. Baker, vicar, William Martland, M.R.C.S., Blackburn, to Margaret Elizabeth Yates, Blackburn, only daughter of William Waddington, Esq , Bank Cottage, Burnley, Lancashire.
Stawman—Mansie.—On the 13th inst., at the Parish Church, Silkstone, Wm. Stawman, Surgeon, of Barnsley, to Sarah, second daughter of the late Rev. A. Mansie, Missionary in Jamaica.

Deaths.

Dawson.—On the 7th inst., at Great Bromley, John Dawson, L.R.C.P.Ed., formerly of Great Bentley, aged 84.
Farrants.—On the 10th inst., at 241 City road, London, R. J. Farrants. Esq., F.R.C.S., aged 60,
Hogg.—On the 11th inst., at 1 Guildford street, Russell square, Mary Margaret, wife of Dr. Reginald Hogg, aged 52.
Jeaffreson.—On the 13th inst., J. F. Jeaffreson, F.R.C.S.E., of Canonbury lane, aged 61.
Kelly.—On the 29th ult., at Jarrow, Durham, James Kelly, L.R.C.P.Ed., M.R.C.S.E., aged 42.
Lawrence.—On the 14th inst., at South street, Thurlow square, Richard Moore Lawrence, M.D., M.R.C.P., aged 48.
Morison.—On the 8th inst., at Wellfield House, Wingate, Co. Durham, Alex. C. Rutherford, third son of John Morison, M.D.
Morris.—On the 7th inst., D. P. Morris, M.R.C.S.E., of Colchester, aged 46,

Inaugural Address

DELIVERED AT THE

OPENING OF THE SESSION, 1870-71,

OF THE

SURGICAL SOCIETY OF IRELAND.*

By Albert J. Walsh, L.R.C.P. Lond., F.R.C.S.I.

Gentlemen,—As President of the Royal College of Surgeons it becomes my duty, and, indeed, I feel it to be the high privilege of my office, to preside at this the Fortieth Opening Meeting of the Surgical Society of Ireland, a society than which no other has done more to advance the knowledge of disease, to improve the treatment of it, and to raise the art and science of surgery in this country, to its present proud position. Gentlemen, when I look over the long list of worthies, men of the highest attainments, mental cultivation, and practical skill, who have filled with credit to themselves, and incalculable benefit to the science of surgery, the chair which I now have the great honour to occupy, and to which I have been raised by the kindness and good feelings of my professional brethren, I confess, I feel most anxious, lest during my official year our Society should not continue to hold that high character and European reputation, which the importance of its debates and the practical usefulness of its papers have heretofore procured for it; but though I do feel anxious, still I have every confidence that the industry, talents, and zeal of our present members will enable me at the expiration of my presidency, when resigning my trust to my highly esteemed and able successor, to do so with feelings of pride and gratification, arising from the progress we shall have made. The time has long passed by since surgery was considered but a trade, when a good surgeon meant a little more than a clever craftsman, only to be called on to act as operator, under the directions of the physician who then assumed a higher grade and a superior education; but even up to the period when such societies as ours were founded, surgery was at a very low standard, and it was not till it began to be treated as a science, that it quickly made the progress and assumed the importance which renders it so remarkable at the present day; how great the change, how improved the position, social and intellectual, of the educated surgeon. To societies, such as ours, much, if not all, this improvement is mainly due. For during the last century and commencement of the present, the great men who from time to time made valuable discoveries and gave a life-long labour to the advancement of surgery, were comparatively limited in their sphere of usefulness, their writings were read by few, their examples were disregarded, and it was not until Louis Chopart and others, at the Academy of Surgery in Paris, and Dupuytren, Bichat, and Boyier, at the meetings of the Ecole de Médecine, by reading their treatises, and submitting them to a public discussion in these societies, that the rapid and wonderful progress in the science of surgery took place. In London the Medical and Chirurgical Society carried on the good work, and deserves the gratitude of the Profession. In that Society Pott, Cooper, Brodie, Laurence, &c., read their treatises, gave their experience, and contributed largely to the advancement of our knowledge; and in this country our own society has not been less active in its usefulness. Its meetings, presided over by Crampton, Colles, Kirby, Cusack, Bellingham, and many others, have had the greatest influence in giving life and energy to the study and cultivation of surgery; and the intercourse continually maintained by these societies amongst the members of our profession, must be followed by what I consider as only second to its rapid progress, namely, that maintenance of friendly and generous feeling by which all those sentiments of distrust, jealousy, and petty rivalry are altogether eliminated and superseded. For these reasons I am convinced that a society such as ours

* Delivered before the Surgical Society of Ireland.

must tend, in no small degree, to the comfort and happiness of the individuals of whom it is composed; for whilst there is nothing more painful, to a well constituted mind, to be at variance with, or suspicious of others, so is there nothing which tends more to elevate the moral character, or to inspire peaceful and contented feelings, than the consciousness that our competitors are friends with whom we are on such a footing that we mutually make allowance for each other's failings, and are on all occasions ready to do justice to each other's good qualities, whether of the head or heart. Gentlemen, there are in this city several societies whose objects are similar, if not identical, with our own; some founded more than half a century ago, when physicians, surgeons, and obstetricians were looked upon as distinct bodies, each having their own peculiar studies, laws, and pursuits. This was, at first, necessary, and perhaps unavoidable; but now that science and the progress of the age, have overstepped the boundary lines laid down by the original founders of these societies; and as the subjects discussed, night after night, at their meetings partake as much of the medical as surgical character, it has forced itself on my mind that the time was approaching, if it had not already arrived, when their usefulness would be greatly increased, knowledge would be advanced, and science benefited by an amalgamation of the governing bodies. I have been led to this conclusion when I consider the objects and nature of these societies, which have been founded for the advancement of medical and surgical science, by reading and discussing papers relating thereto, but were never intended to be, and I trust may never become, arenas for the display of scholastic ingenuity and argument in support of this or that peculiar school or theory. Still less did their founders intend that they should be places for the exhibition of great eloquence or powers of debate. The opportunities for cultivating which talents, no doubt estimable and most useful acquirements, are to be found in other societies. In the medical societies, men of all degrees of standing in the Profession can bring forward for discussion the fruits of their experience or matured knowledge, and the results of their industry and research, in order that after being added to by what others can contribute on the same subject, and tested by discussion, the real value may be ascertained. Again, it not unfrequently happens that one of the younger and more inexperienced members of the Profession, having noticed what appeared to him an important peculiarity or appearance in a case or specimen which has presented itself, as he supposed for the first time to his vigorous and active mind, submits a paper on the subject to the Society, and in the debate arising thereon, it may turn out, from the observations of others, older and more experienced than himself, that, that which appeared to him to be new had already been observed and noticed by others, or that his deductions from the facts themselves, and explanation of the appearances, were not correct, or such as experience warranted. All such papers are published in the "Proceedings" of the different societies, and thus, too frequently, hasty and ill-digested matter, by no means for the credit of the societies, is given forth to the public, notwithstanding the existence of Publication Committees. Now, an amalgamation of the governing bodies of the societies, not of the societies themselves, would, I believe, greatly tend to remedy this evil; and to carry out this I would suggest that a Board of Examiners be selected from, and elected by, the several councils of the societies, to which Board all papers, after having been discussed by their own bodies, should be submitted prior to publication, and then, after being examined by the amalgamated board, and after, if found necessary, a further discussion upon the subject, it was considered worthy of publication, the paper would go forth to the Profession and the public with the value and support of the Board's sanction. But as this is not the time or place for discussing this matter, I only throw out these suggestions as I intend, after having further digested the details of my plan, to bring it before the Council of our Society, which is the proper place for its consideration. Gentlemen, it is now my painful duty to notice the great loss the Society has sustained during the past year by the lamented death of Professor Geoghegan. I am certain no person whom I now address can but recollect the valuable papers he submitted to the Society, and the pleasure they derived from the clear and lucid manner in which he conveyed his ideas, and treated the subjects therein—his language so concise and so completely to the point, conveying much information in few words. I confess it was always to me a pleasure to listen to him, and the value of the information given by him in this clear and easy-to-be-understood style was incalculable; he has, indeed, been a loss to our Society, which, I fear, we cannot easily replace, and the Profession will long feel the blank occasioned by his death. There is but one other subject to which I would beg to call your attention before I close my address, that is, to the rules and regulations which govern this Society. During the past year your Council have given much attention to these rules, and, after anxious and careful consideration, resolved upon referring the matter to a sub-committee, consisting of your honorary secretaries, Dr. Benson, who for the past thirty years and upwards has been identified with, and devoted to, the best interests of our Society, and to whom we owe so much of its great success, and Mr. B. Wills Richardson, whose anxiety about, and attention to, its interests, cannot be surpassed, in conjunction with the following members of the Council—Messrs. William Jameson, Christopher Fleming, and Humphrey Minchin, who have at all times identified themselves with the progress of the Society. These gentlemen, after much thought and consideration, framed a revised code of bye-laws, which your Council have adopted, and which they have submitted to the Council of the Royal College of Surgeons, who, no doubt, will approve of them. I would now venture to beg as a favour, that the members of the Society would support me during my period of office, and enable me to carry out these revised rules, especially those with reference to our debates, and, if this be done, I make no doubt, at the termination of my year of office, I shall be enabled to resign my charge into the hands of the Society with satisfaction to myself, and with the happy feeling that the good fellowship which should at all times pervade our intercourse with each other in our debates has never been marred or interrupted.

Original Communications.

HYDRATE OF CHLORAL.—ITS POSITION IN MEDICINE.

By Robert Uniacke Ronayne, L.R.C.S.I., &c.,
Youghal Infirmary.

(*Continued from page* 498.)

An admirable advantage, incidental to the employment of chloral, is the non-suppression or retardation of natural secretions, the bowels, skin, and kidneys continue to perform their normal functions unaffected by it to any injurious degree. The only unpleasant effect produced on the healthy, alimentary system is the occasional slight dryness of the fauces at morning, which, however, a drink speedily removes, and in respect to the secretion of the kidneys, where we also find a slight deviation from this rule. Here, however, the disturbance seems equally trifling. The urine passed immediately after a chloral sleep reacts neutral and does not reduce the copper of Fehling's solution; but that voided some hours later is more dense and does reduce the copper of Fehling's solution, thus similating a temporary glucosuria; in other respects it is normal. I have never seen constipation

caused by even its lengthened administration. On this subject, Dr. A. M. Adams speaks with confidence—"In head affections, where there is torpidity of the bowels and retention of urine, chloral does not, like opium, encourage this state of matters, but would seem, owing to some reflex action, whilst effectually overpowering undue nervous disturbance, to stimulate or assist the bladder and bowels to a more healthy action." This avoidance of any inclination to check the eliminative processes, causes chloral to be especially valuable in fevers where retrocession of these is sure to be attended by serious consequences. The administration of chloral is not followed by morning headache, nausea, nor disinclination to receive food. This sick headache is one of the most annoying followers of opium, and its absence from the track of chloral is an inestimable benefit; yet, further, I have seen some cases in which similar affections (though not arising from any drug have been effectually removed by its exhibition), returning on its remission, and again departing on its restoration. So far from giving rise to intolerance of food, the patient awakes bright, comfortable, and refreshed; free from lethargy of mind or body, and having generally a better desire for breakfast than previously felt. This appetite is a curious result of the use of chloral, and I have so often observed it, and noticed the patients themselves comment on it, that I cannot help associating it as a special attendant on chloral action. The craving for the morning meal which it produces cannot be accounted for by the good night's rest and the absence of pain alone, and I have been particularly struck with the numbers long deprived by cachexia of a taste for food, who voluntarily rejoiced in their newly acquired relish for breakfast. Action of the skin, so far as I have observed, seems little changed by it, if anything, I fancy it lessens the sweating of phthisis, by quieting the general excitement, and causing contraction of the capillaries. These appear to me the ordinary phenomena which accompany and follow the presence of chloral, but it is also capable of developing well marked particular effects. Amongst the most advantageous of these seem to be the decided control it exercises over the irritable cough of bronchitis and phthisis. In many of these cases, opium is highly objectionable; conium useful, but uncertain; and hydrocyanic acid often next to worthless, unless given in dangerous doses. Here, chloral quickly gives rest, and renders the harassing cough less frequent and harsh. Dr. Taylor, writing to Sir James Simpson of its benefit, in a case of congestive bronchitis with hæmoptysis, says—"As I contrast the distressed and audible breathing of last night with the tranquil sleep and improved state of the patient to-day, I cannot help concluding that, chloral has a *directly sedative effect on the whole respiratory surfaces.*"

Besides this, I have noticed other and important therapeutic actions result from its use, not the least useful of which, is its power of diminishing the quantity and improving the quality of the sputa in the above-mentioned chest diseases; in such cases it not only controls the severity and lessens the hardness and frequency of the cough, but it also reduces the actual amount of expectoration in a remarkable degree, sometimes cutting it down by one-half or more in a single night. In every case of this kind, I have achieved a similar result; this I consider a most valuable power, as by it a world of restless, exhausting misery is spared the already over-taxed weakness of the invalid, and life is prolonged by the husbanding of such slight vital resources as he yet possesses. In asthma, the ability of chloral to avert and arrest spasm borders on the wonderful. In severe cases where the nocturnal paroxysms were excessive, keeping the wretched sufferer sitting up in bed gasping for breath, a timely dose taken on the approach of dyspnœa, has invariably warded off the attack, or, if it had already set in, relieved the spasm, permitted the recumbent posture to be resumed, and procured a quiet night's rest. Those to whom I have given it have derived more benefit from its use than from stramonium, ethereal tincture of lobelia, or other antispasmodics, especially favoured in such cases; it has been spoken highly of in pertussis, but on this point I cannot treat with experience. Dr. A. M. Adams, however, thinks highly of its value, and writes—"Where the cough is unusually severe, and likely in consequence to lead to other complications, it will prove a most valuable remedy—about six grains given only at bed time will in most cases ensure a comparatively quiet night." Perhaps, the most peculiar result which I have undoubtedly obtained from chloral administration, although I am at a loss to account for it physiologically, is its efficiency in arresting the disastrous colliquative diarrhœa of phthisis. Although, as I before observed, its habitual use does not tend to the production of constipation, yet I have several times by its administration stayed the vital torrent where mist. cretæ c. opio, vegetable astringents and sulphuric acid with opium had hopelessly failed. Of course, there are limits to such action, and I should have little faith in its good offices where ulceration had actually taken place, but, in the stage of tubercular irritations which precedes the breaking down of the mesenteric deposits, I have experienced decided success by its aid alone. Chloral may be used with benefit in many forms of irritable stomach. It almost always calms that excitable organ, and even holds somewhat in check the obstinate vomiting of organic disease. I have been able by its means to procure many hours' rest, and tolerance of food for an ulcerated stomach, and I know of no other preparation for which I could say as much. It is possible that it might prove equally useful in the obstinate vomiting of pregnancy, and even become a respectable adjunct to the marine surgeons' nostrums against sea sickness. In various forms of irritability of the heart, as well as in valvular diseases of that organ, I have used chloral with satisfactory results. Although M. Bouchut says, "it increases arterial tension," I have found it relieve fluttering, and by checking the disposition to irritability, allay irregular action. In valvular disease, it appears also to do good by steadying the organ down to its work, and thus relieving laboured over action. Sir James Simpson has called attention to one most valuable property of chloral, viz.—that of lessening the pains of labour without restraining contractions of the uterus. He observes—"I have found the parturient uterus to go on contracting regularly and strongly when the patient was so deeply asleep under chloral, as to be only very imperfectly awakened up with the expulsive efforts of labour." Here, then, we find a much more convenient and safer companion in the lying-in chamber than chloroform, which latter can hardly be properly administered without the aid of a second medical attendant, a thing seldom attainable even in respectable private practice, and completely beyond the reach of the ordinary dispensary physician.

There is one disease of formidable aspect, about which, in connection with chloral, some controversy has arisen, I allude to the Sphynx of Medicine—traumatic tetanus. There are some very important cases of recovery on record where this agent has been credited with the cure; and that of M. Verneuil, in the *Lancet*, April 16th, 1870, seems the most convincing. On the other hand we have statements equally reliable, charging it with complete inutility to meet such straits; but as one swallow does not make a summer, neither can one or two cases for or against establish a rule. The truth may lie on both sides. All forms of tetanus are as surely not to be cured by any one drug, or combination of drugs, as that no hand could raise a Tower of Babel. Whilst on the other side many of the failures may have fallen unjustly on the shoulders of chloral, as all practitioners meet occasionally with cases of constitutional idiosyncracies, where susceptibility to the action of some particular medicine is found wanting; and it is possible that amongst the unsuccessful ones such may be found. I have met but one peculiar case of this nature, where a man suffering from chronic rheumatic arthritis, took large quantities of

chloral without its producing the smallest effect; whilst a patient in the next bed to him spent his nights in a pleasant oblivion derived from one-sixth the dose. I fancy the former's insusceptibility arose from a hyperacidity of the system to which his disease made him liable. But should more extended trial prove chloral to have no power over tetanus, I still think that should not make us undervalue what it has actually done in the broad fields of medicine and surgery. Amongst the other ailments in which chloral has found favour, I may mention hysteralgia, dysmenorrhœa, hysteria, pleurodynia, gastralgia, and cancer. In irritable bladder and chronic cystitis, Sir James Simpson has seen "it give the patient much longer and more perfect rest than large doses of opium." Liebreich speaks well of its utility in rheumatism, convulsive coughs, acute mania, *delirium tremens*, and as a sedative after surgical operations; and Bouchut considers it the most prompt and efficacious remedy in intense chorea, where the life of the patient is threatened. It is as well to mention that I have seldom found it necessary to prescribe chloral in higher doses than from fifteen to forty grains, and that it is neither an accumulative medicine nor one which must necessarily be increased in quantity on repetition — the same amount which relieved pain, or produced a soporific action, this day month does the same to-day. Now, as to its toxic effects, it seems that the functions acted on by chloral are attacked in this order:—1. The cerebral; 2. The voluntary muscular; 3. The respiratory; 4. The heart; and it is only when given in doses sufficiently large to induce a depressing effect on the last, that any threatening or fatal result is to be feared; and since the ultimate action of chloral and chloroform are similar, only that of the former is infinitesimally slower than that of the latter, it follows that poisoning by chloral must be more than proportionately rare.

Dr. Russell Reynolds gives the history of one nearly fatal case, but I find no record of actual death which can be laid at its door. The Paris Correspondent of the Medical Press and Circular (March 9th, 1870,) states that, "M. Laborde took progressive doses of a gramme, a gramme and a-half, and two grammes, on three successive days, and he suffered such painful sensations in the epigastrium, with nausea, cholic, and profuse sweats, that he was obliged to desist." The same writer cites a case of his own, "in which the patient preferred to endure intense neuralgia of the face, rather than experience the sensation left by a medium dose after it had completely banished the pain and procured several hours sleep. The feeling of illness all over was so distressing all the next day that another dose was altogether refused." I cannot regard these cases as proving anything more than that like all other medicines, chloral sometimes meets with constitutional disabilities which preclude its use, but that these must be rare indeed, I judge from the fact that in all the cases in which I have given it, but one such peculiar physical temperament has been met, and in no one has any of the disturbances mentioned been produced. Sir James Simpson states—"I have exhibited chloral in continuous small doses for one, two, or more weeks in succession, and apparently with most marked benefit." Now, when we know that his ordinary dose of the drug was sixty grains, we may presume that by small doses he meant about thirty, and that in his large experience he records (as far as I am aware) no such evil effects, I think amply justify me in coming to the above conclusion.

M. Liebreich has pointed out that strychnia is the best antidote to chloral poisoning, but from its insolubility in sulphuric acid, I think the latter is likely to be of service should such a case arise.

Having thus endeavoured to illustrate the various uses to which chloral may be applied, it only now remains for me to express the conviction which a lengthened and impartial, even jealous, trial of chloral has forced upon me, namely—that it is by far the surest, safest, most efficacious, and least objectionable hypnotic which we possess; that it is far superior to opium in all the qualities which they hold in common, and in the absence of all the ill effects which the latter is capable of exercising, and that with the exception of such cases as rupture of the uterus, peritonitis, and such like, where opium's very vices are its best commendation, it is capable of completely supplanting that drug.

ON DISEASES OF THE SKIN.

By J. L. Milton,

Surgeon to St. John's Hospital for Skin Diseases.

(*Continued.*)

The Pathology of Eczema.—1. The first of these circumstances is, that when the discharge comes from a part furnished with hair—as the leg, for instance, minute accumulations of fluid form at the junction of the hair with the skin. These are possibly considered as vesicles. M. Devergie, for instance, seems to take this view, but on more close scrutiny, it will be found that neither their course, situation, nor form correspond with those of a true vesicle, and on touching one of them gently with a blunt-pointed glass rod, a minute drop of serum will be found adhering to it. I have always failed to detect the slightest trace of cuticle on these little drops of fluid, whereas we know that the covering of vesicles will resist some force. When M. Devergie speaks of the fleeting nature of the vesicles of eczema, he overlooks the fact that genuine vesicles are not very fleeting, even in such transient disorders as miliaria, and that those of herpes, with which eczema, if vesicular, must be classed, not only bear such distension as to become globules without bursting, but endure the friction of the clothes for days without rupture. Herpes may appear again and again on the same person, without a single patch becoming eczematous. Eczema, so far as I have been able to observe, never becomes herpetic, nor have I ever seen an outbreak of vesicles on a patch of eczema. At times, portions of skin are seen covered with ill-developed vesicles, looking as if they would become eczematous. I have never observed them do so, but I do not impugn the accuracy of those who say they have. They sometimes complicate or accompany genuine eczema, but if the latter complaint continue ever so long, or reappear ever so often, they do not make their appearance again. *And these facts are, I submit, strong grounds for believing that there is a radical and unalterable difference between eczema and herpes—the vesicle and the papule.*

2. The second circumstance is that in the vicinity of eczematous eruptions, vesicles and bullæ are occasionally found, the former not unfrequently appear about the knuckles and on the back of the hand. These vesicles, however, last but a very short time, and in most of the cases I have seen they did not return after being once removed; in a few instances they did. No relation seemed to exist between the number of attacks of this kind of complication and of the outbreaks of eczema. One patient who had had eczema breaking out for years had never suffered from vesicles. In another case I was informed that each eruption of eczema had been complicated in this way and so on. So far, however, as my own observation goes, I never saw it more than twice in the same patient. This eruption seems to be in no way dependent on the state of the eczema, it will disappear when the latter complaint is stationary or getting worse. In all the cases I ever saw the vesicles were rare in proportion to the numbers and extent of the eczematous patches. A patient might have thirty or forty of these, and yet only one near which there were vesicles. These vesicles always healed quickly and did not become eczematous, nor was the disease in their immediate neighbourhood influenced either by their outbreak or departure, sometimes appearing afterwards in its usual form on the very spot where the vesicular eruption had been; a still stronger proof, it

appears to me, than even any of the foregoing, that there is *a wide distinction between the vesicular and eczematous inflammations.*

3. The third reason is, that a disorder which seems to me to be a form of herpes, has been confounded with acute eczema. It begins with heat, severe itching, and pungent, stinging pains. Vivid red patches form, and serum is effused under the cuticle, which is raised up in firm, irregular vesicles; then the serum becomes of a whitish hue and grows turbid, the vesicles break, the fluid oozes out, the cuticle is thrown off, leaving the skin red and tender, and the disease passes away, mostly, I believe, to return no more. In still more severe cases, numbers of little pustules form around the vesicles, constituting really an impetiginoid herpes. Now, this complaint, seen when the cuticle has just given way, and when the serum is pouring out freely, might be taken for eczema; but except that the vesicles run into a mass, instead of remaining separate, I see nothing to distinguish it from herpes zoster. It never tends to take on the one essential character of eczema, that of discharging serum for an indefinite period of time. It disappears almost, if not quite, as fast when nothing is done, as when it is actively treated, and the vesicles are firm, and only break after the fluid has become turbid and flaky. At the end of two months' duration of this disease in a chronic form, I have seen some of the vesicles still full of fluid; how long they had lasted, it was, of course, impossible to say, as I am speaking of the time the disease had endured when the patient first came under my care; and the accounts given by patients or their friends of any particular vesicle to which, perhaps, their attention has never been directed, were not likely to be very connected or reliable. Still, there was every reason to believe that vesicles had existed for two months, and the very fact of their continuing to exist under any circumstances proves, that the tendency to form vesicles predominates in these cases, and this we certainly do not find in eczema.

On every ground of analogy as to anatomical and pathological features, course and cause, eczema solare, eczema mercuriale, vesicular eruptions on the hands in bakers, confectioners, &c., and vesicular scabies ought, I think, to be referred to the variety spoken of in the last paragraph, and the whole group classed with herpes, of which they are only forms. They are simply instances of blistering produced by heat, or some other irritant, and no more eczema than blistering with cantharides, or boiling water would be.* There is, I may here remark, one form of solar eczema, which might be mistaken for the genuine complaint. It is that affection in which a large portion of skin in an exposed part, as the back of the neck, is steadily invaded by a crop of vesicles which gradually turn flaky and yellow. It is very slow, and will last a long time. I have seen cases in which it had not altered materially during two months. It is not always due to extreme heat. In children, during cold, dry, east winds, the vicinity of eczematous patches will sometimes be invaded by vesicles in considerable numbers. For the most part these may be referred to the same variety. Eczema mercuriale I have never seen in the acute stage, but I think, from the descriptions given, that it clearly belongs to this group, and that it is manifestly herpetic. The very course which it runs proves it to be different from pure eczema. It generally yields promptly if merely let alone, or under any simple treatment, and shows no tendency to come back again and again, which cannot be said of eczema. It is true this arrangement is quite antagonistic to all established views, and clashes with the pathology of Plumbe and Willan, but the fact is, that the eczema of Plumbe simply embraces solare and mercuriale; he never alludes to the same affection now-a-days called eczema as being a form of that complaint. Possibly he was influenced by the old view, which named our eczema scabies.* Any confusion, therefore, likely to arise from the change I desire to make, is due, not to a desire on my part to introduce novelty, but to the fact that what we recognise as eczema is a different complaint from that which was classed as such within quite a recent date. A new pathology has sprung up.

The chronic form of eczema, in a vast majority of cases, begins as an eruption of papules; in rarer instances, as an erythema or pityriasis. These may, therefore, for the present, be laid aside, in order to examine acute eczema, which we might expect to find more closely connected, if any form of eczema can be connected, with vesicular disease; but the more narrowly we examine it, the more certain does the conviction become, that its course and symptoms ally it rather to an acute erythema, erysipelas or kerion (scalled head). In this form of eczema a large portion of skin, as the forehead, for instance, becomes red, swelled, glazed, and stiff. This is followed by desquamation of the cuticle, and the formation of moist scales, and even crusts, or there may be a slight, though decided, weeping. Now, an observer bent on finding out the truth, and not on merely supporting a theory, may see this over and over again in several persons, or several times in the same person, without ever finding a vesicle. I attended a gentleman for this complaint, who was a good deal alarmed about it, as an intimate friend of his had been quite a martyr to eczema. For eighteen months the patient scarcely ever passed any great length of time without an outbreak on the face, yet on no occasion could either he or I detect a single vesicle.

* "I have no doubt that the minute ossicular form which the disease assumes when occurring from exposure to the sun, is materially dependent on the degree of heat applied; that a blister of the skin would occur if the heat were increased, while a minor degree of the latter would only be followed by eczematous redness; that it is, therefore, rather to be considered as an accidental injury, and treated on surgical principles in a manner similar to a slight burn or scald, than to be spoken of as a disease."—Plumbe "On Disease of the Skin." 1829. Pp. 353.

* "The disease which the ancients described under the name of scabies is identical with that disease which at present time we call eczema."—Dermal's "Pathology of Celsus."

A CASE OF ACUTE RHEUMATISM TERMINATING FATALLY ON THE FOURTEENTH DAY.

By Michael W. Sheedy, M.D.

On the morning of Sunday, the 19th of June last, I was called to attend J. C., æt. twenty-five, a young man of rather delicate constitution, and very respectably circumstanced in life. Upon enquiry I learnt his previous history as follows:—He was through life of very regular and temperate habits, enjoying rather good health, of pale and languid expression of countenance, with a chest somewhat narrow and receding. About six weeks before he sprained one ankle, and about the same time indulged in a slight spree during two or three days' racing in the neighbourhood. The above, in addition to pumping cold water on the sprain and damp clothes for one evening were the preliminaries to the attack which followed.

His friends having administered a vapour bath and some aperient medicines, sent for me, as the patient, they said, spent a wretched night. He seemed to me to be suffering great pain with a very anxious expression on face, the weight of the blanket on the feet and hands being intolerable. I bridged over the wrists and ankles, which were swollen, to keep the clothes off, and ordered the following:—

℞ Calomel, grs. v.;
Pulv. jal. ce., gr's. xx.;
Pulv. stat. sumend.

℞ Potas. bicarb. grs. ccccIxxx.;
Nitrate, grs. cxx.;
Vini. colchici., ℥ij.;
Aquæ camph., add ℥x.;
Mist. St. ℥ss, tertiis. horis.,;

Giving an anodyne liniment for the feet, I desired them to be bandaged in cotton wadding. Next day the medi-

cine having operated, and the pains a little less, he was slightly better, but the fever was in full force, viz., great heat and perspiration, urine scanty and high coloured, specific gravity, 1,025; pulse, 112. Ordered some chicken broth or beef-tea, a little arrowroot and a-half glass of sherry every second hour, continue medicine as before. Tuesday much the same, I prescribed, viz.,

℞ Mag. sulph., ℥j.;
Potas. acid tartrat., ʒij.;
Lucci. simon., ℥js.;
Aquæ, q. s.

which acted same evening; no better on Wednesday. On Thursday morning he woke out of a troubled sleep in an angry manner, insisted on getting out of bed, which he did; he was still very bad, when on Friday 2.30 p.m., I had a note saying he was in a dying state, and asking if I could see him at once. There was now a well marked bellows murmur accompanying the systolic sound of heart, a great deal of bronchial effusion, and pain in the base of both lungs posteriorly. I now applied a blister to præcordia, ordered ℥j., of mercurial ointment to be rubbed into both groins, ʒij., at each half hour's interval, with a small mustard plaister to base of each lung. Seeing him on next day, the murmur was almost gone, the sense of oppression at præcordia was vanished as also the pain at base of lungs, but on this day, Saturday 25th, a very ugly diarrhœa commenced, some very black looking stuff containing semi-liquid bloody pellets of mucous in the discharge, as a consequence great prostration ensued, to remedy which, I administered five drops of turpentine in a-half glass of brandy every second hour, with an opium suppository, which had the desired effect. Still not satisfied with his state, I asked for a consultation, which I had that evening. My consultee advised some quinine and iodide of potash mixture, which did not relieve any of the symptoms. For the next three days, there was certainly only a very imperceptible improvement, and on Thursday the 30th, I, for the last time, saw him alive at 1.30 p.m., when I found the heart had again resumed its abnormal murmur partially, the decubitus on the back, coma vigil subsultus tendinum, (a ticking in the ears) with great flaccidity of the body; which, though making my prognosis very fatal, still it did not lead me to think death was so near at hand. I may also add that his thorax and neck were the seat of a vesicular, and partly pustular eruption, which appeared on the previous night, and also that patient was seen so late as 11 p.m., the night prior to death by another medical man, and thought by him to be nicely. Patient died suddenly at 5 a.m., on Friday, the fourteenth day of his illness. Now, for information sake, I would ask those having more skill and experience than myself, to explain, viz.,—Whether bronchial effusion producing apnœa, mechanical obstruction to the heart's action, by a coagulum or effusion on the brain, by a clot from the heart was the cause of death so suddenly; and also what alteration they would suggest in the treatment according to the symptoms described above.

OBSERVATIONS ON FEMALE PHYSICIANS.

By Joseph Duggan, L.K.Q.C.P.I., Turloughmore, Co. Galway.

With reference to the subject of lady doctors, I am more than glad to find that the progress of the movement is more apparent than real; indeed, for their own sakes, I am delighted that it is so, as it has much of the *nihil admirari* about it. Not alone with surprise, but with regret, I find that some of my medical brethren have strenuously supported this audacious innovation; it does not redound to their credit for throwing this apple of discord into their own ranks. Oh! if the illustrious fathers of our noble profession could arise from the grave, and behold this moral degeneracy of their sons, they would indignantly exclaim, "Tarnish not the title deeds of the proud inheritance left you."

This pernicious and unsexing system of female education requires no great amount of logical acumen to expose its fallacies, which on moral, physical, and intellectual grounds are, to my mind, clear enough. I know every sensible man on a little reflection would at once see its glaring evils. The baneful effects it would have on the moral tone and well being of female civilised society, by turning the thoughts of woman from her own legitimate associations to assume the natural prerogatives of man. All the rights that she can attain in a medical point of view, she at present enjoys. In her own sphere, she is our "ministering angel," but as a physician, she is inadequate to the task. There will be a few, I know, and very few who, in order to gratify their masculine propensities, care not to erase those moral attributes and delicate qualities, which form the touching and graceful lineaments of the female minds, as contrasted with our own sex.

A few days ago I had the pleasure of conversing on this topic with a very well educated and sensible lady; she fully concurred with my views, and said it was one of those "freaks of her sex which she hoped they would abandon in time."

I think I have said enough on this point, and will not, therefore, insult the intelligence of my readers by saying more. *Verbum sap.*

Her physical incapacity is also very obvious; the weak and delicate frame of woman cannot bear toil and hardship like robust man; and I need not mention the fact that, country practitioners must endure wind and weather, riding and driving, often in frost and snow, at all hours. Let me imagine, for instance, one of these female doctors, perhaps married, getting a midnight call, a few miles distant. Away she must go—probably over mountain passes, ploughed fields, through highways and byeways, where no vehicle can go; only fancy her position, what a sad plight she will be in ere she arrives at her destination; and, as for her husband, his position is anything but enviable. On the other hand, if she is of the unmarried class, called spinster, there are some advantages gained, and she can manage a little better. If the Profession is, then, only suited for those spinsters, they will form a very small and isolated body indeed—a celibate sisterhood of Esculapian votaries, that condition which most of their sex will keep away from, if they can!

Then on intellectual grounds, woman has given us marvellous proofs of her great intellect and ability as historians, poets, novelists, and in every branch of language, literature, and the fine arts; and yet it is a remarkable fact, with a few rare exceptions, that she scarcely ever showed much capacity for acquiring a knowledge of the physical and natural sciences. She has not that aptitude or peculiar power of thought for abstraction and generalisation which is inherent in the male sex. In analytic and synthetic inquiries, she cannot compete with man. Woman never produced a female Newton or Laplace, a Bacon or a Linnæus. No; their minds are not moulded for such heavy work. Why, then, do they wish to dabble in the purely scientific Profession of medicine—one of the highest and most arduous studies that can occupy the mind of man, and the practice of it far more difficult still. See the physician at the bed-side; there he stands as judge, jury, and advocate combined; in fact, triple-minded. Contemplate on the powerful working of the brain, as he is reasoning with himself; consider all he has undertaken, and the great responsibility imposed upon him.

He must then have a clear and comprehensive knowledge of man in health and disease and a well developed brain, capable of great reasoning powers, tact and erudition. Without fear of contradiction, I may safely assert that woman is incompetent for such a task, and that she is wholly unfit for the profession, and can never meet the emergencies of medical practice. I hope the ladies will not consider the broad truths I have stated, as any way intemperate or uncourteous, I consider them perfectly per-

tinent, by showing how utterly inconsistent it is for ladies to adopt such a profession.

It is very odd they don't try the pulpit or the bar, where their high aspirations might have free scope for gratification and far more remunerative for their pockets than this noble but ill-requited Profession of ours. Ere long we might see a female Bossuet or a Fenélon, pulpit orators, glorious in eloquence, dealing not in thin generalities, but driving God's truths into the hearts of poor sinners. And at the Bar, their sharp wit and fervid oratory might some day wing one of them to the loftiest forensic honours.

"Major mihi rerum nascitur ordo."

I need not assure them what a happiness it would be to have the privilege of contemplating the probability of being one day crowned with a mitre, or robed on the woolsack. Nothing would give me greater pleasure than to see the intellectual genius of woman appreciated, and developed in the various walks of life, suitable, and not offensive, to her sex, nor unbecoming the character of woman.

Female physicians existed in former times, but they miserably fulfilled the duties of medical practice, accordingly they dwindled away, and became obsolete, succumbing to that obscurity which they adorned. They never wrote or did anything to improve the science or practice of medicine; with a few exceptions, our medical archives do not reveal any traces of their intellectual existence. My fair aspirants may rest assured that the same fate awaits them now; the female doctor of to-day will ere long vanish like a splendid phantom, to be considered in after ages as a dream of female medical fanatics. I would, therefore, exhort them to abandon this unnatural female calling; there is too much of the Amazon about it, and they may depend on it, its uphill work will not be so congenial a life as those allotted to her by nature, which the educated lady so gracefully fulfils, gliding amid the tranquil enjoyments of domestic life as a gentle and virtuous wife; her love is a paradise of delight, which dissipates the cold and indigent realities of life, and imparting with unobstrusive and fascinating manners that happiness which enchants the soul. Among her children, she is the attractive centre of love and affection—the oasis in the desert of their existence, the green spot to which their hearts' eyes turn, when they are sick and wearied of the false glare of the world around them.

Hospital Reports.

LONDON HOSPITAL.

We continue our abstract of the History of the London Hospital and its Medical College.

The entry of the first student took place in January, 1742, and annually from that time pupils were admitted to attend the practice of the physicians and surgeons. So early as 1749 Mr. Harrison obtained the permission of the House Committee to deliver a Course of Lectures on Surgery in the Court room of the hospital, and in 1757 a similar permission was granted to Mr. Thompson, another surgeon to the Institution. It is now more than a hundred years ago since Mr. Thompson performed at the hospital the first amputation of the hip ever done in this country.

In August, 1781, Sir William Blizard (to quote a Minute of the House Committee) obtained permission to deliver two courses of lectures on anatomy and surgery during the next winter in the Demonstrating Theatre of this Hospital; at the same time to obviate any reflections that may arise from the feelings of some persons, he engaged not to use (the remains of) any of the patients of the hospital. Thus almost from the foundation of the Hospital anatomical demonstrations and courses of lectures had been continued, but it had now become necessary to make more comprehensive arrangements for medical education. Owing to the absence of practical opportunities of studying anatomy and surgery at the English universities, as well as to the customs of the times, students proposing to practice as Surgeons were virtually excluded from the benefit of university education. From other causes the great mass of medical practitioners of the last century, the apothecaries, shared the privation. The advantage of forming a complete school of medicine in connexion with hospital became obvious, and the medical faculty of the University of Edinburgh, then in the zenith of its reputation, presented a model, which was, not improbably, imitated.

Accordingly it is stated in the *Public Advertiser* of March, 1788, that "The Physician and Surgeons memorialized the Governors of the Hospital to the effect that in their opinion the teaching of the several branches of physic and surgery by lectures at the Hospital would promote the credit and interest of the institution; that the present accommodations are inadequate to such an undertaking; they therefore requested leave to erect a suitable building." The result of this application was, that the General Court of Governors assembled February 5th, 1783, gave permission for the erection of a building at the east end of the Hospital, according to the prayer in the petition.

About £500 were collected in subscriptions from individual governors and friends of the hospital; the remaining portion of the expense of the old building (about £1,500) was guaranteed by two of the Medical Officers of that period, Dr. Maddocks and Sir William Blizard. Through the premature decease of Dr. Maddocks, the liability devolved mainly upon Sir William Blizard, who in this matter, as in others proved himself one of the most far-seeing and devoted friends of the hospital. Among the most active promoters of the undertaking was Mr. Samuel Davey Liptrap.

The London Hospital, therefore, enjoys the credit of having in 1785 set the first example of a complete Medical School in connection with a hospital upon the model of the Medical Faculty of an University. Moreover, the printed prospectus of the London Hospital Medical College for 1792 shows that in addition to the Courses of Lectures on the usual subjects of Medical Education, a *Course of Lectures on Clinical Medicine* was at that time given in the School. Subsequently, Clinical Lectures were discontinued, but they were successfully resumed by Dr. Billing in 1823. The building at the east end of the hospital continued in use until 1854, when the present Medical College was inaugurated. In the previous year, in compliance with the representations of the Medical Council of the School, the governors had decided to erect a spacious and convenient edifice for the purpose of meeting the enlarged requirements of Medical and Surgical Science, and of attracting to the London Hospital a Staff of Dressing Pupils adequate to the necessities of a great School of Practical Medicine and Surgery. The expense of erection, which amounted to more than £10,000, was borne by the governors of the hospital.

ST. VINCENT'S HOSPITAL, DUBLIN.

Report upon Fox's Palatable Cod-Liver Oil.

By Robert Cryan, L.K.Q.C.P., L.R.C.S., &c.,

Physician to the Hospital.

I have had the Palatable Cod-Liver Oil of the Messrs. Fox and Co. administered to several of my patients, and I am convinced that it has been of very great advantage to them. Some of my patients in St. Vincent's hospital, in whom the ordinary cod-liver oil in its natural state, or even combined with sulphuric ether, almost always produced unpleasant eructations and vomiting, found the Palatable Cod-Liver Oil of the Messrs. Fox and Co. not only agreeable to the taste but also easily retained upon the stomach. In that rather large class of cases where

the use of cod-liver oil is indicated, but, in its ordinary form, found to disorder the organs of digestion, I believe the administration of the Palatable Cod-Liver Oil will be highly advantageous. I may add that the dose of the Palatable Cod-Liver Oil should be nearly double that of the ordinary oil. Hitherto, I have not had very many opportunities of prescribing the Palatable *Castor* Oil, but, so far as my experience extends, I can report very favourably of it.

CITY OF DUBLIN HOSPITAL.

Report upon Fox's Palatable Cod-Liver Oil.

By John Hawtrey Benson, A.B., M.B. &c.

My experience of Fox's Palatable Cod-Liver Oil is decidedly in its favour. I have usually found that the delicate patients take it with ease, and do not perceive the disagreeable characteristic taste of cod-liver oil, except slightly as a after-taste. It is not strictly true that it does not "rise" from the stomach after it has been taken. But it is relatively true, for it does so very much less than any other specimen of cod-liver oil I have prescribed. The Palatable Oil can be, therefore, taken in larger quantities than other cod-liver oils, and when so taken I consider its therapeutical value not inferior—perhaps superior—to that of other oils.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, December 13th, 1870.

Dr. Burrows, F.R.S., President, in the Chair.

temporary glycosuria as a sequal of cholera.

By William Sedgwick, M.R.C.S., L.S.A.

After a brief historical retrospect of the subject, the author remarked that, in studying the character of the urine in cases of cholera, attention should in the first instance be directed to the fact that the first and albuminous urine passed or withdrawn after the usually prolonged suppression of the secretion was usually deficient in urea, and free from sugar; and that the subsequent condition of temporary glycosuria was preceded by the occurrence of a blue colouring matter, which appeared to be intimately associated with saccharine transformation. It was a significant fact that sugar in the urine occurred not, as a rule, in the first urine secreted after a more or less prolonged suppression, but subsequent to the occurrence of albumen; and that whilst there was during the early stage of cholera convalescence a relative deficiency of urea when albumen was present, sugar, on the contrary, was associated with urea in excess. The deficiency of urea which occurred in connexion with the albuminous urine of cholera was the more noticeable from the fact that, as the amount of urine secreted within a given time, after the previously complete suppression of it, was small, the proportion of urea should have been relatively increased, if the development of that organic principle in the system had been uninterrupted; and consequently it might be suggested that, as urea had been found to be one of the best diuretics, the suppression of urine which occurred in cholera and in allied conditions of the system resulting from poison or from disease, admitted of being directly referred to temporary arrest in the formation of that excrementitial product. The production of the blue colouring matter in the urine of patients suffering from cholera was chiefly important from the fact that it was very closely associated with the development of glycosuria; the occurrence of sugar in the urine in such cases appearing to be simply a somewhat later stage in the series of pathological changes which, so far as they affected the urinary secretion, could be traced to one common origin. Attention was directed to the frequency of the occurrence of a blue colouring matter in the urine in a great many other diseases which, like cholera, admitted of being more or less directly referred to the alimentary canal; and it might be suggested as probable that, as sugar had also been found in the same class of cases, these two abnormally increased, if not altogether abnormal, constituents of the urine were due to the same cause, and derived from the same source. In reviewing the pathology of the urine in cholera, the chief facts to which attention should be directed, with reference to the occurrence of glycosuria, were—the suppression of the urinary secretion as a primary result of the disease, with arrested formation of urea; albuminuria, with deficiency of urea; the presence of a blue colouring principle; and, finally, diuresis, with excess of urea and sugar in place of albumen. In the sequence of phenomena there indicated, urea as the essential principle of the urine necessarily occupied the chief position; and the subsequent presence of sugar during the stage of convalescence, when albumen was no longer present in the urine, suggested that the temporary glycosuria of cholera might be due rather to the progress of reparation than of destruction, and that it was, as it were, the result of an excess of restorative effort on the part of the system to repair loss from previous disease. This suggestion derived support from what occurred in diabetic patients during an attack of fever, when sugar in their urine was apt to be replaced by albumen; and by what occurred in the same class of patients during the last agony, when a similarly retrograde course with respect to the pathology of the urine was pursued; for in them also the urine became albuminous, and the sugar disappeared; and it was moreover supported by a large amount of collateral evidence which was almost conclusive in its favour. It would be found useful, in studying the character of the glycosuria which had been observed during convalescence from cholera, to take into consideration the various physiological, pathological, and artificially produced states of the system in which, as in cholera, sugar was commonly present in the urine without giving rise to confirmed diabetes. For temporary glycosuria, like the previous suppression of urine, had no claim to be regarded as an exceptional phenomenon, which was in any way characteristic of cholera; but, on the contrary, it would be found to occur during convalescence from other forms of acute disease, in which it was often associated with the previous development of a blue colouring principle in the urine. It would be found also to occur, apart from disease, as a physiological condition during certain stages of development, and at certain epochs of life. And, finally, that it admitted of being experimentally produced. With reference more especially to the occurrence of temporary glycosuria in the latter class of cases, as a result of sympathetic nerve section, the author remarked that in all experiments of that kind the primary effect produced must be on the vascular system to which the branches of the sympathetic nerve were distributed, and that any effect produced on other parts of the organism must be secondary to that. Consequently, whilst recognising vascular paralysis as the primary result of section of the sympathetic nerve in all parts of the system, it was important to notice that in the secondary results produced no such constant uniformity had been observed, since these were liable to vary according to the locality in which the experiment had been performed. He was of opinion that, with regard to the occurrence of temporary glycosuria as a sequel of cholera, there was no fact in experimental physiology more significant than that observed by Eckhardt in 1867, of the absence of sugar from the urine after section of the splanchnic nerves, which, taken in conjunction with the fact observed by Morcau in 1868, that section of those nerves was followed by an intestinal flux, possessing the same characters as the flux of cholera, indicated very clearly the direction in which the inquiry should be pursued. For when the neuro-paralytic condition of the digestive canal so produced was compared with what occurred after the influence of the central portion of the sympathetic nervous system had been artificially increased by the application of galvanism or electricity to the part during life, as shown in MM. Linati and Caggiati's experiments, it would be found that the results then obtained were essentially opposed to those which followed arrest or diminution of that influence, either from section of the nerves or from cholera.

In conclusion, the author remarked that the temporary glycosuria which had been observed in all the various cases which he had cited might be regarded as a consequence of long-continued and immoderate secretion, consequent on a previous diminution or arrest of the influence of the sym-

pathetic or vaso-motory nervous system, which apparently occupied a position functionally midway between the secretory surface on the one side, and the supply of blood on the other, and thus became the moderator of secretion in virtue of its action as controller of the circulation. From his observations on the subject, he had been led to infer that all secretion was associated with saccharine transformation; and that whilst, on the one hand, an excess of secretion was accompanied by a corresponding excess in the formation of sugar and consequent glycosuria, a moderate exercise of secretory function was, on the other hand, accompanied by a correspondingly moderate formation of sugar, which was not more in amount than could be disposed of in the system; and that it was only when the blood contained sugar in excess from such causes as those which had been already referred to that some of it was, in consequence, eliminated by the kidneys. Consequently, it might be urged that the temporary glycosuria, which occurred as a sequel of cholera, served to show that during reaction from previous collapse there was a temporary excess of restorative effort, and that although, as was well known, an abortive attempt at reaction was in that disease a very common cause of death, yet in those cases of cholera which terminated favourably, and in which glycosuria had been observed to occur during convalescence, the subsequent disappearance of sugar from the urine might be accepted as evidence in favour of the normal balance of organic function having been satisfactorily restored, and that the tendency to excess during recovery from a central arrest of nutrition had ceased.

THE SURGICAL SOCIETY OF IRELAND.

The first meeting of this Society for the Session of 1870-71, was held on Friday evening, December 9th, in the Albert Hall, Royal College of Surgeons.

Dr. Albert Walsh, President of the College, in the Chair.

Dr. Richardson having read the minutes of the last meeting.

The President delivered his Inaugural Address, which will be found at page 517.

REGENERATION OF BONE.

Dr. Kelly exhibited a hand which had been removed from a man, who had received a bite from another man on the thumb. The case he said was interesting, owing to the reproduction of the terminal phalanx of the thumb, which had been removed with its tendons and ligaments attached, and presumedly with its periosteum also. As it was removed in its entirety with its periosteum, the regeneration could not be accounted for by the ordinary theories of the regeneration of bone which had been advanced,—that the new bone was produced from the remains of the original bone, from the original bone before its complete death or from the periosteum. The case he thought was valuable, as indicating an analogy with the independent reproduction occurring in the Radiata and the Articulata.

INJURY OF THE HAND.

Dr. Wharton, V.P., exhibited an example of a machinery accident which had been brought into the Meath Hospital on the 6th instant. The subject of it, was a youth, fourteen years of age, engaged in Messrs. Pim's factory at Green mount, who unfortunately introduced his hand into a portion of the machinery, and was so injured that amputation was necessary. The entire integuments of the palmar surface of the hand were stripped up, and converted into a pulpoid mass. Upon removing the hand, all the metacarpal phalangeal joints were found to be dislocated towards the palmar surface, and the same thing had happened to the thumb; so that it would appear, after the integuments of the hand were stripped off the fingers the latter were dislocated towards the palmar surface. As soon as reaction was established the hand was amputated. There was but little hæmorrhage, and the boy was doing well.

VESICAL CALCULUS.

Mr. H. G. Croly exhibited a small calculus which he had removed from the bladder of a boy, five years of age. The child had been suffering from the time he was two years of age with many of the symptoms of stone. When only two years old, the mother noticed that he pulled at the prepuce, and had considerable pain in making water. The symptoms went on and she treated the boy for worms, but finding that he did not get better, she brought him to Mr. Croly, who having placed him under the influence of chloroform, sounded him and struck the stone. The boy was admitted to the City of Dublin Hospital and a few days ago the lateral operation for stone was performed. One of Mr. Croly's reasons for bringing the case forward was, because he had experienced considerable difficulty in getting the stone out of the bladder, which was unusual in a child. The operation was performed with a staff grooved in the side and with a single knife. The knife was got readily into the groove of the staff and he got his finger into the bladder without any trouble, but then he could not find the stone. He should mention, that in sounding the child in the presence of his colleagues, it was on the withdrawal of the sound from the bladder that the stone was struck, and by that he learned that the stone used to get behind the pubis. This point he considered to be one of some interest. He got the stone out by tapping the child on the anterior part of the abdomen when the calculus, but afterwards the stone from its small size and flattened shape, escaped from the forceps and ascended into a pouch behind the pubis, so that it was twice up in that situation and gave him some trouble in extracting it. They all knew that one of the great difficulties in performing the operation of lithotomy on a child was getting into the groove of the staff. He thought this difficulty occurred more frequently from the want of proper height in the operating-table than from any other cause. The table should be of such a height that the bladder would be above the operation, so that they would look up to it as an abdominal and not as a pelvic viscus. After the operation in this case, a chemisette catheter was introduced, and the child had gone on well with the exception of a slight attack of bronchitis.

In reply to Dr. H. Kennedy, Mr. Croly said he had not heard of any blood having passed from the bladder previous to the operation.

SYPHILIS.

Mr. John Morgan introduced for discussion the subject of the "Duality of the Venereal Virus," and said he should be glad to hear the opinion of the members of the Society on that much debated question. Every one was conversant with the continental theory of the existence of two sores, the infecting and the non-infecting sore, but lately there had been some change of opinion among writers on this subject, and perhaps the most striking one was that of Mr. Bumstead. Those who had read that gentleman's most carefully written book, were aware that he mentioned two kinds of venereal sores. He even gave in his book, a comparative column between the symptoms of the two. He (Mr. Morgan) had, however, received a letter from him within the last two months, in which he stated that he had found reason to hesitate in confirming what he had previously so anxiously endeavoured to impress. If a writer of Mr. Bumstead's experience, and who had written so largely on this particular subject was now inclined to hesitate and doubt as to his former views, the Society, he thought would agree that the question was worthy of discussion. He (Mr. Morgan) had lately performed some experiments at the hospital, by inoculating patients already affected by syphilis or constitutional venereal virus; and he invariably found that the result of the inoculation was the production of the ordinary chancroid or soft sore. The question was, whether a patient not already the subject of syphilis, if inoculated was capable of producing a hard or infecting sore. He had never been able to succeed in getting a hard sore by inoculation, but then of course he had never tried the experiment on a previously healthy person. Ricord and others, asserted that after some time the hard sore was capable of degenerating into a mucous tubercle. Now, if they took a mucous tubercle and inoculated with it as he had done, they would find the invariable result in a syphilitic patient was the production of a soft sore or chancroid. Inoculation from a true chancroid would produce a chancroid—and inoculation from a bubo, or from a vaginal discharge would invariably produce in a patient, already constitutionally affected, a soft sore. In performing these experiments of inoculating from a vaginal discharge, he had taken the greatest pains to satisfy himself that there was no abrasion of the surface, no intra-vaginal or uterine sore. He had performed over two dozen of experiments, and invariably produced the specific pustule and the peculiar sore well known as the chancroid or soft sore. The only point to be considered was what would be the result, if the experiment had been performed on a non-infected patient and he would be glad to hear from any member of the Society, who might have had an opportunity of ascertaining it, whether the result of inoculation in such a case would be a hard sore or a chancroid. He had

taken the vaginal discharge and produced a soft sore, from that soft sore he produced another, and from it another and so on, all the result of the original inoculation with the vaginal discharge. If it were the case, as many continental writers affirmed, that sores had been communicated to men by women who had no abrasion or breach of the surface themselves, they must come to the conclusion that the sores were caused by inoculation with the vaginal discharge. In the Lock Hospital, nearly all the patients were affected by soft sores, and they had been invariably followed by secondary symptoms; and over and over again he had inoculated from these sores. These results were directly at variance with the opinions expressed by many eminent writers on this subject. They were all aware that a vast difference of opinion existed in reference to it. In America Gross differed from Bumstead; and in England we had such men as Syme and Sir William Fergusson, holding that there was no such thing as a dual poison, while others of equal authority held the reverse. The question was whether this dual sore existed? Was there one sore capable of infecting and another that was not? All the patients who were affected with sores in the hospital under his charge had secondaries, yet the hard sore were very rare indeed. He had seen as good a type of this hard sore in women as he had seen in men, but hard sores were very rare, while soft sores were frequent, and yet all the patients suffered from secondaries. These patients were the chief sources of venereal sores in Dublin. The inoculation test confirmed the theory that there was not a dual sore. He should say that he thought women suffered more from constitutional symptoms than men. Women who got soft sores did not escape, while men sometimes did. In *Hayes' American Journal* for August last, Mr. Bumstead had an article in which he said it made no matter whether the material for inoculation were taken from a hard sore or a soft sore, he found the result equally the same. The theory was, that if a person be already affected by the hard sore, he should be incapable of inoculation again; but now we had Mr. Bumstead saying that you can inoculate from the hard sore. The hard sore, if irritated, would produce pus, and he (Mr. Morgan) had in his possession some pus sent from Christiania, which had come from a hard sore which had been irritated by savine powder. This pus thus produced had been inoculated on a patient already suffering from constitutional symptoms, and it produced a soft sore. It was found that a hard sore was capable of degenerating into a mucous tubercle, and if they inoculate from a mucous tubercle it produced a soft sore; and this brought the matter to a focus—whether there was a difference between these two venereal sores—one sore capable of infecting, and the other sore not? The treatment of syphilis by inoculation was very interesting. He had inoculated, as he had already said, patients suffering from constitutional symptoms with vaginal discharge; the soft sore was produced, and the patients invariably got well. He should add that the sores he produced by inoculation, including those produced by the pus sent him from abroad, were rather persistent. What he was anxious to do was to draw the attention of the Society to the question—Was there a distinct line of demarcation to be drawn between the two sores? What was the experience of the members on that point? If they were of opinion that there were two distinct sores, it was an extraordinary fact that in hospital they seldom or ever saw the hard sore, and therefore must come to the conclusion that, if the two kinds of sore existed among males, they got it not merely from the hard sore but from any form of sore. There was another point to which he wished to refer, namely, that sores, as a rule, were not so frequent as was supposed. The general account which women gave was that the first thing they noticed was a discharge. Male patients have come to him saying, they got a sore from such a woman; but when he came to examine her she was found not to have a sore at all. The women say the first evidence of their being affected is a discharge, then comes a sore, then a mucous patch, then an affection of the skin, &c. It was not very difficult to believe this, for if you can take the vaginal discharge and inoculate with it, producing a soft sore, he did not see why a male patient, having some slight fissure or abrasion of the surface, might not be infected by the vaginal discharge only in the course of direct connection with the female. Then came the great question which he had already dwelt upon, and on which he desired to elicit the opinions of the members of the Society, what would the result be in a person not previously tainted with syphilis? He thought it would be a soft sore. Sometime ago a gentleman came to him with a soft sore, and in three weeks after that a vigorous gonorrhœa occurred. It seemed to him extremely likely that the same discharge gave rise to the gonorrhœa and the soft chancre or sore.

Dr. Barton thought it rather an unfortunate thing that their views on this subject should be rather disturbed than settled by Mr. Morgan's experience. He could not follow his statement so accurately as to be able to discuss it in detail; but it struck him as the general result of what Mr. Morgan said that his (Mr. Morgan's) own mind was considerably confused on the subject, and for this reason—he incidentally let fall that he was not quite sure what gonorrhœa was, and suggested that perhaps it was generated by means of the introduction of the second poison, intimating that he was not sure there was a second poison. The general conclusion of Mr. Morgan threw serious doubt on the views heretofore entertained, but did not satisfy their natural desire by establishing anything clear or definite as to the nature of these different sores. He (Dr. Barton) believed there were two different kinds of sores, one of which ran a local course, whereas the other was the commencement of a constitutional disease. He thought the observations of Mr. Morgan went to prove that perhaps they were hasty in speaking of two distinct poisons. They should say rather that there were two distinct diseases, and their object should be to clear up what were the signs by which they knew one disease from another. Many of the points mentioned by Mr. Morgan were old. They knew that the discharge from a syphilitic woman might produce sores, although there were no sores on them, and that these discharges when inoculated would produce soft sores was already well established. The fact that a vast majority of the patients in the Lock Hospital had ordinary soft sores, and that they were followed by constitutional symptoms, was a very important matter. He thought that in these women it was absolutely impossible, in the early stage of these sores, to say which of the two diseases they were. It required very great accuracy of observation to clearly establish anything of this kind, and in the patients Mr. Morgan had to deal with, the difficulty was increased, for they were exposed to contagion of every form. He repeated that it was necessary cases should be noted with great accuracy before they were accepted as overturning a great amount of evidence which existed, to prove that the two sores are in their early stage not easily known, and that observation was required to tell them from one another. The whole subject was one of great difficulty. The object of his remarks was this, that he did not think the observations and experiments of which they had heard went further than to show that in women the early stage of true syphilis was not marked by the characteristic indurated or hard sore; but they had no right from that to infer that the chancroid or soft sore was the only true source of the disease.

Dr. Stapleton said there was an old French author, Diday, who said he believed inoculation from secondary syphilis produced the soft sore, and not the hard or true contaminating sore—the Hunterian chancre. He recollected last year bringing before the Society the case of a gentleman who came to him with a number of soft sores, and on the 18th or 20th day afterwards they were beginning to heal when a hard chancre declared itself. After a great deal of questioning he acknowledged to having had a second connection in the interval. Another person came to him with a nest of chancres, some ten or twelve. The lady who gave him the disease was examined by another medical man, who pronounced her to be perfectly sound, but she might have had a vaginal discharge. It had been laid down that if a man had a hard sore, he might be inoculated with the soft sore, but it had a tendency to run into phagedena. Of course, it would not be justifiable to inoculate a clean subject with any form of this disease. It was extremely difficult to find a true Hunterian chancre in a state to inoculate from. He had known cases which went on to secondaries, and yet the patients did not know they were contaminated. From his own experience, he firmly believed there were two distinct poisons; and, moreover, he believed if a man got a regular hard chancre, he did not care how he was treated, with mercury or other medicines, he would get secondary symptoms; whereas the man with a true soft chancre would not. Instances had occurred in which discharges from the urethra had been treated as gonorrhœa, whereas, on a more accurate examination they were found to result from soft chancres in the urethra.

Dr. Macnamara.—Do you say a soft chancre is not followed by secondary symptoms?

Dr. Stapleton.—Yes, if it is a true soft chance you may cure it with mercury; whereas you cannot cure a hard chancre with mercury.

Dr. Hamilton Labatt was surprised to hear it said that a soft chancre was never followed by secondary symptoms. When he was a mere student in hospital he saw a variety of cases in the wards in which secondary symptoms had followed from the soft chancre. If secondaries only followed hard chancres they ought to be very rare, for hard chancres were very rare; yet the fact was that secondary symptoms were very common.

Dr. Macnamara said the subject was one of great importance, and could not be adequately discussed that evening; and it was important that it should be properly discussed in a city, the surgery of which was so intimately associated with the subject of syphilis. He, therefore, moved the adjournment of the debate until the next night of meeting.

The motion of adjournment was agreed to.

DUBLIN OBSTETRICAL SOCIETY.

Second Meeting, Dec. 17.

Communications:—

1. Dr. Atthill "On some Forms of Enlargement of the Uterus."

2. Dr. J. A. Byrne "On Vaginal Tumour, and Prolapse—Removal—Recovery."

3. Dr. Johnston.—"A Clinical report of the Rotunda Lying-in Hospital for the Past Year."

Dr. Atthill read a paper

ON SOME FORMS OF ENLARGEMENT OF THE UTERUS.

After passing an encomium on the uterine sound, which he considers to be not only one of the most useful, but also the safest instrument we possess, if carefully and skilfully used; he proceeded to say that enlargement of the uterus was met with in a very large percentage of those cases in which the symptoms are referable to the organs of generation in the female, a condition easily explicable when the great change which takes place in the uterus under the influence of pregnancy, and even, in a degree, at each menstrual period, is borne in mind. The following, apart from the actual existence of pregnancy, are the causes to which most frequently enlargement of the uterus is due, namely to—

1st. Sub-involution of the uterus after pregnancy, or abortion,
2nd. Congestion of the uterus from sudden suppression or retardation of menstruation.
3rd. Acute inflammation of the uterus, or its peritoneal covering.
4th. Chronic inflammation of the uterus.
5th. Hypertrophy of the uterus.
6th. The stimulus given to the uterus by the presence in its walls of fibrous tumours.
7th. The existence of any form of intra-uterine tumours.

With respect to sub-involution, it was very frequently met with, being a condition specially likely to occur in cases in which any form of pelvic inflammation follows delivery. It may also occur after abortion. The earliest symptom of sub-involution, and the most common is, undoubtedly, menorrhagia, a symptom nearly invariably present. Dr. Atthill, however, narrated a case of sub-involution of the uterus, in which amenorrhœa existed. The uterus in this case was very large, the sound penetrating to the depth of five inches. This patient was perfectly cured, the treatment adopted being the introduction up to the fundus of the uterus of eight grains of the solid nitrate of silver, which, dissolving, stimulated the whole of the inner surface of the uterus, and caused healthy interstitial absorption to be set up. Dr. Atthill advocated this plan of treatment in cases of enlargement of the uterus depending on sub-involution. The occurrence of enlargement of the uterus from sudden suppression of menstruation was next dwelt on; the occurrence of this form of enlargement is difficult to verify. Dr. Atthill, however, stated that he believed it to take place not unfrequently, and gave the particulars of a case in which the measurement of the uterus, by means of the sound, proved this to be so. All writers mention the liability of the uterus to enlarge during an attack of acute inflammation of that organ. The correctness of this was confirmed by the details of cases in which, by the introduction of the sound, the increase in size and subsequent diminution was proved, in instances both of metritis and peritonitis. Chronic inflammation of the uterus appears to be a very common cause of enlargement of the uterus, and gives rise to much distress. It is often associated with retroflexion, not unfrequently being the cause of that displacement. Menstruation was stated to be, in the writer's opinion, generally much diminished by the occurrence of chronic inflammation. Of all the cases of enlargement of the uterus, simple hypertrophy of the muscular tissue of the uterus is that giving rise to the greatest amount of distress, and the form least capable of being benefited by treatment; in it menstruation occasionally becomes painful, sometimes scanty, but seldom, if ever, increased in quantity. Cases illustrating this, and each of the other forms of enlargement of the uterus, were detailed and commented on, and the paper concluded with some general observations on treatment. The consideration of the other forms of enlargement of the uterus being deferred to some future occasion.

Dr. Roe submitted to the Society a specimen of a

CYCLOPS MONSTER.

The case was the fifth child, and the presentation was of the shoulder. Zedemann was of opinion that the deformity arose from absence of one olfactory nerve. There had been much difficulty in ascertaining that the case was not one of twins, especially as the shoulder presentation in cases of cyclops monstrosity was very unusual.

Dr. Ringland remarked on the fact that on the first call of the case, the placenta and funis were found low down in the vagina. He believed that the placenta was low down in the cervix, and that a partial action of the uterus about its neck had expelled the placenta as the first act. The very extensive bruit had decided the operator not to eviscerate without a persistent attempt at turning a very large fibroid which had been found in the interior wall of the uterus, so that the uterus after *post-mortem* was almost as large as that of pregnancy.

Dr. More Madden narrated a case of a prostitute occurring under his case. The child had lived for an hour and twenty minutes, and on *post-mortem* examination it had been ascertained that there was but one optic nerve. The woman in this case had attributed the monstrosity to a fright, and Dr. Madden was under the impression that the Profession was over-hasty in rejecting the theory of maternal impression.

HARVEIAN SOCIETY OF LONDON.

Dec. 1st, 1870.

Dr. W. F. Cleveland, President, in the Chair.

Dr. Westmacott related the case of a child, five months old, who died after vaccination. The mother accidentally cut the child's thumb, which bled greatly, and was followed by an abscess near the biceps muscle.

Dr. Thomas Ballard read a paper

ON APOPLEXY,

basing his remarks upon the records of cases, which had occurred under his own observation. Headache, giddiness, and vomiting, usually precede insensibility, palsy and death. This was a chain of symptoms which he thought to be well represented by the term apoplexy—the first three to be regarded as the earlier, and the last three as the later stages of the disease. This succession of symptoms occurs alike in both sexes, and at all ages. The point of treatment urged was, that for the cases indicated a judicious abstraction of blood was the remedy beyond all others which was useful, and in many cases was the only one required.

December 15th, 1870.

Dr. W. F. Cleveland, President, in the Chair.

Dr. Wynn Williams showed a patient, æt. fifty-four, who had an epithelioma of the lower lip removed by Mr. Cooper Foster, in Oct. 1869. The man had been a great smoker of clay pipes. The disease returned, and Dr. Williams injected it six weeks ago with a solution of bromine 20 minims to ʒj of rectified spirit. About 10 minims were injected into the soft parts on two separate occasions, and the whole mass sloughed out. The slough took fourteen days to come off. The smell was horribly offensive, but this was relieved by an iodine lotion, ʒiij. of tincture to ʒviij. the water. The lip was so contracted, that a second operation could not have been performed with the knife.

Mr. Fairlie Clarke read a paper on

SURGICAL DRESSINGS.

The author after touching upon the importance of the subject in its bearing upon surgical practice and "hospitalism" drew a contrast between two methods which are in vogue at the present time—the method of Professor Humphry, who leaves all wounds as far as possible, entirely uncovered, and the "antiseptic method," as practised by Professor Lister. The author of the paper strongly advocated the use of antiseptic lotions of various kinds, but he thought that the "germ theory" ought to be investigated on its merits as a question apart, and that the use of carbolic acid, chloride of zinc, &c., ought not to depend in any way upon a theory which is still *sub judice*. He (Mr. Fairlie Clarke) insisted upon the need of styptics, prompt and efficient means of arresting the flow of blood as the most important step towards bringing about immediate union or primary adhesion.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Friday, Dec. 9th, 1870.

Dr. Clapton, F.R.C.P., President, in the Chair.

Dr. J. S. Bristowe read a paper entitled,

CASES ILLUSTRATIVE OF THE VARIOUS FORMS OF IMPAIRMENT, OR LOSS OF THE POWER OF SPEECH, WITH REMARKS.

The author, after stating that he had nothing new to announce, or even to suggest in reference to aphasia, proceeded to explain the mechanism of speech, which he divided into two associated, though entirely distinct, parts—that furnished by the larynx and that furnished by the mouth. Through the mechanism of the larynx is produced musical intonation; through the mechanism of the oral cavity are evolved articulate sounds. It is not surprising, therefore, that in disease we sometimes find the musical element of the voice affected, at other times the articulate element, that in the one case the patient speaks in a whisper—he has lost his voice as the phrase goes—that in the other case he retains his "voice," but cannot utter intelligible sounds. Dr. Bristowe then proceeded to consider aphasia under three heads—First, that due to a mental defect, independent of any affection of the organs of speech. To this form the name amnesia has been applied, or by Dr. Ogle the equivalent term of amnemstic aphasia. Particulars of four well marked cases of this condition were given; in all, the patients were paralysed on the right side, in other words, the left side of the cerebrum was diseased. The first case was one of very slight, but very distinctly marked amnesia, the affection of the brain being, doubtless, due to some small effusion of blood either into the corpus horatii or its neighbourhood. The second case was also one of slight amnesia, arising in connection with paralysis agitans of the right side, both conditions being, doubtless, dependent on some affection of the left cerebral hemisphere. The patient had heart disease, and Dr. Bristowe believed the symptoms were due to some softening of the brain substance, following the plugging of some of the small arteries. The third case was also one of hæmorrhagic hemiplegia; the amnesia being remarkably well shown, and was all the more evident from the fact of its being associated with a great deal of intelligence, and even liveliness of manner. The fourth case has also an exceedingly well marked example of amnesia, probably dependent on effusion of blood. These cases, to a certain extent, confirmed the views of Dr. Dax and M. Broca, these writers associating aphasia with disease of a definite part of the cerebrum, viz.—the posterior part of the third frontal convolution—the convolution that is in front of the hilum of Rolando. Dr. Bristowe considered, however, that although we might be inclined to agree with Dr. Maudsley, that further experience would show that impairment of speech belongs equally to affections of both hemispheres, that there was no doubt whatever that up to the present time aphasia has been found associated in a vastly preponderating degree with disease of the left side of the brain, and that it was quite certain, as Trousseau maintains, that aphasia is, in some instances, obviously the result of disease of the right hemisphere; and that it was equally certain that the dependence of aphasia on disease of a particular convolution, whether on the right or left side, was at present far from being a matter of certainty. The second form of aphasia was that in which, without there being any apparent mental defect whatever, and without there being any trace of paralysis of the organs of speech, the patient loses the power of speech absolutely. Particulars of one exceedingly interesting case of this form were given, in which Dr. Bristowe succeeded in teaching the patient to speak, a full account of which is published in the last volume of the *Transactions of the Clinical Society*. In a typical case of this kind the patient retains his memory and all his mental faculties; if he could read and write previously he can read and write still. In fact, he is in the condition of a person born mute who had never been taught to speak. It would seem indeed, Dr. Bristowe considered, that speech when once acquired is as purely a reflex phenomenon as are the acts of deglutition or respiration; that there is some ganglionic centre intermediate between the cerebrum (which thinks and wills) and the nuclei of the motor root of the fifth, the portio dura, and the hypoglossal (whence the motor power of the organs of articulation is derived), intimately connected by nerve fibres with all these parts, which, when the mind wills to express itself in words, acts as its agent in the matter, and directs the necessary combined impulses of the nerve nuclei, upon which the combined movements essential to the production of each articulate sound and each articulate word depend. If this be the arrangement, and Dr. Bristowe thought it most probably was, it is easy to understand how disease which affects this co-ordinating centre, which cuts off the connection between the centre (the portion of the cerebrum which may be supposed to preside over the memory of words), and the nerve-nuclei, would render a patient mute, even while retaining his knowledge of language and unimpaired intelligence. The patient would will to speak, but the agent on which he had hitherto relied would fail to obey his will, and here a something incomprehensible to himself would intervene between his will and its execution, and he would remain silent. The third form of aphasia was that in which the nerves of speech were paralysed, either from disease in the course of their trunks, or from some disease affecting their nuclei of origin. In these cases the patient fails to speak, not because his memory of words or his mind fails him, not because his co-ordinating power is lost, but because the organs of speech themselves are paralysed. Particulars of one case, illustrative of this condition were given, in which there was general paralysis, including paralysis of the organs of speech, caused by the formation of a small clot in the medulla oblongata. Dr. Bristowe stated that the most remarkable examples of this form are those furnished by disease of the medulla oblongata interfering with the origins of the various motor nerves engaged in speech, and by that peculiar form of paralysis described by Duchenne and Trousseau, and which the latter terms glosso-pharyngeal paralysis. Dr. Bristowe added that cases are certainly met with in which the above three varieties of loss of speech are combined in a greater or less degree. Dr. Bristowe concluded by stating that aphasia due to affections of the larynx, or of the pneumogastric nerve, or to hysteria, had all been abundantly investigated, but that he did not propose to dilate upon them.

A discussion ensued, in which Mr. Lockhart, Dr. Purvis, Dr. Gooding, Mr. Mitchell, Mr. Hope, Dr. Clapton, and Dr. Thorowgood took part, several of the speakers citing cases that supported Dr. Bristowe's views.

A hearty vote of thanks having been unanimously accorded to Dr. Bristowe for his highly interesting and instructive Paper, the Society adjourned.

SCOTLAND.

Edinburgh.—The Medical Education of Women. The Royal College of Surgeons of Edinburgh has held a special meeting for the consideration of the question of the medical education of females. The chair was occupied by Dr. Gillespie, the president; and there was a large attendance of members. It was moved by Dr. Andrew Wood, and seconded by Dr. Gairdner, treasurer of the College—"That, in the opinion of this College, it is neither proper nor expedient that males and females should be associated together in the study of medicine either in hospitals or in classes." An amendment was moved by Dr. Handyside, and seconded by Dr. Watson—"That, in the opinion of the College, it is not expedient that the College come to any resolution in regard to mixed classes." On a division, Dr. Wood's motion was carried by a majority of twenty-seven to four. A considerable number of the members of the College left before the division.

PUBLISHER'S NOTICE.

REDUCTION IN PRICE.

On and after the 1st of January next, the Annual Subscription to this Journal will be reduced to £1, post free, for Subscriptions paid in Advance—i.e., within the first three months of the year. Subscriptions on Credit will remain as formerly, at £1 2s 6d.

The MEDICAL PRESS AND CIRCULAR *will henceforth be the cheapest, as it is now acknowledged by impartial critics to be the most practical, and the only independent organ of Medical Opinion in this country.*

REGISTERED FOR TRANSMISSION ABROAD.

THE

MEDICAL PRESS AND CIRCULAR

Is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d. Stamped, 6d.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 28, 1870.

1870.

THE year is so rapidly closing that we naturally look back for a moment at its course, and may be excused for turning a moment from the awful scenes of its later days to a brief retrospect of some of the questions that have occupied us as a Profession. The year opened in the midst of a campaign for Medical Reform, and although good service has been done, it closes without anything having been accomplished. Sir John Gray's Bill, the Government Bill, and many other schemes—some good, some indifferent, most of them embodying both good and bad qualities—are all now consigned to the limbo of the past, and the only thing that remains is for us to learn from them, lessons that shall enable us to attain our wishes.

It is but a short time since we criticised the last effort at Bill making, and it is likely enough that very soon other projects will be announced. There is even a talk of Government once more offering to settle the differences of Medical Reformers. It becomes us, therefore, to be ready and watchful. What the Profession most lacks is unity. It is desirable for ourselves, and also for the public, that we should be a fraternity with some mode of action, not a mere aggregate of individuals. We ought to be a self-governing body—as distinct as that which constitutes the legal profession. In theory this has been recognised, but we have been divided into sections. The State committed us to corporate bodies, and these, instead of being representative of the Profession as a whole, have set up divisions and claimed to rule them. Thus, they have become an incubus. Hence, half our woes and half the dangers of the public. The Act of 1858 attempted to remedy this by combining these bodies into the General Medical Council. But vested rights, the rivalries of the Corporations, and the little power given to the Council, render the act almost nugatory. Had the General Council been a body representative of the Profession, and possessed of adequate authority, a great reform would have been accomplished. To make it such has been the effort of all true Reformers since its creation. It matters little as to the method if this can but be done. The most radical method is to sweep away all the Corporations as Licensing Bodies, but this has found little favour, as it would cut us adrift from revered histories, and cripple the resources of great and national institutions. To set up a council, such as that proposed lately by Mr. Hawkins, would act to some extent in the same way, and the proposal excites the anger of most of the Corporations. Nevertheless, the scheme of Mr. Charles Hawkins is simple and thorough, and unless rival interests come to some agreement to accept a less radical change, the Profession may insist upon having it. The scheme of Dr. Prosser James is much milder, though it might be found equally effective. We have more than once pointed out, that so far as the Council is concerned, it might have been carried out without an Act of Parliament, and that is one of its chief recommendations. Perhaps the doctor himself would be disposed to extend it, if legislation can be obtained. Still, when he first proposed it to Lord Palmerston he seems to have thought it would suffice. The Corporations secured more than it was intended to give them, and now are unwilling to cede much. Still, it is not impossible that something may be done, and that in 1871 this tiresome question may be set at rest.

Apart from an Act of Parliament, there is yet another chance of Reform. We have pointed out during the year that the Corporations might, by voluntary amalgamations, secure all the benefits that they now enjoy, and confer many others on the Profession. In Ireland much progress has been made, and great credit is due to the College of Surgeons in Ireland for its efforts in this direction. In England, too, some progress has been made, but the amalgamation has been prevented from being completed by some very ridiculous susceptibilities. If the several bodies will accept the principles laid down in an article "On the Chance of the Corporations," which appeared some months ago in the MEDICAL PRESS, it will be easy to refer the details to a committee of disinterested men who love their Profession. The superior Bodies could afford to be condescending. The inferior ones might gain in general estimation by not insisting too strongly on their rights. An umpire would soon arrange all that—and yet it is not done; and so we go on with our numerous licenses, and the competition downwards, which has done such incalculable injury. But time passes. Here we are at the end of 1870, and next year let the Profession insist on Parliament giving us that which our competing bodies deny—a single Board. At the same time let it give us the Representative Council we need so much, and the self-government through that Council which would be so beneficial to the public as well as to ourselves.

Another question that has greatly agitated professional circles this year is that of the Contagious Diseases Acts. A Royal Commission is now appointed to inquire into their working, and much medical evidence will, we hear, be taken. We have received, in respect to this and some other equally difficult and delicate subjects, a mass of communications, with which it has been no easy task to deal. We find, too, that some friends are greatly surprised at the toleration we have exhibited. In fact, we are told that we are "too tolerant by half." We accept the censure —if such it be—without regret.

On every question of importance to our Profession we have been ready to hear both sides, and we hope to maintain our character for impartiality, even at the risk of being too tolerant. To those correspondents who complain that their opinions have not been so fully supported in our columns as they wish, we beg to say they might themselves support them. Discussion should be as easy to them as complaint. It would be more satisfactory to us.

As we have touched on this point, we may as well repeat that not only on these, but on all questions, our columns are freely open to those who differ from us, and our constant endeavour is to be impartial.

We had intended when we commenced this Retrospect to pass in review other subjects, but must postpone them to another week.

LIFE ASSURANCE.—IV.

A SERIES of articles on Life Assurance in a Medical Journal would, however short, seem hardly in place, unless, before they closed, the subject were viewed from a medical practitioner's point of sight. Members of the Faculty stand in at least three special relations to the matter. They have to consider their duty to the community, their duty to their patients, and their duty to themselves.

Their duty to the community must be onerous indeed, if anything remain to be added to it beyond what has hitherto been deemed incumbent upon them. In strict morals, no doubt, every one of us, from Queen to quarryman, owes himself to his neighbours, to his nation, and to his kind. But the obviousness of this universal obligation increases upon the eye in proportion to the individual's qualifications to benefit his fellow-creatures, and to the importance of the things in respect of which he may be specially qualified. The more a man does the more he may do, has become a proverb, and one which threatens to overwhelm the physician and the surgeon beyond all men besides. The profession, however, is actuated by a spirit which will not allow its members to shirk or to shrink, although, while accepting impossible responsibilities, they must fain be content to do so much only as they really can.

Already the medical man is expected by the State to cure its acknowledged poor almost as gratuitously as he might any miserable patient picked up by himself on the roadside. Besides this, he is summoned to pay as close an attention to the sanitary condition of the town or the village in which he dwells, as if he were paid for it or had nothing else to do, his special qualifications for the service vastly increasing, of course, the value of the boon to his neighbours, but, as for himself, tending constantly to an increase of work absorbing time and energy, while yielding no pay. All the while, he is, by ungenerous minds, suspected of revelling in conditions prejudicial to health, and of grudging every measure adapted to remove or abate them.

Nevertheless, it is his duty to the State and Nation to devote himself to the general health, and, if we could conceive of that duty being performed so as to get rid of disease by getting rid of the tendencies to it, it would then become the duty of the State in return to consider by what means other than the payment of fees on behalf of persons under treatment, the community could best afford a maintenance to an order of benefactors who would be as necessary to keep up the anti-mortific condition of things as they were to bring it about. Meanwhile, the people and their doctors must get on together as well as they can. There is this to be said on the side of the doctors, that in proportion as wealth and intelligence increase and are spread, will the sense of obligation for relief under pain and sickness, and the power to express that sense in a substantial manner, be accumulated and abound. Then, too, it is considered that, as a High Authority has told us, the poor we must always have with us, that, among the poor, the most formidable diseases are apt to nidificate, and that, under such circumstances, the affluent can neither flee from, nor defy the virulence of infection, the medical man finds himself unable to resist the feeling that every form of motive, personal and public, urges him to give the full benefit of his knowledge, observation, and skill to the whole community through that portion of it among whom he habitually resides.

There is no platform on which the combination of interests comes more forcibly into view than that of the Life Assurance Office. The State has a deep interest in the stability, the efficiency, the universality of this form. Nothing she *does* tends more to relieve society at large from the burden of maintaining the poor. The remark is applicable to the country at large, but only because it is in the first instance more perceptibly applicable to every parish severally. For benefits like these we all are infinitely indebted to the Life Assurance Office. If the policies are punctually paid when they fall due, it reflects credit upon the medical examiners, if the policies fall due at early dates and in quick succession, a shade of suspicion is cast upon the degree of care and of penetration which they have exercised.

There are, therefore, strong reasons why the medical estimates of the value of particular lives should be most scrupulously formed. The insuring public, as those who furnish the Faculty with the most remunerative employment within their reach, have an unquestionable claim upon their good faith and intelligent pains, for the holders of life policies, at any given time, are injured by the taking of any life at ordinary rates which does not merit that place in the Company's books. On the other hand, every medical man, and especially the juniors, have a deep professional interest in the patient, faithful, conscientious exertion of their skill in the examination of persons offering themselves for insurance. This kind of practice affords a field for observation and a fund of experience such as ordinary attendance upon the sick members of families could never give, and the resulting gain to medical knowledge must be inevitably great. If, however, it be asked what solid benefit accrues to the members of the profession as men seeking a livelihood in common with their fellow-men, there is nothing to boast of in the very moderate fees paid for such examination. The best *quid*

pro quo that physicians and surgeons can get out of the Life Companies is, by taking out policies on their own lives. They deserve well to be received on the terms of "the most favoured nations," and, unless in very bad cases, would find most offices ready to accept them as among the more reliable class, from their superior knowledge how to take care of themselves. From reflection upon the precarious tenure of health in the sphere of their duties which necessarily exposes them to the constant vicissitudes of the weather, besides bringing themselves frequently into contact with people afflicted with infectious diseases, obviously the best course that they can pursue is, to insure their own lives. Like all other men who win their bread by exertion of hand and brain, and not by the fructifying use of a money capital, they have thus the means of providing a competency for their wives and families while they live, instead of leaving them to lament their connection with professional men whose means of supplying the wants of those dependent upon them ceased when the breath of life went out of their bodies.

Notes on Current Topics.

About the War and Wounded

What a Christmas time for the poor soldiers in the field. The strongest may well quail before the bitter weather we have lately had. What then can be the condition of the sick and wounded, and especially of those unfortunate wounded left on the battle-field without help? Such a demon's dance as this cruel war has set up in Europe is enough to make angels weep over the madness and ambition that has relentlessly plunged the race in war. We, in our island home, as yet unvisited by the dread scourge of war, cannot but feel some pain at the thought of the misery being endured by brave men. The thousand homes of Germany and France must vibrate with emotion at the thought of what their absent members are enduring; those men themselves, their agonies are indescribable. When shall this cruel war come to an end?

***

Nothing has proved itself so helplessly incompetent as the Intendance Department of the French army. The probability of this proving to be the case was well known years ago, but the authorities refused to take warning; it is therefore anything but assuring in such times as these to be told that the Control Department of the British army is similar in plan, and possesses all the vices that have added to the miseries of the French wounded. It is useless for Professional writers to say more. The medical journals have always been warning the public, but their complaints make no impression. We appeal to our brethren of the lay press, now that army reform commands some attention, to waken their readers to the fact that the Army Medical Service is discontented, and that not without reason.

***

A correspondent describes the district of Sedan, where the houses were mostly used instead of tents, as in a sad condition. These temporary hospitals, situated in lovely districts, looking out on most picturesque views, were but hot-beds of disease. Pyæmia, dysentery, and other miseries were rapidly reducing the numbers of unhappy sufferers. Here and there want of care and cleanliness may be seen, but in the best regulated places pestilence was raging.

***

The Belgian and Dutch surgeons have largely employed plaster-of-Paris to put up broken limbs. We are told that in some cases the shortening was very great. It is to be supposed that in the hasty setting brought about by the large numbers, many such cases must have occurred.

***

The German surgeons use plaster-of-Paris bandages to a large extent. They put up fractures in this way at a very early date, and that in the simplest mode. The bandages are merely soaked in the liquid plaster, and applied to the limb without anything underneath. Occasionally a piece of pasteboard is used to give more support at the fractured part. Holes are cut opposite the wound after the plaster has set. Swelling sometimes takes place to a considerable extent, and gives rise to mischief, especially as the foot is mostly left uncovered by the bandage.

The terrible miseries of some of the wounded is related by the *Times* correspondent with the Saxon Army Corps, at Le Vert Galant, who writes:—"As many as 1,500 French prisoners have been despatched from Lagny in a single train. On a recent occasion, when one of those trains stopped, some provisions were distributed to the prisoners by Captain Neville and Mr. Sutherland. The poor fellows clamoured for the food. Out of every carriage there was a cry of '*Ici!*' and when they got the provisions they ate them ravenously. The pressure and actual want are to be attributed to the two battles of the 30th ult. and the 2nd of December. So many wounded were removed to Lagny and its neighbourhood that it was not always possible to find food even for them.

***

With such miseries going on we are glad to hear that the French Government is doing what it can, and that a decree creates six depôts for convalescent soldiers—viz., at Nantes, Bayonne, Toulouse, Montpellier, Perpignan, and Nice.

***

Late advices from Le Mans describe the town as in a state of the greatest confusion. Regiments were constantly arriving, to find that no preparation has been made to receive them. They have neither food to satisfy their hunger, nor beds on which to rest their limbs. From early morn to dewy eve bodies of men from the Army of the Loire were continually pouring in. The appearance of the men was most pitiable. Their arms useless from rust; many without boots; several completely done up; the cavalry even, if possible, in a worse state than the infantry. In many cases the soldier helped the horse, not the horse the soldier, to cover the ground; for the wretched animals were hardly able to crawl along.

***

An equally wretched scene occurred at Alençon. The town was filled to overflowing. The soldiers were billeted everywhere, and one out of every three houses displayed the ambulance flag. Nay, the very streets bore witness to the miseries of the war, for they were crowded with carts

laden with the wounded. One moment, an officer tells that two-thirds of the regiment to which he belongs has been lost; the next, an officer passed whose regiment actually no longer exists.

* * *

A correspondent stated last week that there were *six thousand* wounded between Blois and Orleans, *destitute of medical assistance.*

Among the wounded at Arras, one man had received a ball on the side of his nose, which had penetrated the palate, and then gone down his throat, leaving no clue to discover its whereabouts.

A shell fell upon one man, and exploding, tore both his hands from his wrists, without doing him any further injury.

A bullet struck one near the left temple, instantaneously making its way to the shoulder, remaining in his arm for some time, and finally emerging at the elbow.

Lord Stanley on Health.

In his able address last week Lord Stanley said to some men starting in life :—

"Let them recollect that the race in which they are engaged is one which will last all their working days, and in which endurance is more important than speed. They knew already that intemperance is one form of suicide—let them remember that all neglect of physical laws is open to the same reproach, and that there may be intemperance in work as well as in meaner indulgences. You cannot have mental efficiency without health; you cannot maintain health in an exciting and exhausting employment, such as most mental occupations are, when eagerly followed, without some care to preserve it. What I had to tell you about keeping up literary tastes has been said already. They are a great pleasure—a wholesome and a lasting one. Keep them up if you can, and as long as you can. But while you do that, remember also that there is one thing as compared with which not only material health and luxury, but all art, all literature, all science even, are relatively unimportant, and in regard to which the poorest labourer may compete with any of you on equal terms—I mean a steady, untiring performance by each individual of his public and private duty."

Presentation to Dr. Waring-Curran.

A very handsome testimonial was last week presented to Dr. Waring-Curran by the inhabitants of Sutton-in-Ashfield, on his leaving the neighbourhood to succeed the late Dr. Macnamara at Mansfield Woodhouse. The testimonial consisted of a massive gold chain, with ornaments set with blood stone and onyx; a beautiful ring, set with a large carbuncle, and a surgical instrument of considerable value.

"The Technical Educator."

Everyone is acquainted with the "Popular Educator," issued in numbers and parts, by Messrs. Cassell, Petter, and Galpin. The new edition seems to have been as successful as the first. The same enterprising publishers have commenced a new serial "The Technical Educator," which promises to do for applied science, what its predecessor has done for general education. There can be no doubt that technical education has now come to the front, and from what we have seen of this new serial we believe it will accomplish all that can be expected of it. In Part I. are several articles of direct interest to our Profession. The articles on agricultural chemistry are written by Dr. Cameron, the learned Professor at the Royal College of Surgeons, in Ireland, and the mention of that name is sufficient guarantee to our subscribers of the solid value of his contributions. Again, "Applied Mechanics" is written by Professor Robert Hall, of the Dublin College of Science. Mr. George Gladstone, F.C.S., contributes articles on "Chemistry Applied to the Arts." There are many other subjects that will come forward as the "Technical Educator" proceeds, in which the sciences most cultivated by our Profession will be elucidated as to their applications; besides which, drawing and art in all its branches is completely treated. We heartily wish the new serial as great a success as its predecessor.

Education at Leamington.

The College at Leamington is making progress, and a new boarding house has just been opened in connection with it. This building forms the western side of the quadrangle of the Elizabethan structure of Binswood. The proceedings were initiated by the Lord-lieutenant of Warwickshire, Lord Leigh, patron of the College, and he was surrounded by the *élite* of the county. It was expected that Dr. Barry, formerly head-master of Cheltenham College, the Bishop of Exeter, and other leading educationalists would have been present, but they were, unfortunately, prevented from attending. Amongst those who took part in the proceedings were—Dr. Jephson; Dr. O'Callaghan, F.S.A.; the Rev. H. G. Woods, Fellow and Tutor of Trinity College, Oxford, &c. The new boarding-house has the residence of a master attached to it, under whose management it will be conducted. The basement and ground-floor contains various requisite offices, also a spacious dining-hall, a school-room, as well as several private studies, which will be placed at the disposal of the most diligent boys. The upper floors contain forty dormitories, bath-rooms, and other apartments; also separate rooms for invalids. The whole is well heated with hot water, and thoroughly ventilated. The staircases are of stone. No expense has been spared to ensure health and comfort in the minutest particular. During the proceeding the scholarships gained by the students in open competition were awarded.

Spread of Fever by Cabs.

Last week a police inspector applied to Mr. Paget for a summons against a man for hiring a cab, and riding in it, without giving due notice to the driver that he was suffering under typhus fever. He also applied for a summons against the driver of the cab for not disinfecting his vehicle after his engagement. Mr. Paget said that in the public interest this was a very important and proper prosecution, and he should certainly grant the summons. It should be made known that persons labouring under a malignant fever, or small-pox, who rode in cabs and other public vehicles, without previously giving notice of their malady, were liable to heavy penalties, and the drivers of vehicles were also equally liable if they did not properly disinfect their cabs after carrying fever patients.

Skin-Grafting Superseded.

Recent statements on the interesting subject of skin-grafting seem to show that they were mistaken who at first thought it necessary to transplant pieces of skin of any

depth. All observers now agree that the first phenomenon is the disappearance of the characters of true skin in the piece transplanted, which becomes a mere pellicle. Further, there should be no trace of areolar or adipose tissue left, and Dr. Fiddes says that there is no necessity to take any skin, but merely a few epidermic scales. We would now suggest the trial of a popular plan that we know proved successful years ago, and which is known as a favourite one with many a village "lady-bountiful." The so-called "skin of a new-laid egg" laid carefully on an old ulcer, and left there for some days, is the popular cure to which we allude. The egg must be new-laid, and the pellicle carefully spread out over the ulcer. The membrane can be very easily separated from the shell to which it generally adheres, when the egg is broken. In a case communicated to us this week it was completely successful, after years of ordinary treatment had failed. It may be worth the while of surgeons to make an experiment or two with this popular remedy.

Naval Medical Reform.

Dr. Brown, of Rochester, has collected information from officers of all ranks as to the causes of discontent with the Naval Medical Service. We have so often dwelt upon the subject that we need only repeat once more that the surgical staff only asks for justice.

Illegality of the proposed Irish Unions Apothecary Appointment.

The Irish Medical Association Journal of last week publishes a very important opinion emanating from one of the most eminent Queen's Counsel in Ireland, and condemning, on legal grounds, the proposed appointment of a Poor-law Apothecary General. Counsel says:—

Upon the best consideration I can give this question, which is one of some difficulty, I think the Order of the Commissioners in the form in which it is issued is not warranted by the Act.

The Commissioners may, under the ninety-second Section, desire any number of Unions to join in the making of any contract, although I do not think this provision was ever intended to authorize a general combination of all the Unions in Ireland into one. The words of the section authorize it, and I do not think that so far as it desires all the Unions in Ireland to join in one contract for medicines it is illegal, although I think it is a straining of their powers to a purpose for which it never was intended.

But it appears to me, that the Commissioners have gone beyond their authority in giving the new officers to be appointed power to enter into contracts on behalf of the Guardians. The only power conferred in any section of the Acts that I can discover, and the only power that I can find in the statutes giving power to anyone to make contracts binding the ratepayers and enforceable against the rates, is that contained in the 27th Section, allowing the Board of Guardians to contract.

I therefore think that the Order of the Commissioners enabling the newly elected officers to contract on behalf of all the Unions in Ireland is illegal. I think no contract can be made binding on the ratepayers except by the Board of Guardians.

It is plain that, if the Commissioners have this power, all control over contracts can be taken away by a General Order, and vested absolutely in one official, empowered to contract on behalf of all the Unions in Ireland.

It appears to me, that the only way of testing the legality of the Order is to apply for a certiorari to bring it up to the Queen's Bench to be questioned. I think this Order could be applied for on the part of any Board of Guardians in their corporate capacity, or any *interested* ratepayer, or guardian or ratepayer. I think it questionable whether it could be obtained on the application of a contractor for the supply of Medicines to a Union under an existing contract.

It is not necessary to give any opinion as to the power of the Commissioners to compel any Board of Guardians to join in any specific contract which is laid before them, and which they refuse to make. Such a power is entirely different from one authorising an officer to bind the Guardians by contracts, in their name, of which they never hear. I think the Commissioners have full power to make any regulations as to contracts for the supplying of Medicines which they may think necessary to insure a pure supply of Medicines. In my opinion, the Commissioners have no power to delegate to anyone, or rather, confer on anyone an authority to make contracts in their name.

The Editor of the Irish Medical Association Journal considers that this opinion, taken in conjunction with the universal disfavour with which the Commissioners' proposal has been received by the Irish Guardians, disposes finally of the scheme embodied in the sealed order.

It is here distinctly stated that although the Commissioners have power to order the various Unions to join in making a contract, they have no legal right whatever "To delegate to any one, or rather to confer on anyone, an authority to make contracts in the name of the guardians." It is, therefore, evident why the appointment of an officer was given to the Guardians. That officer could have no power whatever, unless in virtue of his appointment by the Guardians. By joining in the election, or assenting to it, the guardians would be assigning to the officer their power to make contracts; but if they do not so alienate their privilege, there is, it seems, no power in the Commissioners to take it from them, and they would be still entitled to make their own bargain and to repudiate any bargain made for them by the Poor-law Unions' Apothecary.

The issue is, therefore, entirely at the disposal of the Guardians. If they disapprove of the form which the action of the Commissioners has taken, they free themselves entirely from its operation, by declining to join in making any appointment, and if they take this course, the central officer will be restricted in his control to those unions which endorse his election.

Vanity Fair gives in its cartoon a caricature of Sir William Fergusson. Neither the picture nor the biography, in our opinion, do the worthy baronet justice.

It is said that the Factory Acts have been completely disregarded lately at Woolwich Arsenal. We are not aware that Government has any protection from the evils intended to be removed by the restrictions imposed by Parliament. The subject demands some explanation.

It has been decided by the Fellows of the London College of Physicians to publish an annual statement of accounts. This College is progressing rapidly in public favour, and we hope soon to see the Fellows meet the wishes of the Members, and the whole College take its proper position at the head of the Profession.

One of our medical contemporaries states that new forms for statistics relating to convicts are coming out, and remarks that the medical officers of prisons are in a position to make returns of a most interesting and valuable character. Hygiene, diet, and many subjects might be admirably investigated by the members of our Profession, who have under their care numbers of criminals; and, although some points are alluded to in the usual statistics, it is surprising that they have not been elucidated more thoroughly.

The sum total of the collections on "Hospital Sunday" at Birmingham this year amounts to £4,025, being the largest sum ever yet collected for the minor charities which by rotation take this year's proceeds.

Literature.

BIRD'S PHYSIOLOGICAL ESSAYS.*

The Essays offered us by Dr. Bird are "On Drink-Craving," "Differences in Men," "Idiosyncrasy," and the "Origin of Disease." The three first appeared in the *Indian Annals of Medicine*, 1863—5 and 8. The last has been published in the *Indian Medical Gazette* for the present year. Collected they form an octavo vol. of nearly 250 pages, and they will be found of interest beyond professional circles. Dr. Bird has collected many valuable facts, and has marshalled them with skill, but he is far from having established the theories he maintains, and we must regret that he should exhibit such a strong materialistic bias. To maintain that the time will come when we can predicate the actions of individual men, as we may now those of the heavenly bodies, is a proposition that will turn away many a reader from the book in which so unworthy a proposition is seriously put forward. It is contrary to all human experience to expect that every variety of thought and feeling is but the effect of variety of structure. The individuality of every person is something essentially connected with life, and when the vital spark has fled, the materialist cannot discover any change of structure to account for the great change that has taken place. What right, then, has an author to assert that love is nothing more than "a condition of our tissues;" or that an individual will be avaricious, intellectual, ambitious, or otherwise minded, "according to the tissue in which the point of attention, around which the cerebral motions gather, is oftenest placed?" This certainly beats phrenologists themselves.

The essay "On Drink-Craving" is just now full of interest. What medical man has not been troubled with cases that he knew not how to manage or advise about? Dr. Bird advocates the establishment of Drunkards' Reformatories; but legislation in this direction is on every hand felt to be surrounded by difficulties, and a very large proportion of Englishmen would regard it as an uncalled-for interference with the liberty of the subject. Dr. Bird has no sympathy with teetotallers; he looks upon a desire for stimulants as a natural appetite, which in drink-craving is morbidly exaggerated, and he attacks with great power Dr. Carpenter's extreme views.

In the essay "On Idiosyncrasy," Dr. Bird relates a number of remarkable cases. The last essay "On the Origin of Disease" develops a theory in twenty distinct paragraphs, of which the last gives some notion of the whole, and which is as follows:—

"The theory of disease above expressed may be named the heat or force theory in contradistinction to that which is known as the poison theory. It rests on the broad and sure basis of physical science in all its departments, and by means of it we are connected and interwoven, not only with the earth and everything that moves on it, but with the sun, the moon, and all the radiant stars."

FLOWER'S OSTEOLOGY OF MAMMALIA.†

This manual, if we may so call it, comprises the substance of the learned author's first Course of Lectures, delivered at the Royal College of Surgeons of England, during the present year, and it is a work for which we venture to predict a great success. Comparative anatomy has been too much neglected, but now it is likely to step into its proper place, and the bony framework of animal bodies is the part around which all is built, and which not only demands the first attention, but is from various causes the easiest to study. With the present Hunterian Professor as a guide, any student will find his path considerably smoothed, while he is in no danger of having to unlearn what he has acquired. Indeed, the student is under considerable obligations to Professor Flower for giving him so capital a handbook; and the publishers deserve credit for having brought it out in a form worthy of the author. We may remark that no more technicalities are employed than are essential, and that theoretical views are mostly excluded, so that those who desire to begin to study the animal kingdom have only to obtain the book before us. The numerous illustrations are faithful copies from nature, and greatly assist the comprehension of the text. They are mostly taken from specimens in the Hunterian Museum, and they reflect great credit on the artist, Mr. R. W. Sherwin. Professor Flower's is the best Text Book of the subject.

* Physiological Essays. By Robert Bird, M.D., Bengal Army. London: Trübner and Co. 1870.

† An Introduction to the Osteology of the Mammalia. By Wm. H. Flower, F.R.S., Hunterian Professor at the Royal College of Surgeons, and Conservator of the Museum. London: Macmillan and Co. 1870.

CURRENT LITERATURE.

Among new editions we have to announce Mr. Barwell's work on "Lateral Curvature of the Spine," of which the second edition, enlarged, is sent us by Messrs. Macmillan and Co. There are a number of new pages and new illustrations, chiefly to assist in diagnosis.

Dr. Gull's "Harveian Oration," delivered at the Royal College of Physicians on the 24th of last June, is now issued in a complete form by Messrs. Churchill. We gave an abstract of it at the time and therefore need only announce it.

Mr. Lund has reprinted (Cornish) from the *Manchester Medical and Surgical Reports* his two careful essays "On the Treatment of Wounds" and "Excision of the Knee-joint." Mr. Lund ably sustains the position he holds in the Manchester School and the Royal Infirmary.

Another Reprint worthy of mention is that of Dr. Keyes, from the *New York Medical*, of November, "On Syphilis of the Nervous System." (Trübner and Co.) It is a clinical study founded on cases by Professor Van Buren and the author.

Dr. Cleveland, President of the Harveian Society, publishes his Annual Address of last October "On the Modes of Dying, and the means of obviating the Tendency to Death." (Churchills.) The address is worthy of attentive perusal.

Dr. J. G. Davey reprints from the *Journal of Mental Science* his paper "On *Felo-de-se*," (Bacon, Lewes), which was read at the meeting last August, and contains useful hints and suggestions.

Dr. Tilt's Third Edition of the "Change of Life" (Churchill's), seems almost to demand at our hands a longer notice than we can give it in this place. It being so well established as a favourite book, must, however, be our defence for merely remarking that the author seems to have revised it with great care; and, in doing so, to have passed in review all the really valuable additions to the literature of the department of practice he follows, since his last edition was issued.

Gleanings.

Carbolic Acid in Surgery.

Professor Bardeleben (*Berlin Klin. Wochenschr* vii. 8, 1870), whilst strongly in favour of Lister's method, allows that several disadvantages attend it; such as the hindrance to the growth of granulations, the caustic action, and the occasional symptoms of poisoning. He has found that these disadvantages may be avoided without the good effects being lost, by using the sulpho-carbolate of zinc, as recommended by John Wood. In the same journal Professor Langenbeck states, that for six or eight months he has altogether abandoned the use of the permanent water bath in cases of severe injury, as he has found as good effects from the carbolic acid dressing, with less inconvenience. He recommends dilute solutions, one to six or eight, as most suitable.

Quantity of Carbonic Acid Contained in the Air of School Rooms.

Dr. Breiting (*Chem. News*) made a series of fourteen experiments, beginning at 7·45 a.m., and continued to 4 p.m., in a room of 251·61 cubic metres' capacity, and containing sixty-four children. The quantity of carbonic acid contained in the air of that room during these experiments varied from 2·21 to 9·36 per cent., while free open air contains four ten-thousandths of that gas; and a quantity of 1 per cent. of the same gas present in air is considered injurious to health.

Purification of Chloral Hydrate.

Prof. F. A. Fluckiger states (*Pharm. Cent. Hall*) that much of the commercial chloral hydrate is impure, and unfit for use until purified. It is usually met with in irregular masses containing moisture, and having a sharp, pungent odour, indicating partial decomposition. The salt may be readily purified by dissolving it in *pure* bisulphide of carbon (soluble in forty-five parts of the menstruum at 18° C.) and allowing the salt to re-crystalize by the spontaneous evaporation of the solvent. The product appears in colourless prismatic crystals, not hygroscopic, and free from acid reaction.

The Relief of Pain after Surgical Operations.

M. Sedillot has recently communicated to the French Academy his views in regard to the use of electricity in surgery, which are translated in the *Bowdoin Scientific Review*. After calling attention to the fact that surgical operations are now usually conducted while the patient is in a state of absolute unconsciousness induced by ether or chloroform, he remarks that, upon the termination of the anæsthesia, the patient wakes to suffer severe pain. Opiates, refrigerants and chloral have been tried to wholly remove the pain, but without success. The alleviation is slight.

M. Sedillot states that the cauteries, both potential and actual, and the electric cautery, render cut surfaces insensible and free from accidents. But certain causes have interfered with their extensive adoption for the relief of pain in surgery. The hot iron answers far better than the potential cautery, but it cools very rapidly and must be often re-heated. Its action is very superficial. Nelaton has employed the flame of illuminating gas, another has suggested the use of the jet produced by the ignition of hydrogen and oxygen.

Far better than any of these must be ranked the *electric* cautery on account of its intensity and the ease with which it can be managed. Professor Middendorpf, of Breslau, in 1854 published a description of a serviceable apparatus for electric-cauterization, but he states that in order to produce the best effects with the apparatus, it is necessary to produce merely a dull red heat of the wires. This, to be sure, is a heat sufficient to prevent any loss of blood, but is not enough to cause absolute dryness of the cut surface. Sedillot advises the use of a white heat in the electric cautery, as he secures by this means all the advantages claimed for the other degree of heat, together with additional advantages now to be mentioned. The remarks made upon the painlessness of severe burns must be given in the words of the author (translated):

"Burns of the third degree cause little pain. We have seen persons fatally burned who retained for some days their appetite, ability to sleep and even a hope of recovery. A workman who had thrust his foot into a stream of melted metal and drawn it out completely charred, did not suffer pain. A young girl whose garments had taken fire ran, frightened and in flames, down four flights of stairs and was complete scorched from head to foot. Yet in the short time during which she lived after the accident, she suffered scarcely any pain. After her death the skin was dry, tense and without any pliability, giving to the body the appearance of a brazen statue. This painlessness, which is a matter of general observation, is to be explained by the destruction of the nerves. The heat from the electric cautery in like manner renders wounds insensible, and it is easy to understand that patients treated by this method, while under the influence of chloroform (which we do not always employ) should complain of no pain upon their waking. A little later, say from the third to the ninth day, an inflammatory reaction commences, usually very slight indeed, and of very short duration. Wounds covered by eschars are less exposed to contagions and infections of a miasmatic, putrid or purulent character than wounds produced by cutting instruments. On account of this fact, the first possess a great superiority over the second. Liquids cannot be extravasated nor altered, and the repair goes on rapidly in these subcutaneous wounds."

The apparatus used by Sedillot is very simple, consisting of wires, or plates of platinum introduced within the circuit of a galvanic battery. These, as is well known, become intensely heated, and the degree of heat is perfectly within control.

In Sedillot's clinic, many operations have been recently performed by this method. Among these may be mentioned the removal of dermo-fibroid tumours, cancroid and cancerous growths, and direct destruction of a fibro-epidermic tumour of the nose. In no case has any accident followed the use of this cauterizing plate or wire. Sedillot gives the following as his conclusions: *a.* The electric cautery (electro-thermic) prevents pain after the operations; *b.* prevents loss of blood; *c.* prevents retention and alteration of fluids; *d.* prevents infections, putrid and purulent complications; *e.* presents the most favourable condition of sub-cutaneous wounds; *g.* is absolutely under perfect control, so that tissues may be changed to eschars, or carbonized, or even volatilized, as occasion may require; *h.* clinical experiments place electro-thermic among the most remarkable improvements of modern surgery.

Medical News.

Royal College of Physicians of London.—At an extraordinary meeting of the College, on Monday, the 19th inst., the following gentlemen, having conformed to the bye-laws and regulations, and passed the required examinations, were granted licences to practise physic, including therein the practice of medicine, surgery, and midwifery:—Alexander Cummings Air, M.R.C.S., 33 Lorrimore square, London; Ernest Richard Evans, M.R.C.S., St. Bartholomew's Hospital; Samuel Evans, M.R.C.S., 23 Manchester street, London; John Howe Hughes, M.R.C.S., Gosforth, Carnforth; William Kipling, M.R.C.S., Ronaldkirk, Darlington; Francis William Pittock, M.R.C.S., "The Elms," Ramsgate; Alfred Risdon, M.R.C.S., 67 Warwick street, London; William Egerton Saunders, M.R.C.S., Guy's Hospital; Charles Lyon Vasey, M.R.C.S., 5 Cavendish place, W.

Apothecaries' Hall, London.—The following gentlemen having passed the necessary examinations were admitted licentiates of the Society of Apothecaries, on the 22nd inst., viz.:—Messrs. R. E. Deane, of Batley, Yorkshire; E. R. Evans, of the Evelina Hospital, Southwark; E. T. Hughes, of Anglesea; A. K. Longhurst, of Farnham; W. H. Nethercliff, of Whitchurch; and E. Wykes, of Birmingham. At the same Court the following passed the primary professional examination, viz.:—Messrs. F. I. N. B. Elliot, J. Kindon, R. A. Lithgow, G. J. Llewellin, C. E. Whittington, and E. G. Younger, all of Guy's Hospital; J. H. Penkivil, and W. A. Ward, of St. Bartholomew's Hospital; W. Penton, of the Leeds School of Medicine; F. H. Spencer, of King's College, London.

University of Dublin.—The following degrees were conferred on the 14th inst.:—Bachelor in Medicine—Charles Dunscombe Allen, William Thomas Briscoe, Reuben Joshua Harvey, William Hugo Lambert, Henry Marcus Levinge, Alfred Henry Martin, Richard George O'Flaherty, Edw. Albert Rawson, Hatton Smyth, Wm. Henry White, Joseph Wm. Neligan. Master in Surgery—William Thomas Briscoe, Reuben Joshua Harvey, Edward Albert Rawson, Hatton Smyth, William Henry White. Doctor in Medicine—Robert Thomas Cooper, William Hugo Lambert, G. George Smith, Anthony Traill.

In the eight principal towns of Scotland the deaths of 2,254 persons were recorded during the month of November. The mortality was considerably below the average. Fever caused 129 deaths, of which 81 occurred in Glasgow. Relapsing fever is spreading extensively in Glasgow, and is also manifesting itself in Paisley and Greenock. Scarlatina was most fatal in Aberdeen, where it caused 10 per cent. of the total mortality. Measles caused 17 per cent. of the deaths in Paisley.

Dr. Philipson's sickness returns show that the total admissions into the Newcastle Fever Hospital during the months of September and October amounted to 90; of which 23 were cases of continued fever, 7 of enteric fever, and 60 of typhus. In the corresponding period of 1869, 18 cases of typhus were admitted, 30 in 1868, and 79 in 1867. Many of the last October admissions were of a mild type.

The retirement of Dr. Mouat.—"The retirement of Dr. Mouat from the Inspectorship of Gaols in Lower Bengal has caused a little difficulty. His place has been filled by Dr. Fawcus, his late deputy, a capital gaol-manager, only altogether out of the groove of seniority; and, indeed, not yet a surgeon, only assistant-surgeon. Dr. Norman Chevers, a gentleman, perhaps at the head of the Profession in India, is held to have had the prior claim in every way; and, it is said, that he was quite willing to accept the post. On the other hand, it is argued that Dr. Chevers would very soon, from age, be unequal to the great labour of such an office. The appointment rested with the Lieutenant-Governor of Bengal; and he is charged, as usual in such cases, with giving his decision on narrow grounds, which, I should say, is the reverse of the fact. Whatever else may be said of the appointment, Dr. Fawcus certainly has proved himself the man for gaol-management, and in that light the question would be viewed by Sir William Grey. No one, however, hints that Dr. Chevers would not also have proved a good gaol-superintendent; and everyone admits his high attainments, character, and claims. The dispute, however, is purely a parochial one, and sways to either side according to the feeling of the advocate. Dr. Mouat has been mentioned in some quarters as a gentleman eminently entitled to the Star of India, which has never yet been given to a medical man for purely civil services."—*Times' Correspondent.*

A Good Opening for a Medical Man.—At an inquest held by Dr. Lankester, at the "Cock and Hoop," West-end, Hampstead, on the body of Mrs. Matilda Newman, a highly-respectable person, it was elicited that Dr. Winter did not arrive at the house of deceased until three and a half hours after death had taken place, which was from heart disease, the medical gentleman, when sent for, being out on his list of calls. The friends did not send for another doctor because there was none in the neighbourhood. Dr. Lankester said that, though strange, it was true that there was only one medical gentleman near the spot, the population of which was now some thousands; and having a new lord of the manor there was some prospect of building operations being carried on, and a great addition to the population, and it was a capital chance for a medical gentleman to obtain a good practice.

Quackery.—At Bow street, John Hamilton, M.D. (query of what University), of 404 Oxford street, was charged with causing obscene medical tracts to be distributed to youths in the public street. Mr. Vaughan fined the defendant 40s., and ordered him to pay the costs of the summons, and £1 1s., the costs of Mr. Collette, who prosecuted on behalf of the Society for the Suppression of Vice.

Richard Harvey, Esq., of Greenway and Torquay, Devon, bequeathed the following amounts (among others), payable on the death of his widow—namely, £4,000 to the Royal Hospital for incurables; £4,000 to the Hospital for Paralysis; £4,000 to the Hospital for Consumption, Brompton; £3,000 to the Cornwall Infirmary; £3,000 to the Asylum for Idiots; and £2,000 to the Cancer Hospital, Brompton. The Rev. J. H. L. Gabell has sent £1,000 to the Board of Cheltenham Hospital, to be applied either towards the erection of a fever infirmary, or to the ordinary funds of the hospital. Charles Stuart, Esq., of London and Bishopstoke, bequeathed £200 each to the Hospital for Sick Children, Great Ormond street, and the Middlesex Hospital. The Aberdeen Royal Infirmary has become entitled to £500, under the will of Dr. Tawse. Mr. F. A. Schroeter has given £100 to the Royal Free Hospital, "in memory of his son." The Dental Hospital of London has been presented with £21 by the Grocers' Company.

How to clear the Streets of Snow.—Our public arrangements are wretchedly bad, and positively provoking. Year after year the streets are blocked with snow or dangerous with ice, yet nothing is done to remedy the evil. There is no practical difficulty in rendering both road and footways perfectly safe for man and beast. As we have repeatedly urged, it is only a stupid economy that prevents our employing the thousands of poor whom we *must* relieve, with or without industry, in the useful labour of cleansing the streets at this season. Two hours work before breakfast would be hailed by those who are the most deserving of their class, and it would amply suffice to place the streets in excellent condition, before the busy traffic of the day begins. The extra expense thrown upon the parish would be very small indeed, and the result a real benefit.—*Globe.*

Cattle Plague.—Cattle plague is at present reported to exist in Austria, in the provinces of Transylvania and Galicia; in Belgium, in the districts of Jamoigne and Bloid; in France, in Alsace and Lorraine, Seine and Marne, the Ardennes, and the Moselle; in North Germany, in Prussia, Rhenish Prussia and Brandenburg, in Pomerania and German Lorraine; in South Germany, in Bavaria, Baden and Wurtemberg; in Russia, in Poland, places opposite East Prussia, and at Riga and its vicinity; in Turkey in Asia, on the north-east coast of the Black Sea; in Turkey in Europe, in Thessaly and Roumania. Pleuro-pneumonia exists abroad, in Holland, North Germany, and Turkey in Asia; at home, in thirty-six counties in Great Britain. Foot and mouth disease exists abroad, in North Africa, many parts of South America (especially on the north of the Rio Nigro, and on the side of the river Uruguay), in Denmark, France, Italy, and the United States; at home, in sixty-three counties of Great Britain. Sheep-pox exsits abroad, in North Germany, and Italy. Sheep-scab prevails abroad, in North Germany, and is reported to exist at home, in thirty-three counties of Great Britain.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column, are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Out of thousands of such persons it may cause enquiries so signed, on very various subjects much confusion.

Notice to Members of the Irish Medical Association.—This being our "Index Number," we are prohibited by Post-office restrictions from issuing the weekly official Supplement of the Association. Subscribers will receive their copies intact, as usual, next week.

Dr. S.—See our last number.

J. C.—You should make application at 2 Soho square.

A Provincial Surgeon.—Look among the Hospital Reports in the volume for the information you desire.

Enquirer.—Our notes "About the War and Wounded" will be continued for the present.

M.R.C.P. Lond.—Declined with thanks.

J. S., Glasgow.—The information you desire is among our "Notes on Current Topics" for this week.

Z. Z. Z.—Will appear next week

A Paris Doctor asks respecting the story of the Prussians having ejected the French wounded from a Belgian (!) ambulance at Versailles (?)

Alpha.—We commend to your notice the lately published letter of a French lady sojourning in this country, on the incapacity of Englishwomen in what, she says, Frenchwomen consider to be the first duties of their everyday life——knowing how to mend, to cut out, sew, knit, wash, cook, to look nice and make all around you look nice, even with the smallest means. She asks, "Why do not Englishwomen know a little more about the plainest elements of cookery?" In conclusion she says: "When I hear of ladies' brains busied upon such subjects as the Contagious Diseases' Act, and then see my landlord's very intelligent and nice little daughter of twelve, who can neither sew nor knit, although she goes to school, I marvel why clever and influential women will *chercher midi à quatorze heures*, and not seek to remedy evils nearer and more fitted to their Christian efforts."

A Naval Officer.—The *Army and Navy Gazette* states that a proposal is now under consideration of the proper authorities that all candidates for the naval medical profession shall be allowed to proceed to Netley, there to take advantage of the instruction provided by the admirable school which is to be found at that institution. It is intended that the gentlemen nominated for the military, naval, and Indian medical services shall enjoy equal privileges during their term of residence.

VACANCIES.

Royal Surrey County Hospital.—Medical Officer. Election February 23rd.

Brompton Consumption Hospital.—Resident Clinical Assistant.

Shrewsbury Infirmary.—Dispenser. Salary £70 per annum.

Killarney District Lunatic Asylum.—Resident Medical Superintendent. (See advt.)

Clonmel District Lunatic Asylum.—Assistant Resident Physician. Salary £100, with board, &c. (See advt.)

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Body and Mind. By Hy. Maudsley, M.D. London: Macmillan and Co.

A System of Surgery by various Authors. Edited by Timothy Holmes, M.A., F.R.C.S. Vol. IV. London: Longmans, Green, and Co.

Il Medico Condotto; New York Medical Gazette; Nature; Chemist's Advocate; Boston Medical Journal.

APPOINTMENTS.

Cavanagh, J. W., L.R.C.P., Surgeon to the Main Bridewell, Liverpool.

Donovan, D., jun., M.D., L.R.C.S.Ed., Medical Officer for the Union Workhouse, Skibbereen, Co. Cork.

Douglas, W., M.D., L.R.C.S.Ed., Deputy Superintendent of the Criminal Lunatic Asylum, Broadmoor, vice Wm. Orange, M.D., M.R.C.P.L., promoted to Resident Medical Superintendent.

Fenton, M. A., M.B.T.C.D., L.M., L.R.C.S.I., House Surgeon to the Coventry and Warwickshire Hospital.

Holland, J. C., L.K.Q.C.P.I., House Surgeon and Resident Apothecary to the Cork North Charitable Infirmary.
